Lighting Installation for a Church Auditorium

Modern Lighting System Provided for Asbury Methodist Church in Rochester — Chiefly Indirect Lighting with Luminous Bowl and Urn Fixtures—Concealed Sources for Direct Lighting of Platform

By H. O. STEWART

Engineer, Industrial Department, Rochester Railway & Light Co., Rochester, N. Y.

ONE of the best general tests for a proper system of illumination in an auditorium is the feeling of restfulness and the absence of eye fatigue which one experiences after being in the auditorium for some time. Although ample illumination should be provided, the method by which it is distributed should not detract the attention of the audience from the program. Very conspicuous fixtures, brilliant light sources, too much or too little illumination, should not be tolerated. The best system is one in which the light is soft, well diffused and supplied from light sources that are in harmony with the decorations and architecture.

The auditorium of the Asbury Methodist Church, of Rochester, shown in the accompanying illustrations was somewhat more difficult to illuminate than the average, as the lighting fixtures had to be placed near to the direct line of vision. A system of indirect lighting was, therefore, the only kind adaptable.

The extreme dimensions of the auditorium are 96 ft. by 64 ft. Its average height is 30 ft. A considerable part of the seating capacity is under the balcony, which extends around three of the four sides. A good light is required on the platform for the preacher, organist and choir. The decorations of the auditorium are ideal for indirect illumination. The ceiling and coves are a very delicate cream; the walls

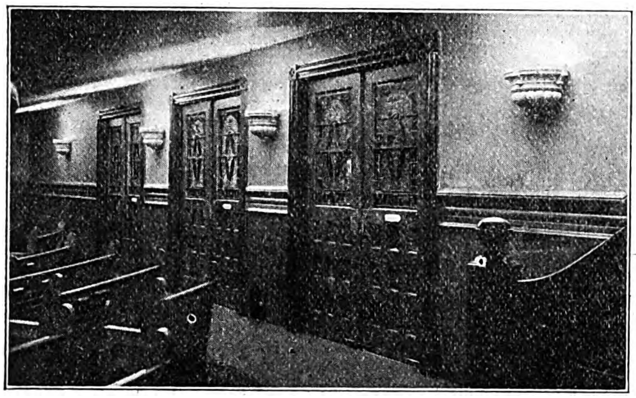

Fig. 2—Wall Urns Serving as Lighting Units at Main Entrance to Auditorium Under Balcony—Ordinary Brackets Would Cause Glare.

are colored with blended tones of brown over a coat of cream; the woodwork is natural oak and the organ is finished in dull gold. The windows are dark stained glass.

Most of the illumination is supplied by five large luminous-bowl type indirect fixtures (see Fig. 1) suspended 8 ft. below the ceiling, each containing five 200-watt Mazda type C lamps and X-ray reflectors. The art glass bottom of each fixture is dimly lighted with three 40-watt Mazda B lamps. One of these bowls is hung from the top of the central dome as a semi-direct fixture. The cross-sectional diagram (Fig. 5) shows the location of this lighting unit, as well as some of the others.

As the ceiling under the balcony is too low for ceiling fixtures, wall type fixtures were selected. The wall urns shown in Figs. 2 and 4, are 8 ft. above the floor and each contains an X-ray reflector which throws most of the light from its 100-watt lamp at an angle of 45° away from the wall. This angle was chosen, as the bulk of the illumination is required at the seats rather than in the passageway.

The platform is illuminated by four 200-watt lamps and X-ray concentrating reflectors placed in a metal box over the slot in the ceiling (see Figs. 3 and 5). The lamps are 4 ft. above the ceiling. The box is partitioned into four compartments so that the light sources can not be seen by those sitting near the front and at the sides of the auditorium. These lighting units are tilted slightly so as to increase the illumination on the organ. Those parts of the box which are visible have been painted a dull black for the elimination of glare. These units are quite inconspicuous and serve to light the platform very well.

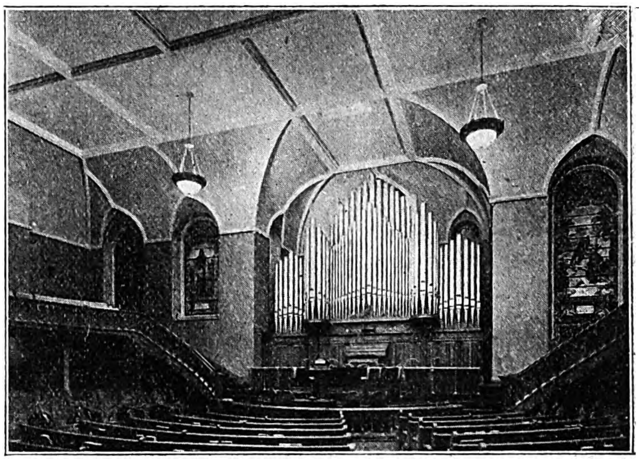

Fig. 3.—General View on Main Floor of Auditorium—Note Location of Four Light Boxes on Ceiling for Lighting Organ and Platform.

The control of the lighting units was designed to be sufficiently flexible, so that economy could be exercised in supplementing daylight with artificial illumination as needed. A small amount of general illumination is supplied by the central fixture in the dome.

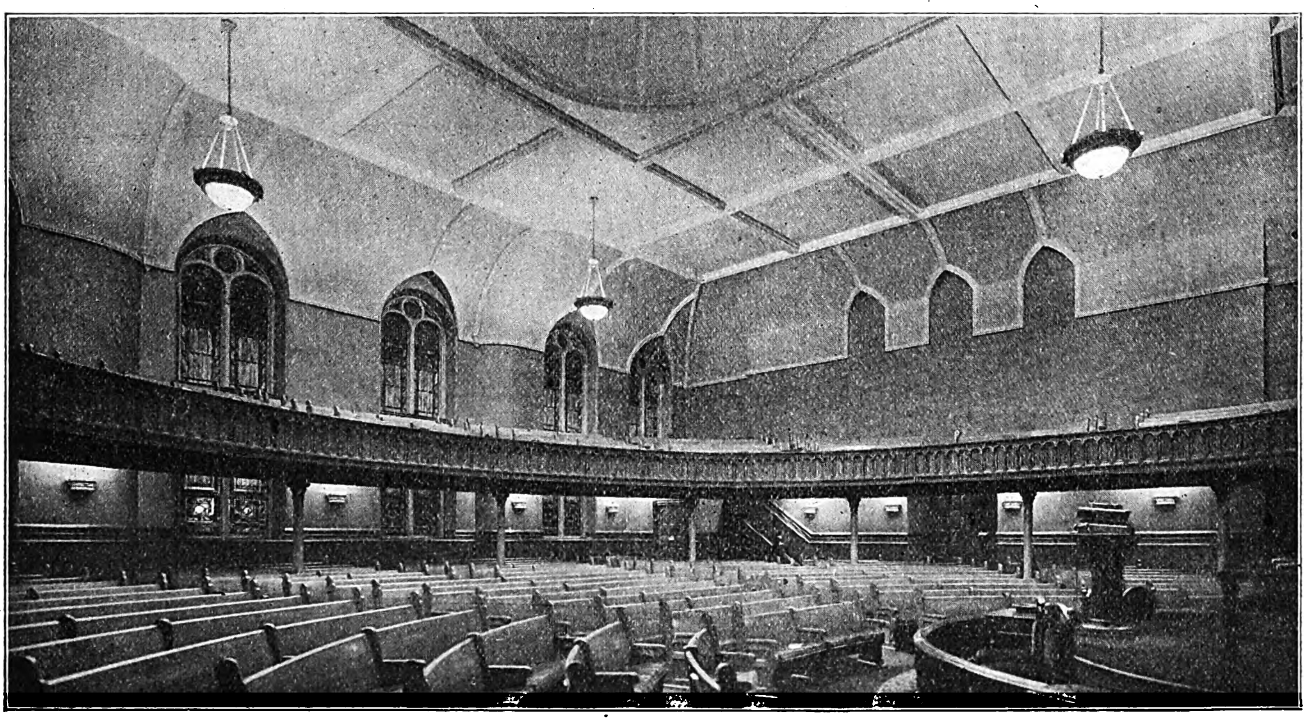

Fig. 4.—General View of the Auditorium, Showing Both Ceiling and Wall Lighting Units.

The lighting units over the platform, the two front ceiling fixtures, alternate wall urns, the three remaining ceiling fixtures, the remaining wall urns—these are turned on in the order named as the requirements for additional illumination increase with the decrease in intensity of daylight.

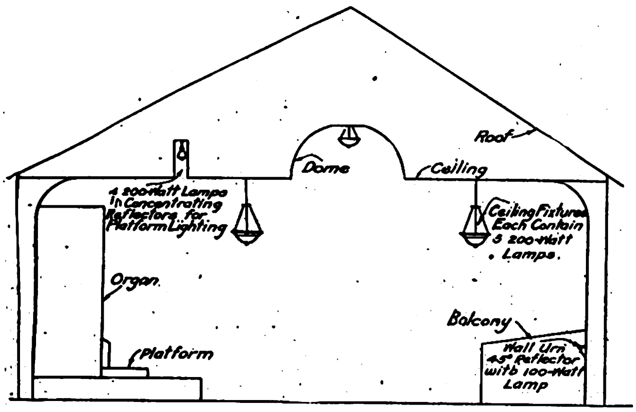

Fig. 5.—Cross Section of Asbury Methodist Church, Showing Location of Lighting Units.

Favorable comment on the new lighting of this church has been made by the congregation, by the trustees and minister, and by visitors. The illumination is very pleasing and yet efficient.

SUPPLEMENTAL STATEMENT ON ELECTRIC RAILWAYS GIVEN OUT.

Director Sam. L. Rogers, of the Bureau of Census, Department of Commerce, has issued the following supplemental statement in regard to capitalization and traffic of the electric railways in the United States. The original statement showing the growth of electric railways in this country during the past decade was published in our issue of May 31.

The total capitalization of the electric railways, street and interurban, for the year 1917 was $5,525,-025,923, representing an increase of 46.4% over 1907; and deducting investments in securities and non-operating property, the net capitalization was $4,882,764,-201, as compared with $4,243,317,727 in 1912 and $3,400,107,899 in 1907, representing an increase of 15.1% for the period 1912-1917 and of 24.8% for the period 1907-1912.

The total number of revenue passengers was 11,304,660, 462 in 1917, 9,545,554,667 in 1912, and 7,441,114,508 in 1907, representing an increase of 51.9% for the decade. The average number of revenue passengers per mile of track (based on total track mileage, including sidings) was 252,323 in 1917 and 216,522 in 1907; the average number per passenger-car mile, 5.4 in 1917 and 4.7 in 1907; and the average number per passenger-car hour, 53.7 in 1917 and 43.1 in 1907.

The detailed data are given in the following table:

ELECTRIC RAILWAY CAPITALIZATION AND TRAFFIC STATISTICS.

TRAFFIC.

	1917.	1912.	1907.	Per cent of increase.[1] 1907-1917.	1912-1917.

Interborough Rapid Transit Company's 70,000-Kw. Turbogenerator

Salient Features of Turbine—Methods of Operating Three Elements — Steam Consumption of Unit

THE Interborough Rapid Transit Co., New York, has recently placed in operation at its 74th Street Power House, a turbine that is remarkable for two reasons. In the first place, it is rated at 60,000-kw. capacity continuously, and 70,000 kw. for two hours, so it is, therefore, the most powerful prime mover in the world. Secondly, it has three elements, one high-pressure and two low-pressure, and it is the first triple cross-compound turbine to be placed in operation.

This immense machine will assist in meeting the greatly increased demand for transportation in New York City, due to the opening up of a new subway system, and the extension of the service of the existing subway, elevated and subway lines. The Interborough's power requirements have increased in the past few years with extraordinary rapidity. In 1904 the 74th Street Station contained nine reciprocating engines driving direct-current generators, each rated at 5000 kw. This amount of power sufficed for a while, and then in 1913, it became necessary to remove four of these engines and install in their place, three compound 30,000-kw. turbines. Though 90,000 kw. was thus substituted for 20,000 kw., this increase was hardly obtained when it, in turn became insufficient. Now, 70,000 kw. more is added, and probably additional units will again be needed in the not distant future.

The new unit occupies a floor space of 52 by 50 ft., and is about 19 ft. high. The high-pressure element receives steam at 205 lb. gauge pressure, and superheated 150° F., and exhausts it into the low-pressure elements at 15 lb. gauge pressure. The two low-pressure elements are identical in construction, and each receives one-half of the steam from the high-pressure element and exhausts it into the condenser where a 29-in. vacuum is maintained. All three elements operate at 1500 r.p.m., and each drives a generator rated at 20,000 kw. continuously, 23,500 kw. for two hours, and 30,000 kw. for a half hour. The generators deliver three-phase, 25-cycle, 11,000-volt alternating current.

Details of Turbines.

Though consisting of three separate elements, the entire machine is started, synchronized, and controlled

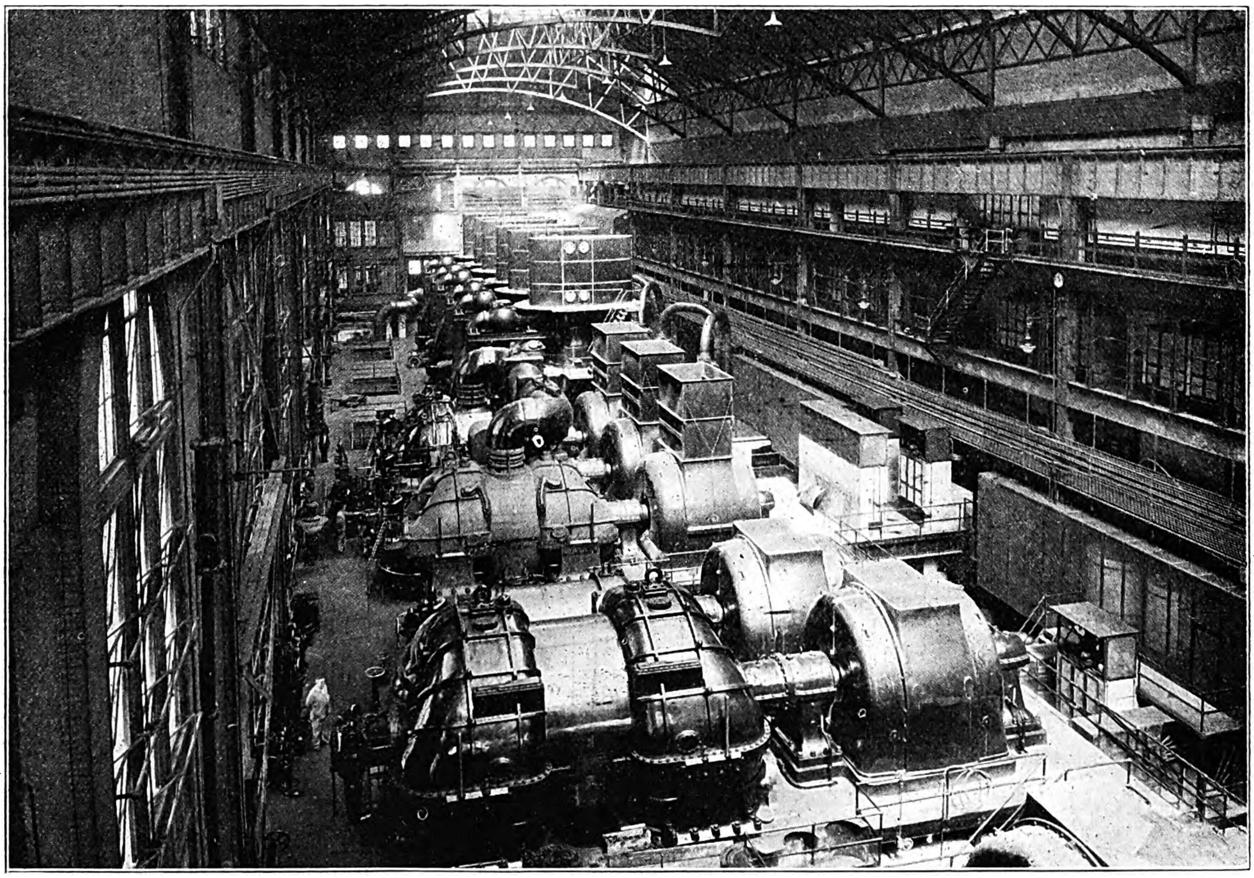

Fig. 1.—General View of Interior of Interborough Rapid Transit Power House, East 74th Street, New York, Showing One of the Westinghouse 30,000-Kw. Cross-Compound Units in Foreground, Newly Installed 70,000-Kw. Triple-Compound Unit in Center and Old 7500-Hp. Engine-Driven Units in Rear.

as a single unit. At the same time, any one or two of the elements can be shut down without interfering with the remainder, so that the high efficiency of a single large machine is combined with the flexibility of three smaller machines. In addition, the three small elements are mechanically much stronger than a single large one would be; the temperature differences in any cylinder are considerably less, and commercially common materials, with moderate blade speeds and stresses, can be used.

All of the turbines are of the pure reaction type, without the usual impulse elements, a form of construction considered preferable in view of the great volumes of steam to be handled. The high-pressure turbine is of the single-flow type, and is of cast steel. The low-pressure turbines are of the semi-double-flow type; that is, the steam enters near the center of the turbine and flows as a whole through a portion of the blading, and then divides into two portions, each of which flows through a separate section into the condenser. Since the low-pressure turbines must receive high-pressure steam in case the high-pressure turbine

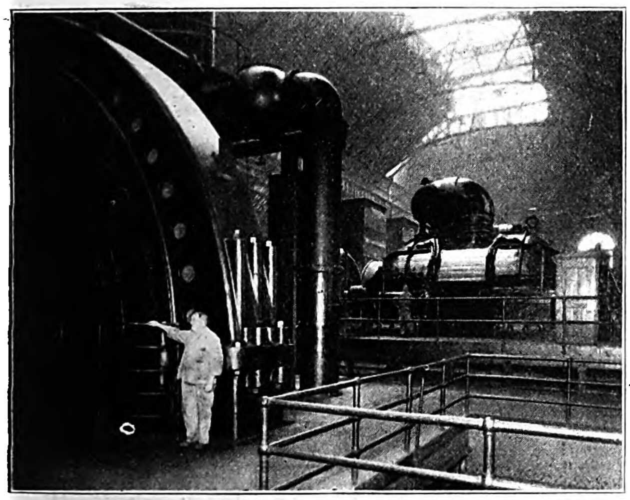

Fig. 2.—Interior of Interborough Rapid Transit Co.'s Power House, Showing Old 7500-hp. Engine-Driven Unit in Foreground and Newly Installed 70,000-kw. Turbine in Rear.

is shut down, the central portions of these turbines are made of cast steel also. All three rotors are equipped with Kingsbury thrust bearings, in order to prevent axial movement.

Features of the Generators.

The generators are so connected to the busbars that any combination of them can be operated in parallel. In practice, however, all three are brought up to speed together, and synchronized through a single oil-switch connecting the generator buses to the main bus. Reactance coils are installed between the various buses, which limit the amount of current that can flow between the generators. Should a short circuit develop in any of the feeder circuits, or a burn-out occur within a generator, the generator affected is disconnected from the buses by a circuit-breaker without interfering with the operation of the other generators.

The method of synchronizing the generators is as follows:

The field current is first applied to all of the generators, and then the throttle valve of the high pressure turbine is partly opened. As soon as the high-pressure rotor starts revolving, it will start the rotors of the low-pressure turbines through the field current. All three then come up to speed together in correct phase with each other. They are then synchronized with the system and connected to it by closing a single circuit breaker.

Operating Features of Governor.

The governing mechanism must not only control the unit as a whole, but also each turbine operating

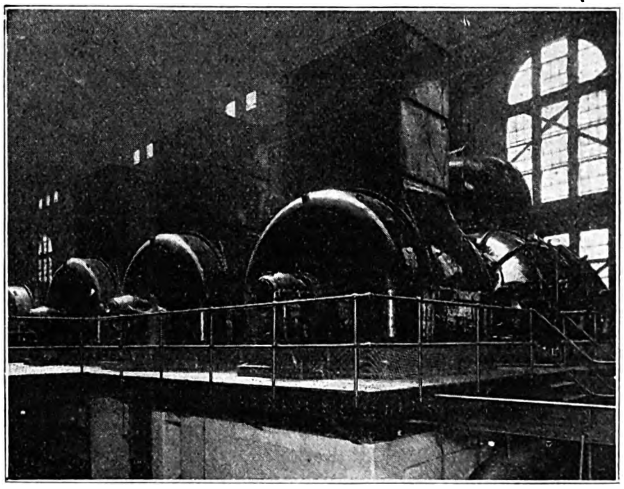

Fig. 3.—Close-Up View of 70,000-kw., Triple-Compound Turbine, Largest in the World.

separately. Some of the operations performed by the governors are as follows:

If serious electrical trouble develops on the circuit of one of the generators of the low pressure turbines, a circuit breaker will disconnect this generator from the bus bars. Relieved of load, the turbine begins to speed up, but before its speed has increased four per cent, its governor shuts off the steam supply from the high pressure turbine. This, of course, raises the back pressure of the high-pressure turbine, and a back-pressure valve opens allowing part of the exhaust from the high-pressure turbine to pass into the atmosphere, while the remainder goes into the other low-pressure turbine.

In the meantime, the first low-pressure turbine, being without steam, shuts down. When its speed reaches three per cent below normal, the governor admits high pressure steam, and the turbine continues

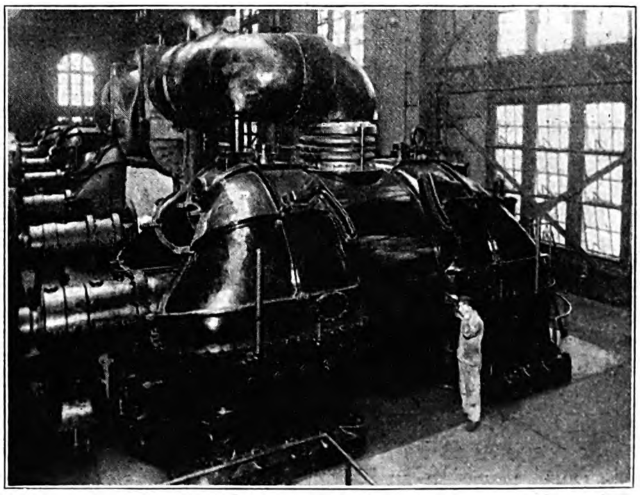

Fig. 4.—Governor and Controlling Mechanism for 70,000-kw. Turbine.

to operate at this speed until the switchboard operator either shuts it down or restores normal conditions.

Should the generator of the high-pressure turbine be cut out of the circuit, the governor cuts off practically all the steam to the entire system, leaving just a sufficient flow to maintain the speed of the high-pressure turbine now without load. The speed of the two low-pressure turbines decreases, and when the frequency drops three per cent, the governor admits high pressure steam direct to the low-pressure turbines, which then continue operating. The switchboard operator can now either restore matters to normal or shut down the high pressure turbine.

Each turbine also has an emergency stop, which will operate automatically in case the governor fails and the turbine begins to race, or it can be tripped by the switchboard operator.

When one of the turbines fails with the entire unit heavily loaded, the governors permit each of the remaining turbines to carry the maximum load of 30,000 kw. This can be maintained for a half hour, which is regarded as sufficient time to get other generators into operation, and thus relieve the overloaded turbine.

The condenser equipment consists of two 25,000 sq. ft. surface condensers for each low-pressure turbine. There are four circulating pumps, three Le Blanc air pumps, and four condensate pumps. All of these pumps are turbine driven (the air pumps directly and the others through gears), and all are so arranged that one or more can be put out of service without interfering with the operation of the condenser.

The steam consumption of the entire unit, which is a Westinghouse machine, at its point of best efficiency is 10.7 lb. per kw-hr. The high-pressure turbine and one low-pressure turbine, operating together, consume 12 lb. of steam per kw-hr.; and one low-pressure turbine alone consumes 14.25 lb. The total steam consumption at full load is 826,000 lb. per hour.

ELECTRIC STARTERS ADD TO SAFETY OF FLYING.

Description of Equipment Used on Trans-Atlantic Seaplanes.

It is not generally known that the "N. C." flying boats which accomplished the successful trans-Atlantic flight were the first heavier-than-air machines in this country to be equipped with electric self-starters for each of their big Liberty engine motors.

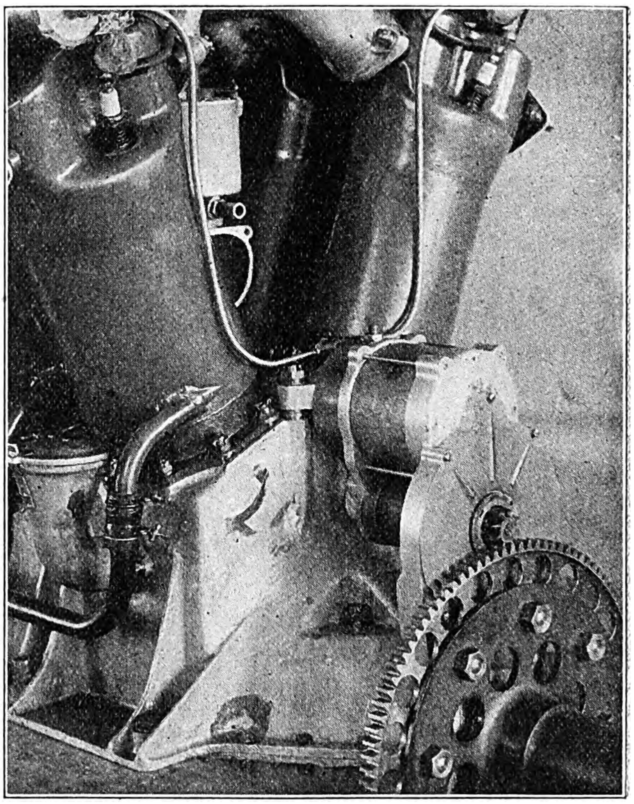
The result of the Navy Department's decision to so equip its seaplanes undoubtedly aided the success of the enterprise, for the NC-3, lost in the sea and fog near the Azores, all her engines stalled, wet and cold, would never have been able to taxi into Ponta del Gada under her own power without the assistance of mechanical means for starting her propellers.

This little device, the work of the Bijur Motor Appliance Co., of Hoboken, N. J., consists of a small 12-volt electric motor operated by a storage battery connected through a geared reduction to a Bijur automatic screw drive. On the end of the screw shaft is cut an 8-tooth pinion which meshes with a larger gear on the propeller shaft. The starter will turn over the engine at 40 to 50 r.p.m. with a consumption of 100 to 110 amperes and a maximum of 1300 ft-lb. is available on the engine crank shaft, for breaking loose a cold engine. When the engine begins firing the screw drive automatically demeshes from the crank shaft gearing. The storage battery weighs 26 lb. and has a rating of 24 ampere-hours, or sufficient to supply enough current to make 150 starts on one charging.

An interesting incident of the American trans-Atlantic flight was that all three planes carried extra propellers, intending if one should break, to descend to the water, change propellers, and start off again. They depended on the starter to make this possible.

It is also said that the C-5 (Blimp) met such strong head-winds on her trip from Montauk Point, Long Island, to New Foundland, that the force of the wind stopped her propellers, and it was necessary to ascend to a higher level to avoid them, the starter with which she was equipped starting the engines while in mid-air.

In the days before aeronautical starters were developed—which is to look back scarcely two years—it



Electric Starter on Airplane Engine.

took three men to start an airplane. One man turned over the propeller while two others, grasping him by his extended hand, stood ready to pull him away from the tremendous sucking power of the fast revolving blades.

A new aircraft engine starter, which fits on the non-driving end of the engine, has just been developed. It operates substantially the same as the propeller and starter (described above) except that the gearing is fully enclosed and the starter projects less than 5 in. from the crank case.

The starter is entirely disconnected from the engine except during the time of starting. The gears cannot be meshed while the engine is running and a safety device is provided which prevents damage in case of backfire.

Twin engine dirigibles of the "C" and "D" classes, U. S. Navy, have adopted the electric starting system. The equipment has also been in use for some time on Blimps, using Hispano-Luiza engines, and has more lately been applied to nacelles fitted with the "all-American" Union engine.

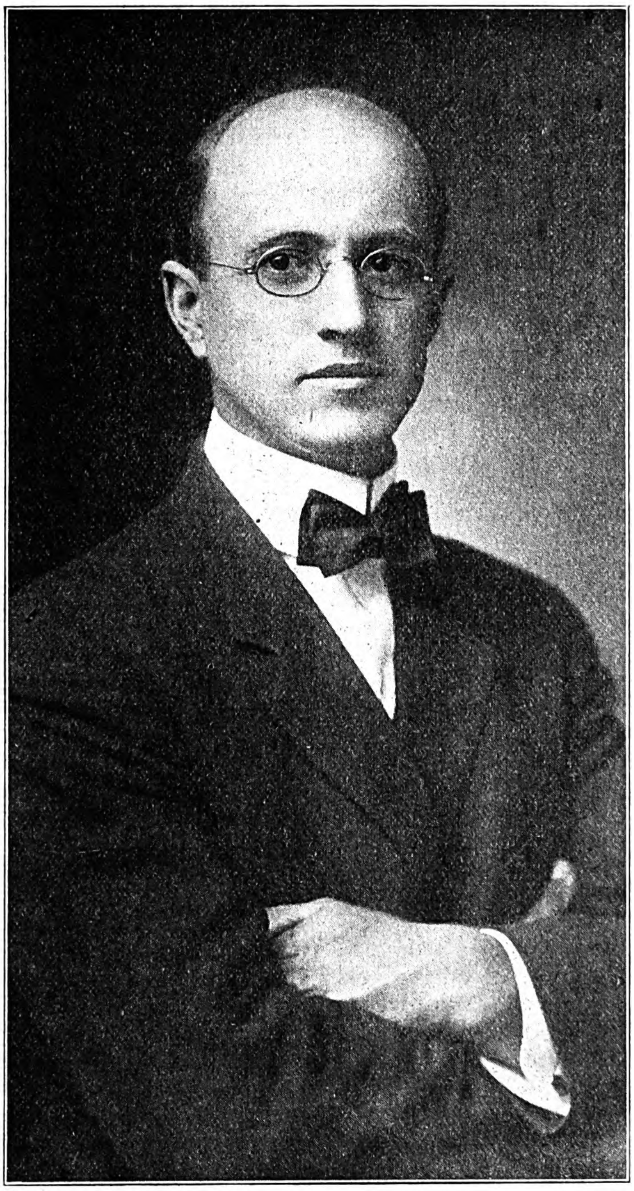
A. I. E. E. Convention at Lake Placid

President Adams' Address on Problems of the Day Makes Co-operation the Keynote—Technical Matters Receive their Due—Features of Convention

WITH a pleasing admixture of business, pleasure and relaxation, the thirty-fifth annual convention of the A. I. E. E. at Lake Placid, New York, came to a close on June 27. The program called for technical or business sessions during the mornings only, the afternoons and evenings being devoted to sports and pleasures and the relaxations that made the convention a real vacation. The program was a light one, as convention programs go, although the subjects might all be called heavy ones, serious problems of today and of tomorrow.

All the technical papers discussed problems of transmission—relay protection, the effects and benefits of grounding the neutral, effect of transient voltages, high-tension single-conductor cables for polyphase systems, dielectric field in an electric power cable, and problems of 222-kv. transmission—an arrangement that was thought to be more productive of results than a more widely diversified program. One of the outstanding features of the convention undoubtedly was the address by President Adams, excerpts of which follow and which will be found commented upon editorially on other pages.

In this issue will be found a report of the discussion on the two papers entitled "Transmission Line Relay Protection" and "Grounding the Neutral of Generating and Transmission Systems." The former of these papers appears on page 13 of this issue. The latter will be abstracted in the issue of July 12; in this same issue will be found an abstract of Mr. Silver's paper on "Problems of 220-Kv. Power Transmission," with the report of the discussions on the remaining papers and the important report of the Committee on Development.



President Comfort A. Adams.

In the opening address of the convention President Comfort A. Adams drew attention to the general unrest in all sections of the world arising out of the great war. This has led to a change in the old order of affairs. Speaking of the future he said: "Are we as engineers, educated men, who pride ourselves on our breadth of vision, who complain because we are not properly recognized in large questions affecting the public welfare, going to crawl back into our little cabins and leave the steering of the ship to those we consider incompetent, or are we going to scrutinize the ship's log to see why she ran on the rocks and then revise the sailing orders accordingly?"

With this simile Prof. Adams took up the subject of co-operation. He pointed out that the history of human society is the history of co-operation, that every commercial transaction is made on the assumption of mutual benefit to both parties concerned. "The more the mutual confidence and the co-operative spirit, the freer and the more efficient will be the interchange and the greater the mutual profit. This is merely the simplest possible illustration of co-operation to show its fundamental nature," said Professor Adams. "Industrial co-operation, from which my illustrations are drawn and with which engineers are mostly concerned, usually involves more than this simple and somewhat restricted co-operation between buyer and seller; it involves co-operation all along the line, internal and external, between producers, between consumers, and between producers and consumers.

"The obstacles to co-operation, particularly between the larger units, are of two varieties, material and human or intellectual. The chief material obstacles are space coupled with imperfect means of communication and transportation, differences in language, differences in coinage, weights and measures, and duties or tariffs. Some of these bear obviously only on international co-operation. The chief intellectual obstacles are tradition, custom, prejudice, suspicion, distrust, jealousy, narrow-minded and short-sighted selfishness or greed, or in general ignorance and lack of understanding one of the other. Most of this latter group bear upon minor or internal as well as upon international co-operation."

The Spirit of Co-operation.

Professor Adams traced the connection between engineering and industrial standardization and co-operation, showing that as a result of standardization the confusing and conflicting claims of competing salesmen are eliminated because the purchaser is placed in possession of definite knowledge of the characteristics or capacities of machines, and thus is able to select discriminately and wisely. But this co-operative spirit apparently does not always prevail. The speaker continued: "Until very recently the French national committee of the International Electrotechnical Commission contained none of the designing or manufacturing engineers, it being assumed that the latter would be biased and partisan in their attitude. As a result the manufacturers formed a syndicate with a committee and standardization rules of its own, which were and even now are to some extent the rules generally employed in France, although much inferior to our own. In some cases the American rules are specified. Even now the French rules originate in the manufacturers' syndicate and are passed on to the French national committee for its approval with a consequent loss of time and efficiency.

"As the work of our own standards committee expanded we found it overlapping the work of other societies in adjacent fields, and co-operative relations were established. This failed from the lack of any suitable and generally acceptable co-operative machinery. A movement was then started by the Institute, more than two years ago, to organize a central body (the American Engineering Standards Committee) to co-ordinate all the work of engineering standardization being done by the various engineering organizations. The objects of this organization are to avoid overlapping, duplication of effort and the confusion of conflicting standards; to insure the employment of an effective and sound procedure in the development of standards, to the end that a standard when promulgated may be not only workable but also acceptable to all concerned and the only accepted standard of its kind; to stimulate desirable standardization and at the same time to shut off premature or ill-advised attempts at standardization.

"The consummation of these objects will mean an enormous saving of effort in the production of standards, a tremendous increase in the value and usefulness of standards, and, when the work is brought up to the needs of the time, an incalculable saving in the cost of production and the productivity of labor. International standardization will be a tremendous stimulus to foreign commerce; but such international standardization is in most cases exceedingly difficult without a central authoritative body with which similar foreign bodies may co-operate. Several instances of this difficulty which have actually arisen during the past two years could be cited. These have resulted in hopeless confusion, misunderstandings and waste of time and money.

"Great Britain has its Engineering Standards Association, which during its eighteen years of life has demonstrated its reason for existence and its value to industry and to the government. The work in air craft standards alone which it is doing on behalf of the government involves some fifty odd sub-committees. France now has its permanent Standards Commission, a little more than a year old, and just getting under way. Holland also has its Normalization Bureau for the same purpose, and Switzerland is just starting a movement in this direction.

"With all these national bodies our American Standards Committee has already established cordial co-operative relations. The American Engineering Standards Committee, although organized last October, is now in process of reorganization; but the success of any such movement is in direct proportion to the degree in which the co-operative spirit prevails. It is the fear rather than the fact that causes the trouble. Even if the sacrifice were much more than it is, however, the price would be small in proportion to the result.

"It is the generous co-operative spirit for which I am pleading, rather than the timid spirit of him whose vision is of such short range that he dare not take a man's size step for fear of stubbing his toe, who holds the little present so close to his eye that it shuts out the whole landscape of the future, whose immediate self-interest or small-group interest is so dominant as to hide anything beyond.

Industrial Research.

"Another fertile but as yet little cultivated field for co-operation," Prof. Adams went on to say, "is that of industrial research. Here we have a field where the obstacles of the second group are specially dominant—particularly short-sighted self-interest and corporate interest and the timid desire for secrecy. That many of the most important and revolutionary developments of modern industry are dependent upon research needs no proof. It is not so obvious to many, however, that co-operation in industrial research is to any large extent feasible at the present time.

"After some experience in this field I am convinced that thorough-going co-operation in industrial research would mean not only a reduction of the cost of research to a small fraction of its present figure, a much more rapid industrial development of the country as a whole and a material increase in the productivity of labor, but also an increase in the profits of every intelligent party to the co-operation.

"Serious co-operation of any kind between widely separated groups is practically impossible without the mechanism of transportation and communication provided by the work of the engineer. Also, with this mechanism developed even to its present degree of perfection, co-operation becomes not only possible but also desirable and necessary, even between comparatively widely separated groups. Moreover, the problems which confront the world at this time are largely a direct result of this mechanism. Are we as engineers going to leave their solution to others? Are we going to be satisfied to play alone in our own little backyard and never look around us even after most of the fences have been removed by our own work? Are we going to fail to take an interest in our neighbor who has much that we need, from whom we have much to learn, and by co-operation with whom we can profit broadly? If we do offer co-operation, is it to be with the provision that we gain all and sacrifice nothing? Are we going to be satisfied to sit back and criticise destructively the details of a co-operative agreement, priding ourselves on our critical faculty, however valuable that may be at times, when the real basis of the criticism is either intellectual pride or short-sighted fear that we, as individuals or as a group, may lose a little of our independence or prestige; when the issue at stake is in some cases of such paramount importance even to us as individuals—had we only the vision to see it—as to overshadow our very existence?

"Let us rather make use of the logical habits of thought and freedom from bias which at least should be the result of our training and take our part in the solution of the problems we have helped to create. Let us see the goal ahead and start for it without thought of fear or favor, as sure-footedly as possible, but with that generous co-operative spirit which will surmount many an apparently impossible barrier, critical of details if so minded, but generously and constructively so."

Monopolies of Labor and Capital.

Professor Adams then dwelt upon the serious problems arising from the worldwide unrest in the labor group in the following words: "It is very easy to criticise and condemn this attitude because of its unreasonableness, looking down from our superior height of intelligence. It is very easy to assume that it is merely a matter of showing the laborer the error of his ways and of forcing him into line. But would it not be wiser at this time to examine our own attitude with equal care, to make sure that we are setting an example which if followed by labor would solve the problem? Is demanding 'all the traffic will bear' under the pressure of organized labor any worse than the same policy carried out by the capitalist whenever he has the monopoly grip? Unfortunately the two cases are not treated the same by our laws. Labor monopoly is not subject to the same limitations and responsibilities as is capital monopoly. That disparity should be removed. But there are two forms of monopoly other than of labor which are not only not limited by but are actually fostered and protected by our laws, and in which the only limitation ever dreamed of by the owner is 'all the traffic will bear.' These are patents and titles to land."

Professor Adams then explained at length these monopolies showing that it was incumbent on the engineer to assist in a progressive rational evolution of society rather than encouraging and inducing a revolution by a reactionary policy.

The Duty of the Engineer as a Citizen.

"Are we sincere in our desire to be more recognized in our broader capacity as citizens and to be consulted in matters of broad public interest if we are not sufficiently interested in those matters to make an intelligent study of them, if we are satisfied to accept without analysis the prejudices and propaganda of a biased group, however intellectually superior that group may consider itself, if we cease to utilize our logical habits of thought, our habit of analysis, of demanding the reason why, as soon as we step outside of the realm of those physical laws which force us to think straight? Are there no laws in this other realm of human relations which are just as inexorable as the physical laws with which we are so familiar? Is there no law of compensation which is the counterpart of our law of conservation of energy? Are we going to be allowed to go unpunished for crooked or careless thinking in this other realm any more than in the purely physical realm?

"What can we expect of labor in the way of intelligent fair-mindedness if we, with our superior advantages, encourage the perpetuation of institutions which work for serious injustice to the many for the benefit of the few, or even if we allow them to persist because of our lack of intelligent fair-mindedness?

"My opinion as to the seriousness of the present world situation, as to the importance of the problem before us, is not mine alone but that of many thinking men in this country and in others. I have talked with many influential men in France and England and have found a striking unanimity on this point.

"May we not as engineers utilize our training and experience, our method of thought of which we are so proud, to encourage clean, straight, unbiased and fair-minded thinking, and to encourage that broad, generous co-operative spirit which will mean so much in breaking down the barriers which separate classes within a nation, as well as the nations themselves, and which is essential to the solution of the world problem which is knocking so hard at our door?"

Discussion at Tuesday Morning Technical Session.

In responding to President Adams' introduction, the president-elect, Calvert Townley, expressed his appreciation of the honor conferred on him and especially of the opportunity for leadership. He contended that engineers should be just as able to be prominent in the public eye during peace times as they have been during the last few years in helping to carry the war to a successful conclusion. He could not see any far-reaching danger in the present labor agitation because he declared that any body which seeks to secure more benefits than are due it cannot succeed.

The first paper of Tuesday morning's session was presented by H. R. Woodrow, D. W. Roper, O. C. Traver and P. MacGahan on "Present-Day Practice of Transmission and Tie-Line Protection," an abstract of which appears elsewhere in this issue.

Two papers on grounding the neutral were presented at this session—one by H. R. Woodrow and the other by William E. Richards. In his paper, Mr. Woodrow said that experience had unquestionably shown that cable stresses are considerably relieved by grounding the neutral. Further, it is believed to be desirable to limit the ground current as much as possible, thereby reducing the stresses on the system, and particularly the burning of the lead sheath and grounding connections. The installation of grounding relays, set to disconnect a feeder more quickly than the straight normal-current relays, will further greatly relieve the potential stresses resulting from prolonged grounding current which occur even with a grounded system.

Mr. Richards in his paper said considerable improvement in operation has been observed since changing from an ungrounded system to a directly grounded Y system in Toledo, where about 16,000 kw. is transmitted over 23,000-volt, 25-cycle transmission circuits connected with underground cable.

The papers presented at the Tuesday morning session were on relay protection and grounding of the neutral and the discussion of these papers was taken up at the same time. The following were among those taking part in the discussion: Philip Torchio and H. R. Woodrow, New York Edison Co.; D. W.

Roper, R. F. Schuchardt, Commonwealth Edison Co.; H. C. Albrecht, Philadelphia Electric Co.; A. H. Lawton, Consumers' Power Co.; J. A. Johnson, E. A. MacKenzie, Don Carlos, Ontario Power Co.; F. L. Hunt, Turners Falls Power & Electric Co.; P. H. Adams, N. L. Pollard, Public Service Electric Co.; W. de L. Carr, United Gas Improvement Co.; R. R. Honaman, Bureau of Standards; A. E. Silver, Electric Bond & Share Co.; E. T. Moore, Halcomb Steel Co.; J. C. Parker, University of Michigan; H. B. Vincent, Day & Zimmerman; Chas. Proteus Steinmetz, J. R. Craighead, E. F. Creighton, E. G. Merrick, of the General Electric Co.; P. M. Lincoln, F. D. Newberry, F. C. Hanker of the Westinghouse Electric & Manufacturing Co.

Discussion on Relay Practice.

Terminology used in connection with relay practice received considerable discussion, some of the speakers even objecting to the classification of devices given by the protective devices committee.

J. R. Craighead declared that the future practice in designing or extending transmission lines should take into consideration the principles of protection as well as economy. Furthermore, increase in speed of operation of oil switches has required a corresponding improvement in relays. By so doing he believes it will be possible to reduce the time differential of delays below the ¾ sec. now believed to be the minimum. One of the greatest opportunities for improvement will be through the thorough understanding of operating conditions by actual measurements of current, etc.

J. A. Johnson expressed the belief that improvement could be made on combined use of under-voltage and over-current relays by letting the under-voltage relay control the current supplied to the tripping bus. This scheme has been successfully used at Niagara Falls in the generator neutral. Greater improvement in circuit breakers will have to be looked to in the future for isolating cable faults.

Mr. Albrecht said the cycle counter is used extensively at Philadelphia for setting and checking relays. A differential of 25 cycles is allowed for relays, 15 cycles for the oil switch to operate and 10 cycles for inaccuracy of relays. It was his opinion that it is impracticable and expensive to test on the primary side of current transformers as suggested in Mr. Woodrow's paper declaring that too much emphasis is placed on the reduction in busbar voltage during short circuits.

P. Torchio admired the ideal to which Mr. Johnson aimed, namely, a circuit breaker which would open any short circuit, but said it is too far in the future. The better way to do, in his opinion, is to reduce the amount of power that can go into a short circuit in order that the selective relays can be properly applied. He contended that it is better to follow this American development than to change to European practice.

P. M. Lincoln pointed out that the possibility of interruption of service is increasing with the increase in size of electric service systems, while there comes a greater need of reliable service. Hence there is vital need at this time and in the future for considerable investigation of the protection of large systems in order to offset these contending factors. In this connection it is encouraging to note that the efficacy of grounded neutrals is fairly well demonstrated, companies in Toledo, New York and Montana having reported favorably.

Dr. Steinmetz said the problem of relay protection is the production of simple, reliable and automatic apparatus that will permit an abnormal circuit, cable or piece of apparatus to be disconnected without interfering with the operation of any normal line or cable. When disturbances occur, normal circuits as well as the circuits in which the disturbance takes place are affected, so that devices that indicate or act merely when abnormal conditions take place will not solve the problem because the conditions require a device whose operation depends on the magnitude of the abnormality.

R. F. Schuchardt stated that engineers have been slow to recognize that relays reduce investment expense, due to the saving possible through interconnection. Now, he contended, it is very largely a case of providing the proper talent to maintain relays in order that the manufacturers may know where further improvement may be made. He suggested that the protective devices committee serve throughout the coming year as a clearing house on experiences with relays to permit an interchange of information on this subject. Chicago probably has a larger system in a limited territory than probably any other company; the conditions met there may be the same as those of other systems in the near future, so their problems and solutions are worthy of considerable study by such companies. On this system the circuits are sectionalized by reactors to limit the power which can be supplied to any fault. In each section one unit is grounded through a 2½-ohm resistance.

Don Carlos queried the need of so small a total time interval as two seconds in relay setting. The Ontario Power Co.'s system allows a total interval of eight seconds, while on an associated system four seconds is maintained without trouble, owing to the long time setting. It would be impossible to maintain the setting of ¾ sec. between relays with satisfactory results, he said, at least double that time being necessary with the equipment in use.

E. P. MacKenzie said that automobile batteries of both the lead and Edison types have been used for operating relays by the Ontario Power Co. The lead type appears to be more economical for this particular purpose, although dry cells are still more so. The latter are being used by some companies even for 110-volt oil-switch control. He recommended the method of Mr. Johnson of using under-voltage relays to control the tripping bus in conjunction with over-current relays, a master relay being employed for a similar purpose on the Ontario system with satisfactory results. For generator protection Mr. MacKenzie advocated definite-time relays. He does not consider it necessary to set relays from the primary side of the transformer but recommends testing them after each automatic operation for characteristics, including minimum current required to operate them.

E. G. Merrick considered it hardly necessary to reduce the total operating time of relays and switches below .2 sec. to protect generators and transformers as they can withstand short circuits for this period of time. On the Montana Power Co.'s system higher reliability of relay operation has been obtained by grounding neutrals, about the only trouble now experienced being on account of the high resistance of grounds.

D. W. Roper said that tests conducted by the Commonwealth Edison Co. show that if relay action is not very rapid, synchronous apparatus will be thrown out of step when a short circuit occurs very near the equipment. However, if the short circuit occurs some distance away, increasing the reactance and resistance of the circuit thereby, this trouble will not be so acute if the relays and switches operate properly. Since the effect of burn-outs in cables and the spreading of damage is more severe when a time element is introduced into relays, it is vitally important that rapid relay action be obtained.

P. H. Adams believed a total time interval of 2 sec. might be satisfactory to maintain in relay settings for short-circuit conditions, but it might be shorter for mere overload conditions.

F. L. Hunt, Turners Falls Power & Electric Co.; A. E. Silver, Electric Bond & Share Co.; N. L. Pollard, Public Service Electric Co., New Jersey, all corroborated the benefit resulting from the grounded neutral.

J. C. Parker said that relay application should not be considered so much from the viewpoint of protection of apparatus as from that of insuring continuity of service. If this distribution is made, the problem of determining time settings is considerably simplified. Engineers too often fail to recognize that the ultimate object of central stations is to give continuous service. Mr. Parker cited one instance in which a company lost about $500,000 in revenue from two consumers through failure to eliminate interruptions. This loss is sufficient to justify considerable investment on relays.

E. F. Creighton, in closing the discussion, pointed out that balanced relays sometimes trip when circuits are being synchronized owing to the switch blades failing to make contact simultaneously. While the arcing ground suppressor was very effective when used on radial systems, it is not at all satisfactory now on parallel feeders.

H. R. Woodrow closed the discussion on relay protection and grounding neutrals by answering comments made during the discussion. He emphasized the fact that the time interval between relays depends on several factors, including relay characteristics, time required for switch operation, and nature of the system of which the apparatus is employed. While some oil switches have a speed of operation as high as 1/4 to 1/2 sec., others are slower, hence the time interval of 3/4 sec. is not so far wrong. Until high-speed breakers are developed there is no way of reducing the time interval near the generators, although this would be desirable. It may be possible to reduce the total time interval below 2 sec. on large systems, although on smaller systems a long interval is permissible. Referring to the possibility of synchronous apparatus falling out of step, Mr. Woodrow pointed out that there will be less tendency to fall back into step again if the time interval is increased. Comparing single-turn and multiple-turn current transformers, it was pointed out that the former are very accurate on overloads, but that the accuracy depends greatly on the secondary load, which may cause the speed to range from 1/2 to 3/4 sec. For this reason it is advisable to use the primary-test method recommended instead of applying current directly to the relay terminals. The next best method, so far as accuracy of results is concerned, is to apply the test on the secondary terminals of the current transformer. It is not essential to test beyond the flat part of the relay characteristic curve, in Mr. Woodrow's opinion. Unless current is limited considerably by reactors, Mr. Woodrow believes 8 sec. is too long for the total time interval because all apparatus will not withstand full short-circuit current without injury. In addition to using short-circuit protective relays, the company with which Mr. Woodrow is connected employs ground relays to clear faults before they develop into short circuits.

Technical Committees Make Their Reports.

Notwithstanding the stress of the last year resulting from the war, the technical committees were able to collect a large amount of information and important data. The reports of these committees are abstracted as follows:

Power Stations Committee Reports.—Philip Torchio, chairman, advocated changes that would tend to improve the character of the papers and their discussions. He suggested that each committee discuss the papers before they are submitted to the membership; committees should put them into best form, revise them and endeavor to have them presented at general meetings. Committees should encourage and plan discussion and the work of many of the committees might be made broader and even overlap into the work of other committees and the work even of other engineering societies. For future work a paper outlining statistical data essential to recording power-plant efficiency was proposed, relative merits of shunt and compound-wound exciters, steam and motor-driven units, etc., also are to be taken up.

Comfort A. Adams emphasized Mr. Torchio's remarks, laying special emphasis upon the benefit that will accompany closer co-operation with authors in presenting accurate, suitable and concise papers. Prof. Slichter, Columbia University, mentioned that future national meetings will be more dignified than preceding meetings, hence great care in the selection of papers will be more imperative than ever.

Committee on Telegraphy and Telephony.—Some of the many developments and improvements made during the war were reviewed by Donald McNicol, chairman. Much improvement was made in apparatus for protecting telegraph and telephone lines against lightning. Closer co-operation between power companies and telegraph and telephone companies was coming about, thus assisting to reduce inductive interference between the heavy and the small-current circuits. The vacuum-tube amplifier has been highly developed and is today the preferable form of amplifier for long-distance telephone transmission.

Committee on Instruments and Measurements.—S. G. Rhodes, chairman, told of the activities of this committee in connection with the War Department and the Bureau of Standards, in which much assistance was given toward standardizing the specifications for purchasing electrical instruments. Improvements of thermocouples for accurate measurements of alternating currents at any frequency was dealt upon, these thermocouples being superior to any German couples on the market at the time the war began.

Committee on Industrial and Domestic Power.—During the year each of the various committees on application of electricity to machine tools, the cement industry, motor characteristics, to the textile industry, etc., confined and concentrated its efforts to its specialized branch. Chairman H. G. Pierce recommended that the personnel of the committee be retained intact and the work now underway be continued. The work of these committees in the printing, elevator and machine-tool applications was reviewed.

Committee on Electrophysics.—F. W. Peek, Jr., chairman, outlined the aims of his committee as being to encourage papers of a high technical standard dealing with advances in electrophysics; to have at least one broad general paper dealing with modern physics, but free from mathematics; and the promotion of closer co-operation and mutual understanding between the physicist and the engineer. The need for keeping engineers in closer touch with the work of the physicists was emphasized.

Committee on Lighting and Illumination.—This report touched upon the demands created by the war and what tendencies are to be expected now the war is over. Considerable activity in street lighting is to be looked for now that war-time restrictions have been removed. Developments in street lighting and the application of some form of prismatic reflector for incandescent street illumination was mentioned. Some of the achievements in lighting during the war were reviewed, including the perfection of the Lynn searchlight for military and naval purposes.

Marine Committee.—The enormous activity in marine matters necessitated subdividing the Marine Committee into sub-committees known as ship installation and electric ship propulsion committee, respectively. The former has been again divided into lighting, power apparatus and distribution committees. A number of matters taken up by the power apparatus and lighting sub-committees and not considered by the main committee were reviewed and proved to be of interest.

Committee on Iron and Steel Industry.—The iron and steel industry absorbs the largest amount of electrical energy of any one industry, the motor equipment alone requiring 650,000 kw. in generator capacity to care for it, while electric furnaces are absorbing 900,000 kw. There is great need for and enormous possibilities in standardization of electrical apparatus employed in the iron and steel industry, states Eugene Frielaender, chairman of the committee. He advocates much closer co-operation with the Association of Iron and Steel Electrical Engineers and advocated that the A. I. E. E. go much farther than it has done so far toward standardizing the mechanical dimensions of pulleys, shafts, gears, etc.

Committee on Electrochemistry and Electrometallurgy.—In submitting his report, Chairman Carl Hering advocates that papers dealing entirely with matters electrical such as regulation, power-factor, etc., be delivered either before the A. I E. E. or, better still, before joint meetings of the A. E. S. and the A. I. E. E. Co-operation between the two societies is the keynote of this report.

Committee on Protective Devices.—D. W. Roper, chairman, recommends that the following phases of relay protection, oil circuit-breakers, grounding the neutral, lightning arresters, current transformers and potential transformers be investigated from the aspect of protection. Developments and improvements depend very largely upon the operating companies whose experiences enable new or modified apparatus to be evolved to meet new problems as they arise. The paper, entitled "Transmission Line Relay Protection" (appearing in abstract elsewhere in this issue), represents a large part of the work of this committee.

Committee on Transmission and Distribution.—This report, presented by E. B. Meyer, chairman, showed the committee had been very active during the year in tackling the problems of insulators and underground construction. A number of papers have been delivered on allied subjects. It is advocated that depreciation be given more consideration in reducing insulator failures and service interruptions. The tendency is to go to higher voltages. Research work in connection with dielectric losses in subteranean cables, standardized test methods and the compilation of data on operating temperatures of underground conductors are some of the matters brought up.

Committee on Use of Electricity in Mines.—As a result of this committee's activities, several papers on matters pertaining to mining have been presented before the society. The report recommends closer co-operation between the various technical national and local engineering societies.

DUQUESNE LIGHT CO. REDUCES RATES FOR RESIDENTIAL SERVICE.

New Schedule of Pittsburgh Central Station Company Based on Maximum Demand Charge.

Effective July 1, the Duquesne Light Co has placed a new schedule of reduced rates for residential electric service into effect. The new charge is at the rate of 8 cents per kw-hr. for the first 30 hours' use of the customer's demand; for the next 60 hours, 6 cents per kw-hr., and for all consumption in excess, 3 cents per kw-hr.

The customer's demand in the new rate is based on the number of lamp outlets, the first 10-lamp outlets being rated at 30 watts each, the next 20 at 20 watts each, and all in excess at 10 watts each. The company will still maintain its fixed service charge, which provides for a rate of 15 cents per month graded to 5 cents for apartment houses, hotels, etc. The minimum fixed service charge is 65 cents per month, with a rate of 6 cents per kw-hr. and discount of 1% per kw-hr. for prompt payment of bills. Local electric companies in the retail branch of the trade are using the reduced rates as an incentive to consumers to purchase electrical appliances of different kinds with considerable success.

BALL BEARINGS FOR CONSERVING ENERGY.

Introduction of This Equipment for Power Plant Use During War Proves Successful.

When the coal shortage became acute last year, central stations and others set about reducing needless wastes of energy that were small individually but represented quite a large total when taken in the aggregate. Apparatus was operated so that the most efficient units were kept in service as long as possible, apparatus not actually used was taken out of service so as to reduce core losses, which react back to the coal pile. Needless friction was eliminated wherever possible.

In reducing friction in power plants one of the practices that came was that of employing ball bearings in places where they had previously been considered ill-adapted. Even in places such as the boiler room—proverbially dirty and grit and dust laden—ball bearings have been used for shaft and stoker drive. Tests made of the relative friction losses of a 3-hp. induction motor with ball bearings, waste-packed bearings and ring-oiler bearings showed efficiencies respectively of 84, 80.5 and 81.5%. An efficiency difference of 2.5% in favor of the ball bearings becomes a matter of importance where a machine operates continuously for a high portion of the year and where there are many machines.

Transmission Line Relay Protection

Review of Typical Applications of Current and Directional Relays—Excerpts from American Institute Paper

By D. W. ROPER, H. R. WOODROW, O. C. TRAVER and P. Mac GAHAN

THERE was a time when the protection of an electrical tranmission system with the single generating station and its radial feeders was not a matter of very grave importance. That time, however, has passed and the multiplicity of generating stations with tie lines and parallel feeders have greatly complicated the once simple problem. Furthermore the practice of interconnecting large transmission systems has brought about conditions which require very serious consideration when laying out a protective relay scheme. An effective sectionalizing relay scheme is necessary in order to secure both continuity of service and maximum efficiency of transmission, and the most complicated system can be effectively relayed if all the conditions are thoroughly analyzed and proper relays, carefully set for both time and current values, are applied.

Most of the large systems of the present day have grown out of a comparatively small beginning, stations and lines being added as required, without taking into consideration the relay problem. As a consequence this problem has, in a great many cases, become rather difficult and it has become evident that the application of protective relays for sectionalizing trouble is one of the principal features to be considered in determining the design of a transmission system. This point should be borne in mind whether additions are being made to an existing system or whether an entirely new system is being designed. Numerous instances could be given, if space permitted. whereby a slightly different design in extending lines and adding stations would have given a much more simple and effective protective scheme.

The same argument applies to the design of an entirely new system, particularly if it is likely to become very complex, and in so far as practical, possible extension should be considered in the original layout so that various methods of protection can be studied and their advantages weighed against possible disadvantages of a design to which they can be applied. It will be found in practically every case that one of the many sectionalizing schemes now in use can be combined with a proper layout of stations, transmission and tie lines to give proper selective action. Thus the many difficulties encountered when attempting to apply relays to a system laid out without regard for its protection may be avoided. It is therefore of paramount importance that the selective features of various types of relays be thoroughly analyzed before adapting them to any particular system.

The most perfect relay system cannot be expected to give the best results unless the man in charge of its installation and operation be thoroughly competent and familiar with the various precautions to be taken. It is absolutely essential that he know the characteristics and peculiarities of the relays as well as the scheme he is using. Results of experience have shown that an experienced man will secure more satisfactory results from an inferior type of relay than a less capable man can secure from the best equipment obtainable.

One of the principal factors controlling the settings of relays is the amount of short-circuit current available under various conditions as outlined later in this paper.

The proper type of relays to be selected for protecting transmission lines is dependent upon whether the system is operated radially, in parallel by groups, or in loop, and the time allowable for holding a short circuit on the system. In general, however, the most simple form of relay protection where several parallel feeders are involved is the straight inverse-time current relays which are set to give times of operation which are progressively longer as the source of power is approached. In some cases, however, where an extended system is considered, the time requirements for the relays approaching the generating station are so long that it is considered dangerous or inadvisable to hold short circuit currents on for this period. We believe a delay of two seconds to be the extreme time a dead short circuit should be allowed to remain on a system, except under very unusual conditions.

The introduction of directional relays at points where power is feeding into a station will materially reduce this maximum time setting as these relays can be given a short time setting as outlined later under the heading, "Typical Applications of Current and Directional Relays."

Another method of shortening this time is by the use of the balanced system, in which case current can only flow through the relay at time of short circuit as outlined later under the heading "Balanced Protection Schemes."

Another method has been developed for shortening this time by the combination of an under-voltage relay with the inverse time current relay, as outlined later under "Combination of Under-voltage and Overcurrent Relays for Protecting Tranmission Lines."

For relay protection on tie lines, between generating stations in general, the conditions are somewhat similar to the straight transmission line relay protection if the additional precautions are taken to prevent operation on heavy momentary surges of power that are likely to exist between two or more generating stations at time of synchronizing or momentary disturbances on the system. The relay desired here is dependent to a large extent upon the method of system operation, as in some cases an operating company will want the tie lines to open, in case of trouble on a portion of the system, whereas other companies want these tie lines held rigidly in service in all cases excepting in case of trouble on tie lines themselves. In the first case shorter time settings are given to the relays and the application of straight inverse time current relays with the possible application of directional relays, is all that is required. In the second case. however, application of some form of a balanced relay. as described later, may become necessary. If the tie lines are not to stay in indefinitely, inverse-time current and directional relays with long time settings would give a very suitable operation and allow the tie lines to open in case of more serious trouble on either side of the system.

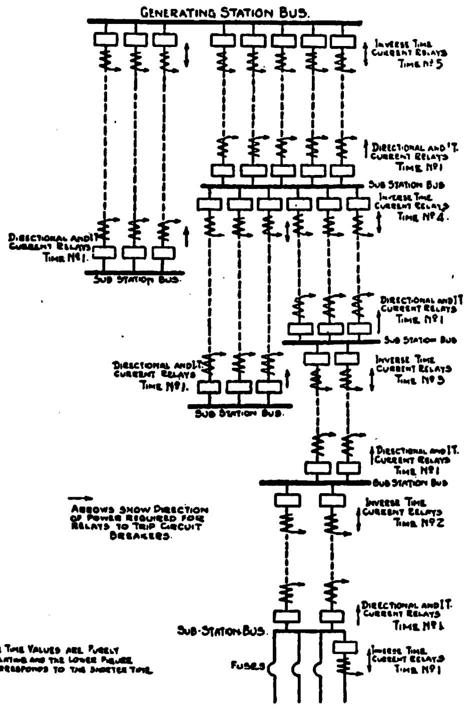


Fig. 1.—Inverse Time Current and Directional Relays as Applied to Parallel Feeders.

Some companies have connected their control and tripping circuits to the excitation bus, thereby obtaining the advantages of direct current, but sometimes this has led to considerable trouble due to the unstable conditions of this source, especially under alternating-current short circuits. It has resulted occasionally in a complete disabling of the control system on account of abnormally high induced voltages on the excitation bus with single-phase short circuits on the alternating-current generators. Great precaution should be taken against these conditions and for best results we feel that an auxiliary supply should be used if possible for obtaining at all times a constant power for the tripping circuits.

Typical Application of Current and Directional Relays.

The combination of inverse time current relays with directional relays is becoming very extensively used in cases of parallel operation of lines or of feeders forming a ring system.

Some of the trouble which was experienced in the early days was mainly due to the difficulty in obtaining a directional relay which would operate correctly under all conditions of faults, especially where low voltage was encountered. The directional relays produced at the present time are apparently giving very satisfactory results, even under low voltage conditions down to 1% of normal, and may be applied to loop or parallel group systems in series, in combination with inverse time current relays, if a careful analysis is made of the proposed installation.

For the protection of parallel groups in series, the relays are applied as shown in Fig. 1, with inverse-time current relays placed at the transmitting end and directional relays (combined with an inverse-time current element) at the receiving end. The directional relays are connected to close their contacts for power flowing from the bus to the line, and these contacts are placed in series with those of the inverse-time current relays of the same circuit so that the circuit-breaker is tripped only in case of power flowing in the direction away from the bus and of a magnitude exceeding a certain given amount for a certain time. Any time delay required is provided by the adjustments of the inverse-time current relay element.

For protecting the loop system both the inverse-time current and directional relays (with inverse-time current element) are used, as shown in Fig. 2. Each line, at each station, is provided with inverse-time current relays. Where these inverse-time current relays are given the lower time settings, directional relays are also used with the tripping contacts connected in series, so that both relays must operate before the circuit-breaker is tripped.

Reference to the time settings given in the diagram (purely relative) will show that they are graded on the same basis as a single series of tandem-connected substations, assuming that one end of the loop is open at the generator bus, and neglecting those breakers which would be incoming at the various substations. It should be noted that when the other end of the loop is considered open, the substation breakers which in the first case were incoming will now be outgoing, and *vice versa*. The directional relays are also installed if the time of an incoming line is lower than an outgoing line further from the source. This must be checked separately for each end, in turn, considered opened at the generator station.

To secure the operation of the directional relays under bad power-factor conditions, connections are made so that the maximum torque is obtained with lagging power-factor. This may be accomplished by

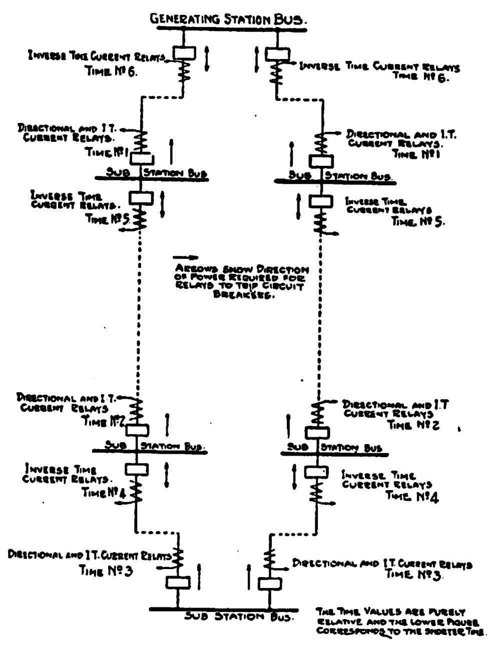

Fig. 2.—Inverser Time Current and Directional Relays as Applied to Ring System.

using directional relays with step-down transformers several schemes of connections of the potential and current elements, which schemes may not be interchangeable with different types of directional relays.

Some operators have found it advantageous when (particularly if not paralleled on the primary side) or reactors, to connect the voltage elements of the relays to the bus side of this apparatus in order to give a higher voltage in case of short circuit, thereby obtaining better operating conditions for the directional relays.

Balanced Protection Schemes for Transmission Lines.

Many operating companies have installed on a portion of their lines protective equipment designed to be inoperative so long as the currents in different circuits or at different points in the same circuit are substantially equal. To this end they have made use of (a) fully insulated lines in parallel between stations, (b) conductors in parallel having reduced separating insulation, *i. e.,* split conductor cable, and (c) pilot wires of relatively small cross-section between the two ends of a line to sense the degree of balance of the currents at these points. The basic principles involved are discussed below, which principles are sufficiently flexible to allow application in various ways to the problem which may be in hand.

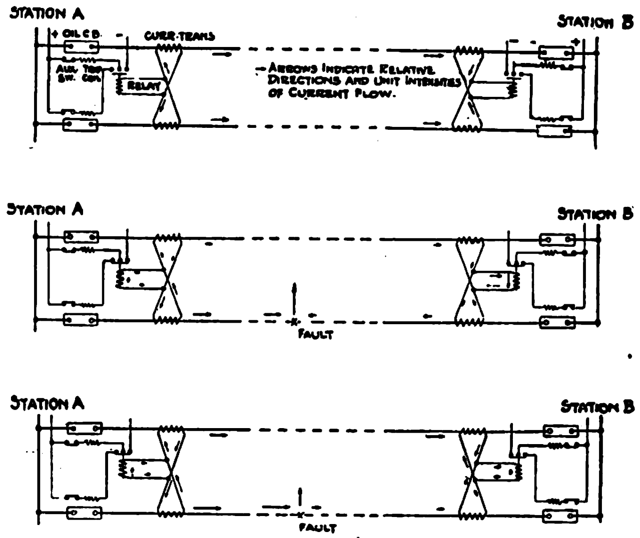
In the various diagrams accompanying the descriptions of these balances schemes, arrows are inserted to indicate the relative direction of current or of power. These arrows show power normally flowing from station A to station B. In each case, however, the equipment is equally suitable for power flowing in either direction.

In general, the over-current relays used are adjusted to operate instantaneously or nearly so. Some companies report that the opening of the breaker is so rapid that there have been cases where a cable has immediately rehealed, due to hot insulating material flowing into the opening made by the fault. Usually the point of breakdown has been actually located by subsequent inspection.

Balanced Protection of Two Parallel Lines (Not Discriminating).—The exceedingly simple scheme of balanced protection illustrated (Figs. 3, 4, 5) has given excellent results in a system so arranged that the lack of discrimination on the part of the relays between the sound and the injured line of a pair is not very vital. On the system referred to, each substation having such relay scheme, is provided with power over at least two different groups of lines. The complete, though temporary, interruption of one of these sources does not therefore kill the bus in question, and no hardship is imposed greater than the inconvenience of determining the good line preparatory to replacing it in service without its mate. This inconvenience is to a considerable extent compensated for by the freedom of the equipment from all alternating-current potential connections. While these potential connections, in present day relays, do not occasion the misgivings they were responsible for in older types, their elimination is a point not to be overlooked.

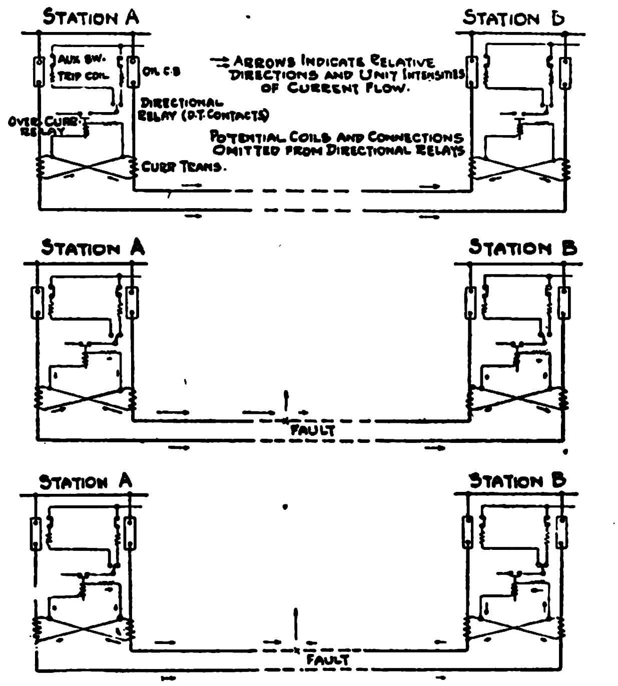
The balanced equipment, as shown above, consists of "cross connected" current transformers in the similar phases of the two lines, to the equi-potential points of the secondaries of which an over-current relay is connected. So long as the currents are equal and in the same direction in the two lines, there will be no current to flow through the relay coil, as demonstrated by the arrows on the secondary circuits. A through short circuit will not, therefore, improperly open these circuit-breakers providing the line characteristics are such that a suitable balance is maintained.

Assuming a fault, as shown in Fig. 4, there is an unbalance of currents at substation A and a relative reversal of current at substation B. The differential



Figs. 3, 4 and 5.—Balanced Protection for Two Parallel Lines (Not Discriminating).

of the secondary currents pass through the over-current relays, being an arithmetical difference at substation A and an arithmetical sum of substation B. Due to the differential current in the relay coils, the latter cause contacts to close, which trip both circuit-breakers at each end of the two lines. Following such operation it is reported to be the practice to find the healthy line and connect it in service with time over-



Figs. 6, 7 and 8.—Balanced Protection for Two Parallel Lines (Discriminating).

current protection (not illustrated in the diagrams) in place of the differential protection. If, at any time, the fault should occur so near station B that the currents at station A remain balanced, then the station A relay would not operate immediately, but at B the differential current would be very great, due to the reversal in the relative directions. Station B would, therefore, clear quickly, after which there would be established a large differential at A. An open circuit in either of the lines will likewise unbalance the pair and result in its isolation.

In order to protect against short circuits on the substation bus itself, or any possibility which would not give a relative unbalance or relative reversal of current on a parallel group of lines, the generator ends of all feeders are provided with inverse-time limit relays having comparatively high settings. It might be added here that with faults on the feeders between the generator station and substation, the substation relay clears the pair of lines from the substation, usually so quickly that the inverse-time limit relay on the faulty line, only at the generator end trips, thus leaving the good line of the pair connected at the generator substation.

Assume now a restricted fault in one of these lines, Fig. 5, such that the power direction remains throughout as formerly although the intensities have changed. It will be noted that the resulting difference in the currents in the two lines is reflected in the secondaries where it appears as a current through the relay coils and, causing the contacts to close, trips both circuit-breakers at each end of the two sides.

Balanced Protection for Two Parallel Lines. (Discriminating.)—In order to obtain discriminating action in the relay equipment for short circuits in either of two parallel lines, direction relays are included in the scheme previously shown in Fig. 3. With this modification the arrangement is as illustrated in Fig. 6. It should be noted that in case of an open circuit in one of these, selective isolation of the broken line is not obtained. The resulting unbalance would cause the opening of the sound feeder at one end and of the broken circuit at the opposite end, in case of sufficient current flow, as determined by setting of the time-current relay.

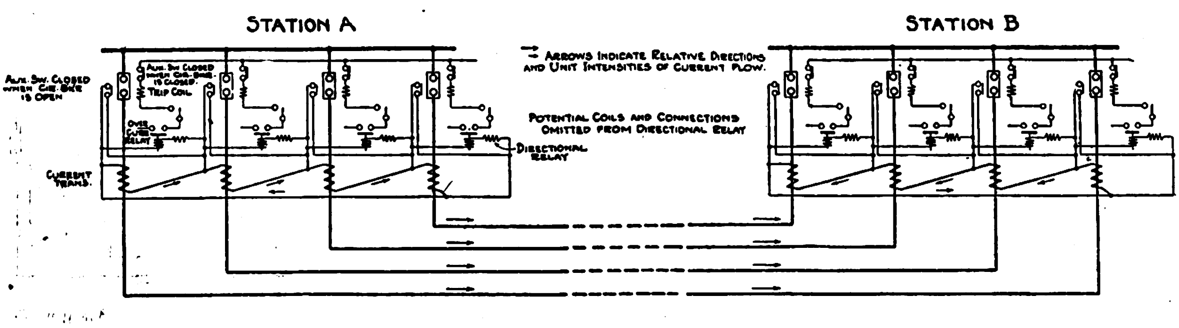
As in the previous case, so long as a balance is maintained between the corresponding phases in the two lines, no current flows in the differential or relay circuit. When a fault occurs, however, the vectorial unbalancing in the main circuits will be indicated in the relay coils, as illustrated in Figs. 7 and 8.

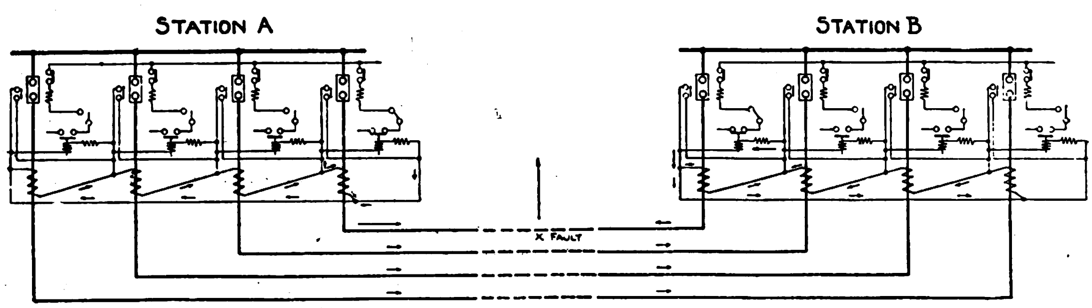
Looking at the matter from another viewpoint, if we assume for the moment that only one line is in service, then the current and potential connections to the directional relay should be so made that for power flowing from the bus to the line the contacts would close on the side to trip the breaker of the line in service. When both lines are working, the circuit having the greater flow of power from the bus to the line will control the operation of the directional relay and, therefore, trip the breaker of the line in trouble which always carries the greater power from the bus to the line.

It should be born in mind that power flowing from the line to the bus is of negative value, therefore, for cases such as shown in Fig. 7, where power flows from the line to station B bus over both circuits, the circuit having the greater flow from bus to line is the one having the least flow from line to bus.

In the event of one line being in service alone, it is the general practice automatically, by means of auxiliary switches on the circuit-breakers, to introduce time, over-current relays in the protective equipment which will operate in conjunction with the directional relays in a manner similar to that described in connection with Fig. 1 or Fig. 2 (tandem groups or loop circuits). This time delay also serves to prevent the opening of the sound line immediately following the tripping of the faulty one. In place of the single directional relay with double throw contact, it is also possible to obtain substantially the same results with two sets of relays with single-throw contacts arranged in a manner similar to that described for the protection of three or more parallel lines and shown in Fig. 9.

Balanced Protection for Three or More Parallel Lines (Discriminating).—Where a number of parallel lines are involved the underlying feature is the same as described in connection with Fig. 6, although the treatment of the matter is necessarily different. Here...





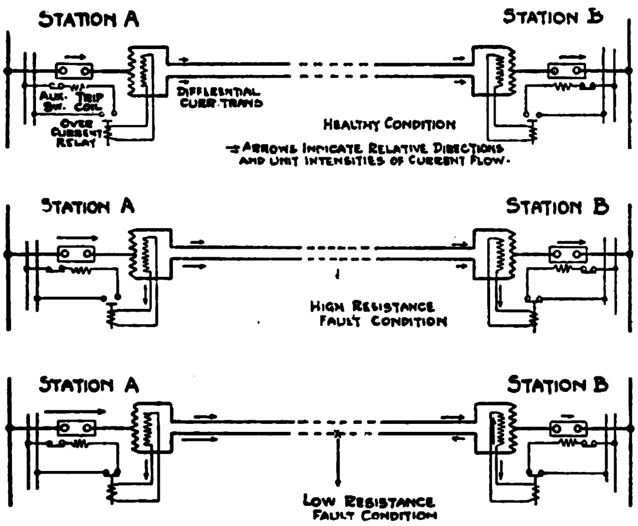
Figs. 9 and 10.—Balanced Protection for Three or More Parallel Lines (Discriminating), and Effect of Fault in One Line.

as shown in Fig. 9, the current transformer secondaries are connected all in series in a loop circuit so that, when the primary currents are all equal, the secondary currents will also be equal and will circulate through the loop as one current of the magnitude of each, and practically none will pass through the coils of the over-current and directional relays which are connected across each current transformer secondary.

Fig. 10 illustrates a fault in one line such that power is reversed at station B in this line from the direction taken by the remaining sound lines. It will be observed that only in the case of the injured line is the power direction through the directional relays (as indicated by the arrows) such that the contacts will close. At station A this is because there is a preponderance of positive power flowing from the bus into this particular line. At station B the injured line is the only one having positive outward flowing power.

Inasmuch as the success of the scheme depends upon the relatively low impedance of the loop circuit as compared to the impedance of the coils, it will be apparent that some method should be provided to eliminate the useless impedance injected in the loop circuits by the relays of a dead feeder. This is usually done automatically by short circuiting, by means of auxiliary switches on the circuit-breakers, or by auxiliary relays controlled by such auxiliary switches, the relay equipment of the line whose circuit-breaker is open.

It will be noted that when all but one line is out of service, the relay equipment of this last line will be



Figs. 11, 12 and 13.—Split-Conductor System Protection.

short circuited by the auxiliary switches or relays referred to in the preceding paragraph and accordingly the last line will be non-automatic unless some means is provided to open the loop circuit. This opening of the loop may be accomplished manually or it may be done automatically with considerable complication of auxiliary switches, etc., which complication is usually considered inadvisable. When the loop has been opened, each feeder will be left with over-current and directional protection at values determined by the settings of the over-current relays. Various other, also somewhat complicated, means may be used for inserting additional relays for the protection of this last line which on account of their variety will not be described here.

If an open circuit should occur in one of the conductors or if, when putting another line into service only the breaker at one end is closed, an unbalanced condition will result which may tend to open the good lines in use if the current flowing at the time is sufficiently great. This danger becomes relatively smaller as the number of lines involved is increased because the secondary unbalancing will be inversely proportional to the number of lines in service. For instance, if the over-current relays are set to operate at the normal load of each feeder and if four lines are in

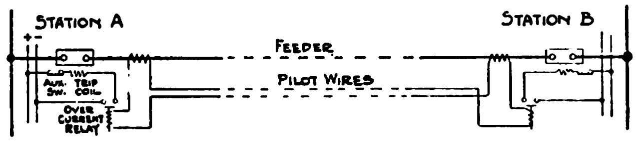


Fig. 14.—Pilot Wire System With Balanced Pressures—Merz-Price System.

(three continuous and one open at one point), an overload of three times normal on each feeder would be required before any trouble could be encountered.

Split Conductor Protection.—Split conductor cables are being tried out in this country by two operating companies who report good results to date. The cable is comprised of six conductors, each of the three phases being "split" into two halves.

The healthy and faulty conditions are illustrated in Figs. 11, 12 and 13. The action of relays is similar to that described in connection with the two-parallel-line equipment shown in Figs. 4 and 5, excepting that under end fault conditions, additional devices are required to provide the necessary unbalancing.

Pilot Wire System with Balanced Pressures.—Adaptations of the Merz-Price protective system have been used by two operating companies. One of these reports very satisfactory results, the other is not so favorable due to an inherent difficulty in obtaining the proper degree of balance.

Fig. 14 illustrates the scheme of connections. The current transformers in each end of the circuit have their secondaries connected in opposition so that when current flows through the feeder, a potential is produced across each current transformer secondary. As

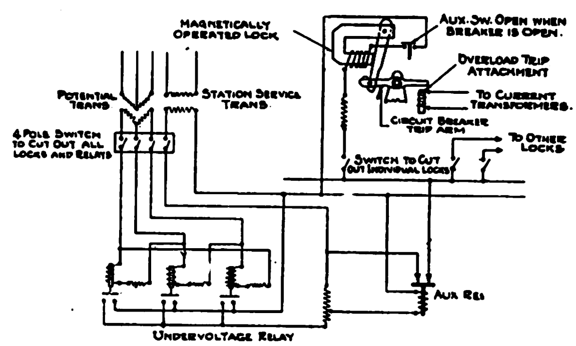

Fig. 15.—Undervoltage and Overcurrent Relay-Scheme of Connections.

these pressures, at the two ends of the line, are produced by equal currents passing through similar transformers, they also will be equal and, being in opposition, no current will flow.

If, however, the input to the cable exceeds its output the corresponding potentials across the transformers will become unbalanced and a current will pass through the pilot wires and, at the same time, through the relays connected in series at each end. The operation of these relays serves to trip the circuit-breakers.

Combination of Under-Voltage and Over-Current Relays for Protecting Transmission Lines.

One of the companies reported an application of a combination of under-voltage and over-current relays for their system which has given them very satisfactory results.

In this scheme all the circuit-breakers in any section are mechanically locked in the closed position by means of a magnetically operated lock. It is controlled by a voltage relay which releases the lock when the voltage falls below a predetermined value (approximately 70%). Upon the occurrence of a short circuit the voltage drops and when it has fallen below the predetermined point the voltage relays act to unlock the circuit-breakers which are then free to be opened by the over-current relay or other over-current device. Thus, in most cases only the breakers in the affected section can open on short circuit. It sometimes happens, however, that when two stations are close together, breakers in an unaffected section may be unlocked but usually the over-current device will act to open the proper ones only and clear the trouble before the others can operate.

Referring to the diagram, Fig. 15, the under-voltage relays are connected to the secondaries of potential transformers on the line buses. An auxiliary relay is actuated from the station service transformer and is controlled by the under-voltage relays. In its turn this auxiliary relay controls the locks on the circuit-breakers. One set of under-voltage relays, with the auxiliary relay, may control a number of locks on a number of circuit-breakers. The operation is as follows:

When the line potential drops below a predetermined value, one or more of the under-voltage relays drop and short circuit the auxiliary relay through a resistance which causes this auxiliary relay to open. This, in turn, releases the latch and leaves all the circuit-breakers under its control free to operate in case of over-current. Thus, so long as the potential remains above the predetermined value, no breaker can be opened by its automatic over-current feature.

This scheme, illustrated in Fig. 15, is reported as giving successful results on an overhead system covering 4000 square miles where there is a large number of stations located on an average of approximately 10 miles apart. As the lowest voltage occurs nearest the short circuit, it is probable that only the circuit-breakers in the immediate vicinity will be unlocked and allow the circuit-breakers to be automatically opened if the current is of sufficient magnitude.

Further information on this subject of relay protection will be found in papers by Philip Torchio entitled "Relays for High Tension Lines," and by R. F. Schuchardt entitled "Protective Relays," A. I. E. E. Proceedings, Vol. XXXVI, 1917, pages 361 and 383, respectively; and a paper by W. H. Cole on the subject of "Split Conductor Cables—Balanced Protection," Vol. XXXVII, page 793, A. I. E. E. Proceedings.

MANUFACTURE OF ELECTRICAL WIRING DEVICES IN OPORTO.

An industry of increasing importance in the consular district of Oporto, Portugal, is the manufacture of electrical wiring devices, according to the recent report of Consul Samuel Hamilton Wiley. This industry is in the hands of a Portuguese company, the Empreza Electro Ceramica, capitalized at about $375,000, fully subscribed, financed by local capital. The factory is located at Vila Nova de Gaya, a suburb across the Douro river from Oporto.

This company was organized about three years ago for the manufacture of the porcelain parts of electrical wiring devices, to supply the local demand for these articles which were formerly imported, chiefly from Germany. The venture has been a marked success, as the company is not only supplying the greater part of the local demand, but is exporting its products in increasing quantities to Spain, France, England and Brazil. Although the war is over this trade is expected to increase.

Output of Factory, Now Large, to Be Increased Shortly.

The plant covers an area of about three acres and consists of a modern installation for the manufacture of all porcelain wiring devices, for both high and low tension, and for the manufacture on a small scale of the metal parts of such devices. The manufacture of the metal parts has only recently been commenced. About 800 workmen are employed, and four large furnaces are operated in the manufacture of the porcelain parts. The preparation of the kaolin for use in the manufacture of the porcelain is carried out in the plant. All the steel molds, fire-clay receptacles, and other accessories employed are manufactured in the plant. With the exception of the metal used, all the raw materials are of local origin and are obtained from nearby. The production capacity of the factory is as follows: High-tension insulators (up to 15,000 volts), 1000 a day; low-tension insulators, 5000 a day; small insulators, fuses, switches, rosettes and other devices, 225,000 a day. With equipment now being installed the company hopes soon to double the present capacity.

Porcelain electrical wiring devices of the various types used in France, England, Spain and Brazil are produced, and many devices of German invention are initiated and improved upon.

American Co-operation Desired.

It is the intention of this company to greatly increase the output of its plant, and to endeavor to secure a large share of the trade in electrical wiring devices in European and South American markets formerly held by Germany. The greatest difficulty in the carrying out of this plan is the manufacture of the metal parts. Difficulty in obtaining raw materials and machinery for the manufacture of these parts prevents their being produced in quantities sufficient to complete the porcelain parts turned out. To insure the best results it is necessary to adjust the metal parts to the porcelain at the time of manufacture.

To overcome this difficulty this company desires to form a combination with some American company engaged in the manufacture of the metal parts of electrical wiring devices. Such metal parts to be manufactured in the United States and sent here for adjustment to the porcelain parts at this plant, or a factory to be established here in conjunction with the porcelain plant. The company here has excellent facilities for the manufacture of the porcelain parts of electrical wiring devices, and the plant is well situated geographically for the distribution of the products to European and South American markets, with quick deliveries.

Central-Station Rates in Theory and Practice

Outline of a Series of Articles on this Important Subject to Appear Weekly Throughout this Volume — H. E. Eisenmenger, Who Has Devoted Years of Research to Subject, Is Author

RATES for electric service are now to a large extent in a state of transition. Many central-station companies are being called upon to defend rates that were raised during the war and that are now being attacked because the war is virtually over. Other companies are being compelled to seek rate increases because there is no prospect of very material lowering of labor costs and costs of fuel and other supplies, so that the deficits involved in continuance of their present rates have threatened to wipe out previous surpluses or reserve funds and seriously impair net earnings.

Any rate revisions will very likely from now on be scrutinized with much more care than during the war when everyone recognized the emergency then existing and all new rates will be subject to severe scientific analysis and criticism. The whole subject of electric rates is therefore a very live one and should be given most careful study by central-station executives and all others interested in seeing fair rates established and maintained.

THE ELECTRICAL REVIEW has arranged for a very timely series of articles covering the entire subject of central-station rates in a very comprehensive manner and in such a way that will be found useful to every student of electric rates, *both the beginner and the expert*. These articles will cover about five or more pages of each weekly issue practically throughout the present volume, beginning next week, July 12, and probably ending Dec. 27, 1919. To suit the needs of various classes of readers, those portions dealing with elementary explanations for the beginners and those portions treating the technical features mathematically will be inserted in slightly different type, so that either of these portions can be passed over by the reader who does not care to or cannot follow these minor portions of the general text. The entire series of articles forms a connected whole, however, and besides being a comprehensive and original review of the entire subject includes much new matter which the author has developed.

A fairly good general idea of the scope of the entire series of articles can be obtained from the following:

GENERAL OUTLINE OF THE ARTICLES.

PART I—THE COST OF ELECTRIC SERVICE.

I. The Cost of Commodities in General.

A. THE COST OF A CERTAIN QUANTITY. TOTAL COST AND UNIT COST.

B. COST INCLUDING OR EXCLUDING CAPITAL EXPENSES.

C. SEGREGATE COST, INCREMENT COST AND AVERAGE COST.

D. BY-PRODUCTS.

E. PRODUCTS TO BE MEASURED IN MORE THAN ONE UNIT.

1. GENERAL EXPLANATION.
2. USING A SMALLER NUMBER OF ELEMENTS SIMPLIFIES THE COMPUTATION, BUT REDUCES THE ACCURACY.
3. USING A LARGER NUMBER OF ELEMENTS INCREASES THE ACCURACY, BUT COMPLICATES THE COMPUTATION.
4. INCREASING THE ACCURACY WITH A GIVEN NUMBER OF ELEMENTS BY SUBDIVIDING THE CUSTOMERS INTO CLASSES.

II. The Cost of Electric Service in Particular.

A. THE THREE ELEMENTS OF COST.

1. THE ENERGY COST.
2. THE DEMAND COST.
   - A. THE TOTAL DEMAND COST OF THE PLANT.
     1. *Capital Invested.*
     2. *The Constituents of the Demand Cost.*
        - a. Capital Charges.
          1. Net Returns (Interest, Dividend).
          2. Depreciation.
          3. Repayment.
          4. Other Capital Charges.
        - b. Demand Cost of the Plant Other than Capital Charges.
   - B. APPORTIONMENT OF THE DEMAND COST BETWEEN THE CUSTOMERS.
     1. *The Peak Responsibility.*
     2. *The Theoretically Exact Basis.*
        - a. Apportionment to Individual Customers, Considering the Shapes of Load Curves (Diversity-Factor).
     3. *Central Station's Peak Extending over a Certain Period of Time.*
     4. *The Consumer's Maximum Demand and Substitutes Therefor.*
     5. *The Diversity-Factor.*
     6. *Variations of the Demand Cost per Kilowatt Maximum Demand Between Customers.*
3. THE CONSUMER COST.
   - A. CAPITAL CHARGES.
   - B. OPERATING EXPENSES.
   - C. INFLUENCE OF THE CONSUMER COST ON THE TOTAL COST PER KILOWATT-HOUR.
   - D. VARIATIONS OF THE CONSUMER COST BETWEEN CONSUMERS.

B. DETERMINATION OF THE NUMERICAL VALUES OF THE THREE ELEMENTS OF COST.

PART II—THE PRICE OF ELECTRIC SERVICE.

PART III—SYSTEMS OF CHARGING.

PART IV—RATE ANALYSIS.

PART V—ACCURACY OF RATES.

PART VI—PUBLIC UTILITIES AND PUBLIC REGULATION.

(By S. F. Walker)

The Author—H. E. Eisenmenger.

The author of the articles is H. E. Eisenmenger, who has devoted a great many years of research to the subject of central-station rates. For about 10 years he has acted as assistant to S. E. Doane, chief engineer of the National Lamp Works of General Electric Co., in his rate investigations and similar central-station questions, such as serving the small consumer, codes of wiring, etc. As an outcome of these investigations there was formed the Rate Research Committee of the National Electric Light Association. A few years before the war Mr. Eisenmenger was sent to Europe for a year by the National Lamp Works, during part of which time he was accompanied by Mr. Doane; he visited all of the European countries to study conditions as to electric service and especially what means were taken to reach small customers. The results of this study created a great deal of interest.

Mr. Eisenmenger has worked with several committees of the National Electric Light Association, especially those on Rate Research, Wiring of Existing Buildings, and Wiring Codes. He is the author of numerous articles and papers on rates and related subjects and the originator of two different methods of geometrical representation of rates, one of which was explained in a series of articles in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN several years ago. For practically a year he made a tour among the central stations of the Pacific Coast in an educational campaign on rate subjects. Prior to his work in this country he spent considerable time in Central Africa erecting a 3000-volt central station for the British Government, and a year in Japan on export business. He is therefore well versed on electrical conditions generally in many countries of four continents and a specialist on electric rates to which he has devoted so much study both here and abroad.

CIVIL SERVICE EXAMINATIONS FOR RADIO POSITIONS.

The U. S. Civil Service Commission announces examinations for the following vacancies in the Navy Department, Washington, D. C., and in the navy yard service: expert radio aid, radio inspector and subinspector, radio laboratorian and radio laboratorian aid. Competitors will not be required to report for examination at any place but applications properly executed must be filed prior to the hour of closing, July 8, 1919. Applicants should apply at once for Form 2118. Applicants will be rated on the following subjects which will have the relative weights indicated: Education, training, experience and fitness, 80; publications, reports or thesis, to be filed with application, 20. Ability to send and receive wireless in the Continental Morse Code is very desirable.

Applicants for expert radio aid, Grade 1, $7.04 per diem, must have graduated from a standard high school or completed a course of study equivalent to that required for such graduation, and must have had at least four years' experience in the design or manufacture of radio apparatus for the Government or for a contractor who has supplied satisfactory apparatus of this class to the Government. The successful completion of each year in a college or university of recognized standing, with major courses in electricity, will be accepted in lieu of six months of the required experience. For Grade 2, $10 per diem, applicants must have the high-school or equivalent education and seven years' of experience prescribed for Grade 1 of each year in a college or university of recognized standing, being accepted in lieu of nine months of such experience. Applicants for Grade 3, $12 per diem, must have graduated with a B. S. degree from a four years' course in a college or university of recognized standing, with major courses of study in electricity, and have had (a) six years' experience in actual responsible administration of the design and manufacture of radio apparatus for the Government or by a company which has supplied satisfactory radio apparatus of this class to the Government; or (b) for six years have conducted advanced research work and made valuable contributions to the science of radio, and be well known to the technical world as an investigator of ability; or (c) a combination of the experience prescribed under (a) and (b) totaling six years.

Applicants for radio inspector, Grade 1, $6 per diem, must have graduated from a standard high school or completed a course of study equivalent to that required for such graduation. In addition, they must have had at least one year's experience in installing radio apparatus in shore or ship stations or in repairing and maintaining such stations in service. The successful completion of each year in a college or university of recognized standing, with major courses in electricity, will be accepted in lieu of three months of the required experience. For Grade 2, $7.60 per diem, applicants must have the high-school or equivalent education and three years of the experience prescribed for Grade 1, each year in a college or university being acceptable as six months of such experience.

Applicants for radio subinspector grade 1, $2.80 per diem, must have successfully completed seven units (usual two years) of high school, and must possess a first-grade amateur license as radio telegrapher. For grade 2, $4.40 per diem, applicants must have the education specified for Grade 1, and, in addition, must possess a commercial radio telegrapher's license, or have possessed for at least two years a first-grade amateur license as radio telegrapher.

Applicants for radio laboratorian, Grade 1, $6.40 per diem, must have graduated from a standard high school or completed a course of study equivalent to that required for such graduation. In addition, they must have been actually engaged for at least two years in the design and manufacture of radio apparatus by the Government or for a contractor who has supplied satisfactory apparatus to the Government. The successful completion of each year in college or university of recognized standing, with major courses in electricity, will be accepted in lieu of three months of the required experience. For Grade 2, $8.80 per diem, applicants must have the high-school or equivalent education and four years of the experience prescribed for Grade 2; the successful completion of each year in a college or university of recognized standing, with major courses in electricity, being accepted in lieu of six months of the required experience.

Applicants for radio laboratorian aid, Grade 1, $3.20 per diem, must have graduated from a standard high school, or completed a course of study equivalent to that required for such graduation. In addition, they must possess a commercial radio telegrapher's license or have possessed for two years a first-grade amateur's radio license. For Grade 2, $4.80 per diem, applicants must have the high-school or equivalent education prescribed for Grade 1, and must have been actually engaged for at least one year in the design or manufacture of radio apparatus by the Government or by a contractor who has supplied satisfactory apparatus of this class to the Government. The successful completion of each year in college or university of recognized standing, with major courses in electricity, will be accepted in lieu of three months of the required experience.

Editorial Comment

A Million Homes Needed

REAL ESTATE men at the recent national convention in Atlantic City reported that there is now a deficiency of something like 1,000,000 homes in various sections of the country as compared with the housing facilities available before we entered the war. Building to supply this deficiency has begun, but it must be accelerated. Electrical men will be sadly remiss if they do not see that the houses and apartments being, and to be, built are properly wired and liberally equipped with sockets and receptacles for convenient use of lighting units and appliances.

Scientific Central-Station Rates

COMPARED with other electrical utilities, the rates of the leading central-station companies are probably the most scientifically and equitably developed. And yet there are many such companies, especially the smaller ones, who have much to learn in this line. The present time, when rates are so largely being revised, is especially appropriate to become acquainted with the latest information on this subject. We take pleasure, therefore, in calling the attention of our readers to the valuable series of articles on central-station rates outlined on other pages of this issue and which will be begun next week. Even experts cannot know too much on this often involved topic and will find much of interest in the articles that Mr. H. E. Eisenmenger has written for the benefit of all having to do with electric rates.

The Street Railways' Case

OVER 13% of the electric railway mileage of the country, principally street railways, is in the hands of receivers. This is a striking indication of the desperate situation confronting these railways. The percentage of bankrupt lines will continue to increase if relief is not soon afforded to the hard-pressed companies. The high labor and other operating charges of the last year or two show no prospect of diminishing; in fact, in some cities the men are seeking wage increases beyond those granted last year.

We have repeatedly urged in these columns that the utility regulating commissions be empowered to pass on wage controversies so that when wage increases are found necessary they can be granted and the income adjusted to provide for them through increased fares or other additional revenue or relief from certain other expenditures. Little has yet been done along this line, but the need for it is greater than ever. The War Labor Board, after raising the wages, recommended to the state utility commissions increase in fares to provide the needed income. The state commissions have been reluctant to act in many cases, however, because lacking authority to review wage scales. It is to be hoped that the Federal Commission now studying the matter will be able to offer a satisfactory and early solution.

Coal Costs Favor Electrically Operated Ice Plants

THE electrically operated ice plant has come in for much publicity and adoption during the last few years for many reasons that have been mentioned many times in these columns. One of the reasons why this type of ice-making and refrigerating plant should be expected to continue is that the cost of coal is high and has every indication of remaining high.

At a meeting of the American Society of Mechanical Engineers, held last December, it was stated that, on an average, there are far more plants requiring one ton of coal to every 1.5 to 2.5 tons of ice produced than there are plants producing 5 tons of ice per ton of coal, these statements applying to simple non-condensing plants. With coal at present prices, the cost of fuel per ton of ice has doubled and trebled in a brief period. Many steam-driven plants are now paying from $1.50 to $2.00 for fuel alone per ton of ice. And then there is the high cost of labor also to be taken into consideration.

Conditions are now extremely favorable to the electrically driven ice and refrigeration plant, and conditions show little indication of radically changing for considerable time to come. Now is the time to go after this load.

Making the Storage of Coal Safer

STORE your coal now, the slogan of a year ago, is still a good slogan today. It should be the slogan every year at this time, because this is the season when the storing of coal should be done, when the output of the mines needs to be maintained, when the railroads can best haul coal.

This year there are many special incentives to buy coal now. The Fuel Administration states a coal shortage will ensue this winter. The Secretary of Labor says a labor shortage impends. The Director General of Railroads predicts a car shortage. These things are all against the production and movement of coal; they are cumulative in inflating prices. Therefore buy your coal now.

However, the summer months are, unfortunately, the least favorable months for storing coal, at least so far as the possibility of spontaneous combustion is concerned. But by following certain clearly defined policies trouble from internal heating of the coal pile can be greatly lessened and possibly eliminated. The safety of coal in storage depends partly upon the coal, but more perhaps upon the manner in which it is stored.

Avoid if possible storing coal that has the reputation of firing when stored. Store, preferably, 4-in. or 6-in. screenings, the portion passing through the screen to be used for current consumption. Keep the coal from one mine and seam together; from different mines separate. In choosing a pile site, avoid rough, hilly, soft, wet and boggy ground. Clear the ground of all vegetation, waste and dirt, and drain if it will not otherwise remain dry. Combustible material such as wood, rags and old clothes become hazards when buried under a coal pile. All sources of heat such as steam pipes, sewers, etc., have no place in proximity to a coal pile.

Coal fires spontaneously by the oxidation of fine coal particles presenting a maximum surface for the air to act upon. Coal, well screened and carefully piled seldom fires, because there is a minimum surface subject to oxidation. Store only approximately uniform coal sizes together because it is where the coarse and fine strata come together that a fire generally starts. Where this cannot be done adopt any of the several ways of watching the internal temperatures of the pile. When these things are done, spontaneous combustion in coal piles will lose most of its dread.

Is Not Co-operation the Solution to Today's Problems?

CO-OPERATION was the theme of Prof. C. A. Adams' presidential address before the A. I. E. E. convention at Lake Placid. In masterly style and with oratorical ability he touched upon many of the problems that are perplexing the world today. Into the problems of standardization, of labor, of capital and industry he brought the message of co-operation, harmony and understanding.

Every engineer should read and read again this presidential address. It is a challenge to some; it is a benediction to others and an inspiration to more. Engineers have been far too prone to consider themselves in the light of engineers, forgetting that they are citizens also. And no more valuable citizen should there be than the engineer with his training and his ability to utilize that training for his city, for his state and for his country.

Unquestionably the engineer can do much in developing solutions for many new vexatious economic, social and political problems. His approach of a problem without prejudices and his calm analysis of the conditions before attempting to pick out the remedy makes his final solution the most logical as well as most practical.

"May we not as engineers utilize our training and experience, our method of thought of which we are so proud, to encourage clean, straight, unbiased and fair-minded thinking, and to encourage that broad, generous co-operative spirit which will mean so much in breaking down the barriers which separate classes within a nation, as well as the nations themselves, and which is essential to the solution of the world problem which is knocking so hard at our door?"

The above, quoted from President Adams' presidential address, asks squarely and tersely what engineers are going to do in solving the pressing world problems of today. What, indeed, are we doing to give the engineer the place in the world that he deserves, that the world needs that he assume now?

Transmission-Line Relay Protection

RELAY protection has assumed very great importance of recent years. And the indications are that it will become even more important as time goes on. Today, many high-voltage transmission systems might more properly be called distributing systems. Systems are linked together, industrial substations and utility switching stations and substations are tied-in together in ring and radial systems so as to form a complete and complicated network in which each is an integral part of the whole.

Present-day standards require continuity of service to a very high degree. The growing complexity of networks, the vaster terraine covered, the greater magnitude of energy transmitted and interchanged between ever-growing loads makes relay protection against short-circuits and reversal of power and the segregation of power cessation vitally important and at the same time very difficult to obtain.

That this matter of relay protection is a pressing one is emphasized by the fact that a considerable portion of the program of the A. I. E. E. convention at Lake Placid was devoted to relay protection and allied subjects. For many years some of the largest transmission companies have been quietly and painstakingly tackling this problem of confining trouble where it occurs, segregating sections of line and substations in trouble and in other allied ways aiming to attain the goal of service continuity. Relay and protection engineering has thus become a recognized phase of central-station technique among those larger companies that tie in steel mills, electric furnaces, industrial plants and many more such loads with their ring and radial systems of high-voltage distributing systems.

Elsewhere appears an abstract of the very able report by Messrs. Roper, Woodrow, Traver and MacGahan on "Transmission-Line Relay Protection." This is an analysis of the protective relay situation throughout the country, and should thus be found enlightening to those that have already studied the matter seriously, and prove an inspiration to those whose systems are only now beginning to feel the need for something better than a hit-or-miss mode of protection.

Relay protection against short-circuits is not only a matter of protecting apparatus. More important still, perhaps, is its function of maintaining continuity of service. Cheap power is important. But central-station service is judged today, not by cost but by quality. Continuity of service is, therefore, vital. Relay protection has done much and will yet do more to make continuity of service and central station synonymous terms.

Popularizing the Convenience Service Outlet

ELSEWHERE in this issue, a definite, practical plan to promote the installation of baseboard and wall outlets, which has been introduced by Mr. John G. Learned, chairman of Commercial Section, N. E. L. A., is described. For many years the electrical industry as a whole has recognized the need for the more adequate installation of such outlets but until now no real workable plan has been evolved therefor.

The value of such outlets is now apparent to every electrical man for they affect every branch of the industry—manufacturer, contractor and dealer, central station, jobber and the electrical inspector. Of these, the latter is the only one that has hitherto given the problem any consideration and it is only fair to say that he deserves the thanks of the industry for not having adopted some arbitrary means of combating this difficulty before.

However, Mr. Learned's plan in itself is a worthy one and deserving of the fullest support and cooperation of all parties concerned. The plan as laid out provides for an educational campaign to create a demand for these outlets from the public. The first part of this campaign is to be carried out by the manufacturers of electrical appliances who in their advertising and displays will show their devices connected to a wall, floor or baseboard receptacle. This will impress the public with the convenience of such outlets and naturally create a demand for them. The rest is up to the contractors, dealers and central stations. If these interests will get behind the idea and through their efforts and example try to "put it across," one of the greatest barriers to the use of electric power and appliances in the home will be removed and the results will surely prove worth while.

Spread of Estimators' Organization

BEGINNING with the organization of the Chicago Electrical Estimators' Association about a year and a half ago, the idea of forming associations composed of electrical estimators has grown steadily until at present there are at least five such organizations composed only of estimators and several more that, although they include others in their membership, are making a study of estimating problems. These associations have already accomplished a great deal toward standardizing electrical construction and in addition have brought forth considerable data which should stabilize the contracting business. For the estimator is the heart of the contractor's business and upon his work and ability often depends the contractor's success or failure.

However, there is still a considerable amount of work to be done along these lines, which can best be undertaken by such associations, much of which is dependent upon local conditions and can therefore be accomplished more readily by local organizations. For this reason not only the contractors but the jobbers, central stations and manufacturers should encourage and foster such organizations where they exist and endeavor to have others formed wherever possible.

The Forty-four Hour Week

ORGANIZED labor throughout the world is tending toward better working conditions and shorter working houhs. Last week the American Federation of Labor went on record unanimously as advocating a 44-hour week. It went further, by forecasting a five-day week to take care of unemployment. British unions have already adopted a 44-hour week in some cases; although let it be said the workers are now finding it a two-edged sword.

The shorter day for the same pay is not the same in result as higher wages; the latter stimulates efficiency and increases production. Shorter hours for the same pay almost invariably means higher production costs and lower production. This will tend toward higher prices unless the employer can obtain more output per employe per hour to offset the shorter working hours. In some cases this cannot be done without forcing the men to work more intensively. In many cases it can easily be done, however, without driving anyone harder. This has been shown by the greater and greater use of machinery in almost all industries. Machinery and the use of more scientific and efficient production methods is permitting more output to be obtained during the present customary 48-hour week than during the former 60 or 64-hour week. We have by no means reached the climax in the use of automatic and labor-saving machinery.

It is impossible to foretell just what will be the effect of a shorter working day. It certainly will necessitate the adoption of more efficient methods in industry and more intensive employment of machinery, electrically driven. In industries, such as the steel mills and foundries, it may mean higher load-factors, because of the necessity of maintaining double shifts in many cases. In fact, the need for increased efficiency and production will in many industries compel working three shifts throughout the 24 hours per day.

Workmen in former days used to combat the use of machinery. Nowadays they recognize that through machinery their hours of work have steadily grown less and their condition as steadily has improved.

Current Events

Engineering Society Celebrates Fiftieth Anniversary—Central-Station Men Convene—Ruling on Competitive Service

WESTERN SOCIETY OF ENGINEERS CELEBRATES FIFTIETH ANNIVERSARY.

Review of the Society's Growth and of the Engineering Developments of Fifty Years.

On June 27 the Western Society of Engineers celebrated its fiftieth anniversary. Two meetings were held on that day in the rooms of the society at Chicago, the first one being in the afternoon, at which the Past-President H. J. Burt presided in the absence of President Baldwin, who was called out of the city. Secretary E. S. Nethercut read a paper reviewing the history of the organization, which was formed May 25, 1869, as the Civil Engineers' Club of the Northwest. It was the third engineering society formed in the United States, the two preceding ones being the Boston Society of Civil Engineers, organized in 1847, and the American Society of Civil Engineers, organized in 1852. At the present time there are 15 national engineering societies, beside a great many state and local organizations.

Only two of the original charter members of the Engineers' Club of the Northwest survive. The first president was Roswell B. Mason, then mayor of the city. In June, 1880, the club was reorganized and its name changed to the Western Society of Engineers. In 1908 the present quarters in the Monadnock Block were enlarged and have become the chief engineering headquarters in the Chicago district. Up to 1909 the membership of the society was practically doubled each 10 years, but since then its growth has been much slower because the national societies at that time began the establishment of local sections. The Chicago sections of these societies hold meetings jointly with the Western Society of Engineers very frequently and in its rooms.

Many notable papers have been presented before the society, among these being several dealing with the investigations in aerial flight by Octave Chanute, a former president of the society. The society's code of ethics has a number of unique features. A standard of length was set up in the City Hall of Chicago through the influence of the society. The latter also took a prominent part in the passage of a law licensing structural engineers. Mr. Nethercut in conclusion pointed out the possibilities for the society becoming in a still larger sense the headquarters for engineering organization activities in the district tributary to Chicago, in which there are some 5000 members of various engineering societies, a large part of whom should have membership connection with the organization.

Samuel O. Dunn, editor of the *Railway Age,* reviewed the developments of 50 years in railroad engineering. The railroad engineers of this country have had an entirely different task from those abroad, because they had to build lines to develop the country, instead of merely furnishing transportation in sections already developed. In 1869 the first transcontinental line was opened and from then on up to 1895 there occurred an enormous building of railroad lines, especially in the West. Since that time the development has been more in the way of intensifying traffic and facilities along lines already built. As an instance of the growth in train weights, Mr. Dunn cited that when the Interstate Commerce Commission was established freight trains averaged about 175 tons, whereas now they average about 700 tons. A similar increase in length and weight of passenger trains has occurred. Railroad development now is at a crisis because of high labor and material costs, which call for more efficient utilization of each. The question of returning the lines to private ownership is a very difficult one. Although Mr. Dunn has some misgivings regarding the future of railroad development, he feels that the public will not let the lines suffer and thereby impair the commercial and industrial progress of the country.

James R. Bibbins gave a review of the developments in steam and power engineering, which he said were especially noteworthy since the beginning of this century. From very small sizes steam turbines have grown to extraordinary capacities. Boiler units also developed from 250 hp. to duplex units of 3000 hp. rating, with enormous and very efficient combustion chambers and a stoker at each end. Extreme care has been given to study and design of the parts of steam turbines, to the utilization of higher pressures and superheats and to the use of higher speeds. The outcome has been the gradual development of the very large units of today. At the same time important developments have taken place in the way of generators and other rotating electrical machinery and other power plant auxiliaries. Much of this has been made possible through the developments in the metallurgical line, which have permitted the imposing of much more severe strains upon metals and alloys. Together with the growth in capacity has been an extraordinary advance in efficiency in every step of the process of power production from the coal pile to the busbars. In the case of the largest turbo units the thermodynamic efficiency at the best load now is nearly 25%, which has given the internal-combustion engine a very close race. Improvement in reliability has also taken place, as for instance improved condenser practice has practically eliminated air troubles and the water that leaves the condenser is practically the same temperature as the entering steam. Organization of power plants has also been highly developed. Remote control is now largely used because of its simplicity and directness at the command of the load dispatcher. Many automatic protective devices, indicating and recording instruments are now employed, so that the operation has been highly perfected. As the result of the increase in size of units the installation cost has been decreased from something from $150 per kw. to about $70. At the same time the over-all commercial efficiency has been very greatly raised.

J. R. Cravath gave a review of the developments in electric lighting and power applications, all of which took place within 50 years. During the 70's the electric motor was developed and a few years later the arc lamp, followed in the early 80's by the introduction of incandescent lamps, and in the later 80's by the use of motors for electric railways. The alternating-current developments began in the early 90's and soon resulted in the growth of power distribution systems or networks, which have become very extensive especially since the beginning of the present century. Machine drive is now almost entirely electrical, whether power is derived from the central station or an isolated plant. Electric lighting developments have been very rapid and now electricity has replaced almost everything else in the illuminating line, even on the farm. Especially in lamp and lighting development the result of research has been of untold value.

Frank F. Fowle gave a review of developments in electrical communication, especially in telephony. He reviewed the development of the telephone from the inventions of Dr. Bell and the gradual growth that took place during the life of the original basic patents. After these expired great stimulus was given to the industry, many independent manufacturing and operating companies entering the field soon after 1895; now there are about 13,000,000 telephone stations in the United States. During the late 80's took place the development of simultaneous telephony and telegraphy on the same wires; later the introduction of Pupin loading coils extended long-distance telephone service. The use of repeating coils aided this further and during the last few years the use of the vacuum type of repeater, based on the audion, has given telephony wonderful possibilities. The automatic telephone was first developed by the independent telephone interests. The war has aggravated the operating troubles of all telephone companies, due to higher wages and scarcity of operators, so that the automatic telephone is undoubtedly going to be put into quite extensive service, as soon as the companies can provide the necessary heavy financial investment required. A change is now coming about through gradual abandoning of the open overhead wire lines and converting them to cable lines, either overhead or underground; the use of the audion repeater has made this commercially possible and this will make for great increased reliability of service during storms. The audion has also made possible the use of multiplex telephony.

John W. Alvord gave a review of sanitary engineering, showing that from 90 to 95% of what we call modern sanitation has been developed within 50 years. Since in the early 80's, when the study of bacterial origin of disease began, water and food supplies have been very materially purified. The filtering of water supplies is now carried out very extensively. Water works systems have become common only since about 1880. The treatment of sewage and other wastes, as well as the purification of water supplies has helped increase the average human life from 23 years at the close of the 18th century until about 40 years in 1900. Typhoid fever is no longer a serious menace. Whereas 20 years ago it was common to have 20 to 120 deaths per 100,000 persons annually from this cause, now this seldom exceeds 5 deaths for the same number.

After dinner at the Chicago Engineers' Club, an evening session was held in the rooms of the society at which Col. Henry A. Allen of the 108th Engineer Regiment was the principal speaker. He gave a general summary of the history of this regiment, which was originally the First Regiment of Engineers, Illinois National Guard. Soon after the outbreak of the war it was increased in strength, trained at Camp Logan and sent to France. Colonel Allen gave an interesting account of the various experiences of the regiment in building all kinds of structures for the expeditionary forces, as well as bridges and other military works close to and frequently in advance of the firing line. He spoke very emphatically in favor of thorough preparedness and much longer training than was possible during the recent war. A soldier should have at least two years of training and an officer from 4 to 6 years. To rush insufficiently trained troops into service under insufficiently trained officers is practically committing murder, because of the absolutely unnecessary sacrifice of the men involved thereby. He also emphasized the need of thorough equipment.

The remainder of the evening was devoted to addresses by past presidents of the society. The society has had 41 presidents, of whom 17 have died. Of the remaining, 12 were present at the meeting. Addresses were made by Past-Presidents S. G. Artingstall, Isham Randolph, John F. Wallace, Ralph Modjeski, William L. Abbott, C. F. Loweth, Andrews Allen, John W. Alvord, Albert Reichmann, H. J. Burt and Charles B. Burdick. Most of these addresses were of a reminiscent character and several of the late past-presidents pointed out the opportunity for the society as the engineering headquarters for Chicago. Communications were also read from Past-Presidents W. B. Jackson, W. C. Armstrong, B. E. Grant, R. W. Hunt and E. H. Lee, and from a former secretary, J. W. Weston, and Mr. Blunt, one of the charter members.

Saturday, June 28, was devoted to an all-day outing at the Dunes, a very interesting geological sand formation with a great variety of botanical specimens at the southern end of Lake Michigan in Indiana.

INDEPENDENT TELEPHONE MEN DISCUSS THEIR PROBLEMS IN CONVENTION.

Annual Gathering of United States Independent Telephone Association Held in Chicago June 24-26.

A very well attended annual convention of the United States Independent Telephone Association was held at the Hotel La Salle, Chicago, on June 24 to 26. inclusive. The 900 odd delegates and guests were welcomed to Chicago by E. T. Stevens, of the Chicago Association of Commerce, and O. F. Berry replied for the association. In his annual address President G. W. Robinson, St. Paul, reviewed the principal features of the association's work and its importance to the industry. He referred to the taking over of the telephone lines by the Government last year and said that, on the whole, the companies had benefited thereby.

Secretary-Treasurer W. S. Vivian, who recently returned from service in France, in presenting his annual report made many valuable suggestions on how the association could develop and increase its service to its member companies. He urged employment of practical specialists in several branches of telephone work. A committee was appointed to consider means for putting Mr. Vivian's ideas into effect. L. E. Hurtz, of Lincoln, Neb., narrated his experiences in Washington, D. C., assisting F. B. MacKinnon in representing the independent companies before congressional committees and various executive branches of the Government, especially since the Government took over the lines.

At the Wednesday session the election of ten members of the board of directors was effected, after which

Capt. Terry W. Allen, of Jackson, Tenn., spoke of the strenuous work of the Signal Corps in France. B. J. Mullaney, Chicago, described the publicity campaign of the Illinois Committee on Public Information. Samuel Insull, president Commonwealth Edison Co., spoke on "The Present Position of Public Utilities," as reported in our last issue.

A luncheon session was then held at which H. F. Atwood spoke on "Our Constitution—an Antidote to Bolshevism." F. B. MacKinnon, vice-president of the association and for many years its representative at Washington, D. C., spoke at length on the work accomplished at the capital. He reviewed in detail the steps taken when and since the Government took over the lines and interpreted many orders of the Postmaster-General and also his general policy.

During the afternoon the board of directors held a meeting at which F. B. MacKinnon was elected president of the association for the ensuing year; Frank L. Beam, J. B. Earle and W. F. Goodrich were elected first, second and third vice-presidents, respectively. President-elect MacKinnon presided at the concluding session on Thursday. O. A. Knell, St. Paul, Minn., presented a paper on "Choosing Employes by Test." Dr. F. A. Wolff, of the Bureau of Standards, led a discussion on telephonic standardization, in which A. B. Smith, H. D. Currier, and R. H. Manson participated. Miss M. Martin spoke of the work of the girls with the Signal Corps in France. After addresses were made by several other incoming officers and resolutions were adopted approving the rate changes made by the Postmaster-General, the convention adjourned.

IOWA SECTION, N. E. L. A., HOLDS INTERESTING MEETING.

Features of Public Utility Management Brought Out at Annual Convention at Colfax.

Public utility management was the principal topic of discussion at the annual convention of the Iowa Section, N. E. L. A., held on June 18, 19 and 20, in Colfax, Iowa. According to the preliminary announcements sent out, this convention offered an opportunity to get a four-year course in this subject in three days and from the variety of excellent papers presented, together with the lively discussion that followed, it is evident that this contention was true.

In his opening address, President Bellamy made several valuable suggestions intended to further the activities of the section and broaden its scope and pointed out the difficulties being encountered by many companies due to the higher costs of labor and materials. These advances, he explained, would not be overcome by operating economies and it was therefore necessary to increase the rates in many cities.

William Chamberlain, general counsel of the United Light & Railways Co., Cedar Rapids, Iowa, then addressed the members on "Rate Litigation in Iowa," in which he described the difficulties encountered by many utilities in securing necessary rate increases. Following Mr. Chamberlain, Dean William G. Raymond, of the State University of Iowa, explained the work of the Board of Conciliation which rendered valuable assistance to the utilities during the war but, being purely a war-time measure, will be dissolved shortly. Other papers presented during the meeting which dealt with the subject of rates were: "Rates as Affected by the Increased Cost of Production and the Attitude of Regulatory Bodies Thereto," by X. A. Warfield, Illinois Traction System, Peoria, Ill., and "Principals to Be Observed in Determining a Rate for Electric Service in Cities Under 5000," by Prof. J. B. Hill, of Iowa State University. At the conclusion of Professor Hill's address a lively discussion ensued which brought out very clearly the value of having a uniform method of determining rates for service in the various localities in the state. W. A. Jones, of the Empire District Electric Co., Joplin, Mo., explained the accounting system recommended by the Accounting Section of the N. E. L. A. for use in small plants. Prof. F. O. Paine, of Iowa State College, told of the four-day course in meter testing for the employes of small plants which was conducted during the past winter and described the many valuable results which had been obtained.

The principal addresses at the banquet were delivered by John F. Gilchrist and E. W. Lloyd, both of the Commonwealth Edison Co., Chicago. Mr. Gilchrist's address dealt with public relationship and the advantages of securing the good will of the public. Mr. Lloyd described the work which is to be carried on by the national association during the coming year and its effect on the local section activities.

Several interesting and instructive papers relative to farm services were also presented, the principal one being "The Electric Transmission Line and Telephone Interference Situation in Iowa With Respect to Farm Line Service," by H. S. Phelps, electrical engineer, Iowa Railroad Commission. From the discussion it is evident that the companies realize the necessity of devising some means of serving the farmer for the demand for such service has grown tremendously in the past few years. Several other addresses were also made which dealt principally with municipal ownership and socialism.

The meeting closed with the election of officers for the coming year which resulted as follows: President, O. H. Simonds, Dubuque; vice-president, J. P. Ingle, Keokuk; secretary-treasurer, M. G. Lind, Des Moines. The following directors were also chosen: Austin Burt, Waterloo; B. G. Schmidt, Elkrader; Paul Myers, Grinnell; John Drabelle, Cedar Rapids; C. E. Burke, Sioux City; F. J. Hanlon, Mason City; Charles Miller, Claremont; C. G. Johnson, Davenport; C. E. Farney, Ottumwa, and F. W. Brooks, Omaha.

NEBRASKA CENTRAL-STATION MEN HOLD ANNUAL CONVENTION.

Probable Effect of Coming State Constitutional Convention on Utilities Principal Topic of Discussion.

The Nebraska Section of the National Electric Light Association held its annual convention at Grand Island, Neb., June 18 and 19. The meeting this year proved to be exceptionally interesting, for in addition to the usual technical discussions, several interesting addresses on public relationship were presented.

J. E. Davidson, of the Nebraska Power Co., Omaha, president of the section, presided during the meeting and also delivered a very interesting address in which he reviewed the effects of the war-time conditions on Nebraska central stations and explained that the efforts to meet these conditions which will undoubtedly prevail for some time to come, should be continued. He also pointed out the need of co-operation among the members in order to secure the proper support of the state authorities which would enable the companies to overcome these conditions.

Charles Kelsey, of Norfolk, Neb., described the probable effect of the coming constitutional convention on public utility companies. This convention has been called to remodel the present state constitution and will undoubtedly incorporate in the new constitution some measures affecting the utility companies. The exact nature of these measures cannot be determined as yet, but the utilities should exert every effort to secure proper legislation. At present, the only work that can be done is to educate the public to the utilities' problems and thus secure their co-operation.

Another interesting paper entitled "The Man in the Street" was read by R. J. Andrus, Grand Island, Neb. In this paper, which was written by S. M. Kennedy, of the Southern California Edison Co., Los Angeles, Cal., the necessity of securing the co-operation of the general public and the methods to be followed in accomplishing it were clearly brought out. J. M. Smith, of Omaha, presented a paper on the "Sale of Utility Securities to the Public" in which he pointed out the value to the utility of taking the consumer into partnership by making him a shareholder. In addition the "Attitude of the Public Toward Utility Companies" was described by F. E. Helvey, of Lincoln, Neb.

The work which is being done on the National Electrical Safety Code was described by Mr. Sahm of the Bureau of Standards, Washington, D. C. In addition the following papers were also presented: "New Business," by W. S. Byrne, of Omaha, Neb.; "Modern Steam Central-Station Practice," by H. A. Lynette, Chicago, and "Safety Measures and Accident Prevention," by C. B. Scott, of Chicago.

The following officers were elected: T. H. Fritts, Central Power Co., Grand Island, Neb., president; James B. Harvey, Nebraska Power Co., Omaha, vice-president. J. E. Shuff of the Lincoln Gas & Electric Co., Lincoln, Neb., is at present secretary, but arrangements are being made to provide for a paid appointee to this position.

At the close of the meeting an inspection trip was made to the new hydroelectric station of the Central Power Co., at Boelus, Neb.

PENNSYLVANIA SUPREME COURT MAKES IMPORTANT RULING ON COMPETITIVE UTILITY SERVICE.

The State Supreme Court, Pennsylvania, has handed down a decision in connection with the application of the Perry County Telephone & Telegraph Co., Landisburg, Pa., to the Public Service Commission for permission to construct a new line between New Bloomfield and Newport. The Court upholds the Commission in its refusal to permit the company to construct the line; the Commission held that the present service to these communities, as rendered by the Perry County company and the Cumberland Valley Telephone Co., was fully adequate. In this the Commission maintained that the construction of the line under the circumstances would double the capital charge upon which the public would pay and would also divide the service between two companies so that the same public would be required to rent two telephones in place of one in order to reach all local users.

In sustaining this view, the Supreme Court establishes important precedents as regards so-called ruinous competition by public utilities and says, in part:

"Competition may be and is very desirable in many lines of business; there are, however, a number of quasi-public enterprises which may be classified as natural monopolies in case the duplication of facilities merely results in the placing of an additional burden upon the public by forcing persons to maintain two systems where one would serve the purpose as effectually and at less cost. In this class may be placed the furnishing of gas, water, electricity and telephone service to the public. The argument that competition between rival facilities serves to reduce the price to the consumer is not sustainable logically.

"The duplication of telephone systems, for instance, in a given locality without connection between their lines requires subscribers to install both systems and pay double service to reach subscribers on but one of the two systems. Or, as frequently happens, subscribers maintain both systems when they can reach other users with equal facility on either system.

"It is useless to argue that the cost of construction of such duplicate systems is paid by investors and the risk of financial failure is theirs, because to the burden of finally paying the carrying charges, and income to the investors is imposed upon the public with the result that a higher charge on the part of each competing company becomes necessary, due to the division of the patronage of the public. This is especially true in the smaller cities and country districts where the public to be served is limited in numbers. To hold, therefore, that public policy, as indicated by the section of the constitution in question, was intended to permit the construction of competing lines under any and all conditions without inquiry into the character of the territory to be served and the existence in the locality of facilities adequate to accommodate the public, would amount to a destruction of the very object the policy is designed to establish."

ELECTRIFICATION OF RAILWAY IN BRAZIL.

A director of the Central of Brazil Railway, Government owned and operated, has presented to the Minister of Communications plans for the electrification of the suburban lines of the road and the trunk line from Barra to Pirahy, as well as general plans for the suburban service and the closing of the roadbed from the main station to Deodoro.

The Commission chose high-tension, direct current for the suburban service, and recommended that the current be purchased from one of the existing power companies rather than have the company install a plant of its own.

The approximate cost of the rolling stock, substations, aerial lines, etc., is estimated at $4,307,377. This does not include the cost of car sheds at the main station and at Deodoro.

The first work to be undertaken will be fencing in and raising the level of the track in order to avoid accidents. It is believed that by closing in the lines the revenues of the suburban service will be greatly increased, as such a step will facilitate a better fiscalization of the passenger receipts. This work will probably cost about $1,398,238, the estimate being based on the prevailing prices of materials.

The director added that in case the total amount required for this work was not available during the present fiscal year, it would at least be well to begin the work of closing the line, as a half million dollars was appropriated for this purpose in the budget law for this year.

Upon receipt of the plans, the Minister of Communications approved them and directed that the work of closing in the line from the central station to Deodoro be initiated.

Commercial Practice

Vigorous House-Wiring Campaign — Live Window Displays—Truck Fleet Large Power User—Message by Movie

DUQUESNE LIGHT CO. PUSHING VIGOROUS HOUSE-WIRING CAMPAIGN.

Aims to Wire Five Thousand Houses by the End of the Year.

The Duquesne Light Co. is pushing a vigorous house-wiring campaign, that is a very ambitious one. Special effort is being made to wire old houses, and the high mark or goal the company is after is 5000 such houses in the Allegheny and Beaver Counties of Pennsylvania. A new reduced electric light rate goes into effect on July 1, and this, coupled with the campaign and healthy conditions, leads the company to look for the most prosperous year in its history so far as concerns the wiring of houses and obtaining the residential load.

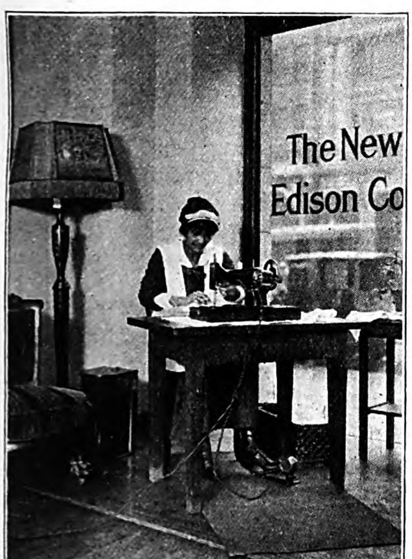
The greatest year in the company's wiring history was in 1917, when 2612 houses were wired. During the first five months of that year 940 old houses for wiring were secured. During the first five months of this year the company actually closed 1804 contracts for wiring old houses in Allegheny County alone, as compared with 1829 for the whole of 1918. In Beaver County, 270 contracts have been closed, as compared with 200 during the whole of 1918. This means that for the first five months of this year a total of 2074 old house-wiring contracts have been obtained, whereas the total for the entire year of 1918 reached 2029. It is in face of these facts that the company faces with enthusiasm and faith the campaign which carries with it the slogan, "5000 Wiring Contracts by Jan. 1, 1920."

LIVE SHOW-WINDOW DISPLAYS BRING MANY SALES.

New York Edison Co. Finds Window Demonstrations of Labor-Saving Devices to Have Great Drawing Power.

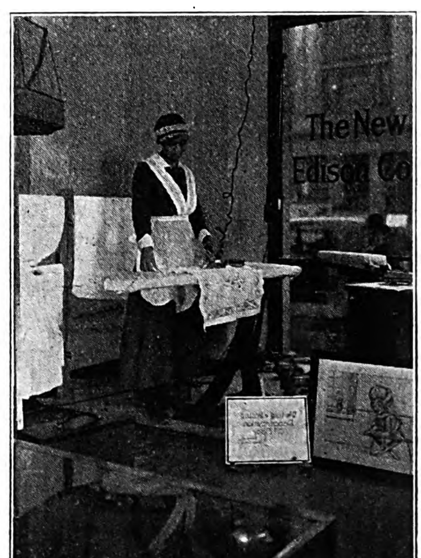
An elaborate system of window demonstrations of electric labor-saving devices for the home has been instituted by the Showroom Committee of the New York Edison Co., New York City, and is producing most satisfactory results in increasing the sales of household appliances. This window-display work was begun last December simply to catch the attention of the Christmas shopping crowds that pass along Forty-second street, that busy up-town thoroughfare where the Edison company has a branch office. The demonstrations, however, were so successful that they have been extended to seven of the company's showrooms and recently, by special arrangement, to the showroom of the Yonkers Electric Light Co., Yonkers, N. Y.

For each week a different subject is selected. Thus, the first week might be washing and ironing; the second, cooking on small electric appliances; the third, sewing by motor-driven machine; and the fourth, vacuum cleaning. The windows are arranged to represent home conditions as much as possible and to give reality; real work is done, not merely the lifeless doing the same thing over again, which is the bane of most window demonstrating. Blankets and small rugs are washed in the laundry machines, features which have scored among the women in the crowds gathered to watch. When cooking is done in the window, the women outside are invited to step in and



Electric Sewing Machine, Operated by a Uniformed Attendant, Proves Excellent Show-Window Attraction in New York Edison Co.'s 42nd Street Showroom.

Electric Dish-Washing Exhibit Ready to Go Into Display Window—Where Customers Cannot Afford to Purchase a Dish-Washing Machine, Electric Fans Are Recommended for Drying.



The Electric Ironing Window Demonstration Produces More Orders Than Any Other—After a Week in the Window This Exhibit Was Used in the Showrooms and Still Brought Sales.

sample the food, to convince them that it does taste as good as it looks. When vacuum cleaners are demonstrated, not only rugs are cleaned, but clothes, curtains, cushions and sofa pillows, to suggest the wide usefulness of a cleaner in an actual home.

Although these extensive demonstrations were intended originally for the crowds along Forty-second street only, when the showroom orders began assuming a marked ascent, other of the larger offices requested demonstrations. Then experimentally, a vacuum cleaner exhibit was made for a few days in the window of one of the smaller offices, in a location supposedly not favorable to this method. Within a few days, ten cleaners were sold there; needless to say, it was arranged to continue demonstrations in this supposedly "unproductive" territory. With the smaller offices, however, the best results are obtained by having demonstrations on alternate weeks, so as not to exhaust local interest. As an added attraction for the summer, window demonstrations of drying and preserving fruits and vegetables will be made, using electric fans for drying and an electric fireless cooker for canning.

A rather surprising item of this campaign has been the extraordinary success of an ironing exhibit arranged at first simply as a background for a window demonstration of washing and ironing. Behind the window was arranged a large table filled with flatirons of every type and make, and nearby stood a demonstrator, who ironed all day long without apparent effort or fatigue. During the first week of this exhibit, orders were taken for a daily average of 14 irons, and the showroom force requested its continuance until the sales fell away. That was two months ago, and the pulling-power of the exhibit has remained almost undiminished. At a conservative estimate, nearly $2500 worth of orders have been taken at a cost of between 5 and 6% of the amount represented.

These demonstrations also follow out the well-known policy of the New York Edison Co., as determined by Arthur Williams, general commercial manager, to have Edison showrooms take orders for manufacturers, but not to have the company go into the selling business on its own account. Customers attracted by the demonstrations go into the showrooms where they see appliances representing the products of the best known manufacturers, who in this way, profit as well by the advertising value of the "live" windows. On the other hand, the Edison company believes that it gains more than the actual new business as the demonstrations tend to increase the usage of apparatus already on the lines, when people in passing the windows see some of the less common applications of the devices illustrated by the demonstrators. Although not so spectacular as the widely advertised and elaborately conducted flatiron or cleaner "week" usually advocated, the net results of this new form of sales-pushing indicate that it is more satisfactory for a city of the size of New York.

ELECTRIC TRUCK FLEET GOOD CONSUMER OF ENERGY.

Fleet of Thirty Trucks Uses Nearly 11,000 Kw-hr. Each Month.

The Duquesne Light Co. operates a fleet of 30 electric trucks in Pittsburgh in connection with its business. These trucks are giving a good account of themselves as to work, while proving economical as to operation.

The average energy consumption of these 30 electric trucks averages about 10,900 kw-hr. each month, or about 364 kw-hr. per truck per month. On the basis that the average family uses about 18 kw-hr. per month the year round, the energy consumed by this fleet of 30 trucks is about the same as would be consumed by 7266 houses during one month, or 605 houses for a whole year. This fact emphasizes the value of the electric truck as a load builder, it being borne in mind that the energy consumed by these vehicles is consumed at a time when the houses or residents would be using little if any.

THE ELECTRICAL MESSAGE TO MILLIONS VIA THE MOVIE ROUTE.

Society for Electrical Development Displays Seven Educational Films to Exporters.

On June 27 there was held a review of seven motion-picture electrical films prepared by the Society of Electrical Development and one by the Western Electric Co. This exhibit was unique in its inception and its execution.

Not long ago, Mrs. May Savell Croy, an expert on electrical house furnishings, installed a complete electrical kitchen and laundry in the beautiful new Bush Terminal Sales building at 130 West Forty-second street, New York. This is part of an "ideal cottage" in which the wonders of electricity are explained to visiting importers, exporters and buyers from all over the world.

Exporters who recently visited the Bush Sales building were interested in knowing that a film had been made the previous day at Mrs. Croy's exhibit and wanted to know where they could see it. The film, "Table Cookery," was developed by the Society for Electrical Development and the Universal Film Co. So, for the special benefit of the exporters and by courtesy of the Bush Terminal Co., an exhibit was arranged at which the Society's films and one of the Western Electric Co. were shown, and to which also were invited prominent men of the industry in New York, Brooklyn, New Jersey, and the members of the Society in the Metropolitan District. Also there were in attendance newspaper men, representatives of the trade press, and the women household editors of prominent magazines.

The Society's staff works with various film companies to offer electrical suggestions, correct errors and devise useful educational propaganda. The Society has prepared over a dozen special electrical moving-picture films, in conjunction with the Universal Film Co., and has worked with the Western Electric Co. and other manufacturers and jobbers to the same end.

DEVICE CAMPAIGNS FLOURISH IN ARKANSAS.

The commercial department of the Arkansas Valley Railway, Light & Power Co., Pueblo, Colo., is conducting a series of campaigns on electric household devices. A recent electric washing machine campaign resulted in the sale of 18 machines and prospects for many more. An electric vacuum cleaner campaign is now in progress and later another campaign will be opened on the small labor saving electric appliances. In a recent week local contractors secured in co-operation with the company's commercial department, orders for wiring 52 already-built houses.

Operating Practice

Reducing Flash-Overs of Converters — Generator Waterproofing — Relay Engineering — Identification of Piping

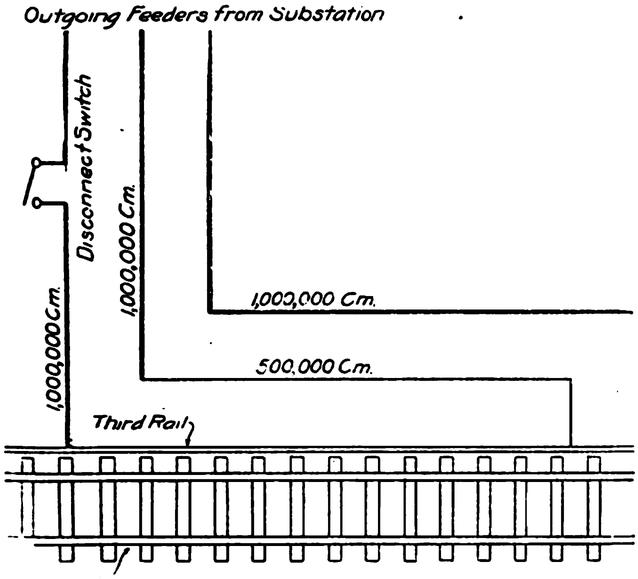
REDUCING CONVERTER SHUT-DOWNS BY CHANGING FEEDER LENGTHS.

Variable Feeder Lengths According to Loads Overcomes Trouble.

It has been the experience of companies supplying electric railroads with direct current that trouble is to be expected when the synchronous converters are located at heavy load centers where the loads are heavy and the feeders of short length. Such locations are those where a substation is located directly at a railroad terminus or freight yard. In these instances the third rail or trolley may be used as a feeder, and feeder lengths may be short. The result is that a heavy swing of current due to trouble on the railroad reacts directly back to the station bus.

One manner in which this trouble may be overcome is to increase the length of the feeders or insert resistance so as to increase the equivalent feeder length —that is, the resistance of the circuit. And then the introduction of resistance is not the same as the introduction of inductance, resistance being effective while current is passing through it, while inductance is effective only while the current value is changing. Obviously, therefore, the introduction of inductance is preferable to the insertion of resistance since it affects the circuit—the voltage regulation—only when actually needed, namely, on current change.

In one instance where a substation was located



Schematic Layout of Railway Feeders for Changing Equivalent Feeder Length With Load.

directly at a large electric terminal yard, the current rushes due to short circuits were very severe. When two synchronous converters were operating these short circuits only opened the feeder breaker, but when one machine was operating alone its breaker would open, shutting down the converter, and sometimes causing it to flash over. There were a number of heavy feeders going to the yard. Two of these were of 1,000,000 c.m. and about 300 ft. in length. One of these tapped directly to the third rail; the other connected to a 500,000-c.m. cable which tapped to the third rail some 1000 ft. away.

Flash-overs and the opening of the machine circuit-breakers occurred only when one synchronous converter was operating. The trouble was overcome in the following simple and inexpensive manner. In the substation basement, the 1,000,000-c.m. cable that connected directly to the third rail was cut open and connected to a disconnect switch of sufficient current-carrying capacity. During comparatively light load periods, when only one synchronous converter was used, this switch was opened by the operator and left open, the effect of which was to feed the third rail over the feeders having 1000 ft. of additional length. The result was that the low resistance of the 300 ft. of 1,000,000-c.m. conductor was eliminated, thereby reducing the current rush on short circuit, and yet without increasing seriously the voltage drop at the normal current of light load. When the load increases sufficiently to warrant operating two converters, the disconnect switch in the short 1,000,000-c.m. feeder is closed.

WATERPROOFING TURBOGENERATOR WINDINGS.

Generous Use of Varnish Lessens Objections to Use of Water.

Considerable publicity has been given of late to the matter of fireproofing turbogenerators and how best to fight internal fires when they do occur. Water, steam, carbon tetrachloride and carbon dioxide have been suggested, with water and steam in preference on the score of cost, availability and safety.

In using steam cognizance must be taken of its effect upon insulation and to what extent the heat and moisture will cause disintegration of cambric and varnishes. The insulation of turbogenerator windings may be divided into three classes, all-fibrous, composite and all-mica, and each of these will be affected differently by both water and steam.

All-fibrous insulation is now used only on the older machines, and is not waterproof in any sense of the word. Composite insulation is made up of mica tape, is treated in a vacuum and finished with layers of tape which is fibrous material. By careful and generous application of varnish this composite insulation can be made to approach if not attain a waterproof condition. All-mica insulation is waterproof, except where tape is applied on the job, and here also several good coats of varnish makes this type of insulation waterproof.

Little fear need, therefore, be apprehended in applying water to turbogenerators whose windings are insulated with all-mica or composite insulation. On the other hand it should be made a special point when overhauling and doing the periodic annual repairs to the older types of machines using fibrous insulation to pay special attention to applying generous coatings of varnish so as to seal up this form of insulation lest the time come when it may be necessary to fight an internal fire with water or steam.

CONSIDERATIONS AFFECTING OPERATION OF OVERLOAD RELAYS.

By A. E. Hester.

No set rules can be laid down to govern the application of relays. Each and every power system has its own peculiarities and the choosing and setting of relays must be governed by these. However, if a careful study is made of the system and the conditions existing on each section are thoroughly analyzed no great difficulty should be encountered in securing satisfactory protection on any power distribution system. The accuracy and permanence of calibration of the modern induction type relay insure satisfactory operation if proper application is made.

In laying out a protective scheme on any system a great many factors have to be taken into consideration. The characteristics of the line and each piece of apparatus, generating, switching, transforming and converting, should first be carefully studied as this is what determines the amount of short circuit current available. In determining this short circuit current it should always be considered as due to a solid metallic short circuit with minimum generating capacity.

One method of determining the possible short-circuit current is to observe the voltage drop between two stations at normal load, when the short circuit current is given by $\dfrac{\text{Normal voltage}}{\text{Voltage drop} \times \text{load}}$

This is only approximate however and is very likely to give high results.

Another method is to determine the total impendance, including that of the generator between any point where the short circuit value is desired and the generator, then short circuit current $= \dfrac{\text{Star voltage}}{\text{Impedance}}$.

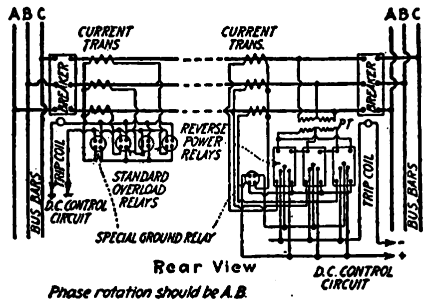
This gives the instantaneous short circuit, however, and the sustained value is much less, usually about 2 or 25 times full load current.

Unless a special scheme is used for disconnecting a line on a high resistance ground, as would be necessary in the case of a generator having its neutral ground through a comparatively high resistance, modern relays will not clear a high-resistance short circuit. This is no disadvantage, however, as a high resistance short circuit will invariably develop into an arc before any damage is done and since an arc has a very low resistance the effect of a metallic short circuit will be obtained and the relays will operate.

The various connections and combinations used on a system also deserve careful attention when laying out a protective scheme. First the number and location of the power sources should be taken into consideration. The main thing to be considered is whether or not there is more than one source, since a layout which would be suitable for a system having one source of power might not be suitable for another having more than one source.

It sometimes happens that a system has its neutral grounded through a comparatively high resistance and when a ground occurs conditions may be such that the trouble current is actually less than the full load current. Such a ground cannot be cleared by reverse power and overload relays connected to protect the system against short circuits.

This difficulty may be overcome by using an overload relay, constructed to operate on low currents,



connected in the neutral lead of the current transformers as shown in the accompanying diagram. Then under normal conditions no current flows through the neutral lead of the current transformer bank. But as soon as the ground occurs the unbalanced current flows through this lead and the ground relay and the circuit breaker is opened.

When used with overload relays the ground relay contacts so that its operation opens the circuit breaker directly. When used with reverse power relays, however, the ground relay contacts are used to short circuit the contacts of the overload element of the reverse power relays thus leaving the watt elements to discriminate as to the direction of power flow. This is clearly shown in the diagram.

It is possible by carefully studying and analyzing the conditions to secure automatic sectionalizing on any network regardless of its complications.

IDENTIFICATION SCHEMES FOR STEAM AND WATER PIPES.

In most power plants and electrical generating stations electrical circuits and control apparatus is marked and identified in a conspicuous and practical manner, because it may be necessary at any time to be able to identify and segregate a circuit, a circuit breaker, transformer, etc., at any time on short notice.

What is done for the electrical equipment should also be done with the apparatus for the steam and water. Both are as important as the electrical equipment; although it is true less attention and less hasty action is usually called for. High-tension wiring is often colored red, the low-tension blue or black. So too low and high-pressure steam piping should have colors that discriminate between them. Live and exhaust steam pipes, pipes for oil, for water for turbines and for house service should have distinctive colorings. Pipe coverings should be stenciled also.

In addition to distinctive coloring of pipes, it is well to tag them. Tags should be placed at locations where it would otherwise be difficult to trace continuity, for example where a pipe enters another chamber and turns around. All valves should be tagged. Using distinctive colorings for the different pipes saves time and lessens accidents due to mistakes. Stencils and tags serve to identify the various pipes of the same class of service.

Contracting-Construction

Connection and Operation of Autotransformers — Estimators' Association—Report of New York State Meeting

METHOD OF CONNECTING AND OPERATION OF AUTOTRANSFORMERS.

Use of This Device for Connecting Lights to Power Circuits Not Generally Understood.

By J. D. Bernard.

It is often desirable in large manufacturing plants using alternating current to connect the power and lighting circuits to the same source of supply. In this way the additional expense of a separate service for each of these purposes is avoided and, in plants where the power is purchased on a maximum demand basis, the demand factor is reduced because the peak periods do not occur at the same time. Although the voltage on such circuits is subject to fluctuations due to the starting of motors, etc., which also affect the lighting, it is suitable for use in many places where the work is such that steady light is not necessary.

In the majority of plants such circuits are three-phase, 220 or 440 volts. In order to use this service for lighting either high-voltage lamps must be used, the lamps must be wired in series or a transformer installed to reduce the line voltage. On account of the greater cost of the high-voltage lamps and the difficulty of using the lamps in series, the latter method is usually employed. The transformers may be either of the ordinary type having primary and secondary windings or it may be an autotransformer having but one winding with a middle tap brought out. On 220-volt circuits the autotransformer is generally used and from the difficulties encountered, it is evident that many contractors do not thoroughly understand the connection and operation of this apparatus.

The function of the autotransformer when used in this way is simply to supply a neutral wire having the same difference of potential from either of the line wires. Its installation on one phase of a 3-phase 220-volt system, therefore, is equivalent to a 3-wire, 110/220-volt system, as shown in the accompanying diagram. This neutral tap is only required to take care of the unbalanced portion of the load as the balanced portion can be considered as being in series across the line. For example, in the diagram eight lamps are shown connected to the circuit, three to one side and five on the other. If all these lamps were in use at one time, three lamps on one side would be in series with three on the other, leaving only the two lamps on one side that would be supplied through the autotransformer. If each of these lamps was of 200 watts capacity, the load on the autotransformer would be 400 watts while the entire load would be 1600 watts. It is evident therefore that the size of the autotransformer is dependent upon the size of the probable unbalance in the load. This unbalanced portion of the load will average about 25% of the full load but will vary according to local conditions and the wiring layout. The size of conductor to be used, however, is determined by the connected load and the same rule that is ordinarily followed in making 3-wire, 110/220-volt installations should be used.

When an autotransformer is used on a 3-phase system on which the neutral point of one of the transformers is grounded, as is the system shown in the diagram, it should be installed in this phase, rather than either of the other phases. The reason for this is that there is a difference of potential between the neutral point of either of these other phases and the ground which would prove dangerous should a ground develop in the wiring. Where for some reason it is not possible to install the autotransformer on this phase or where the system is not grounded, a ratio transformer having two windings is recommended. Such a transformer, of course, provides for the entire load and its size therefore must be determined accordingly.

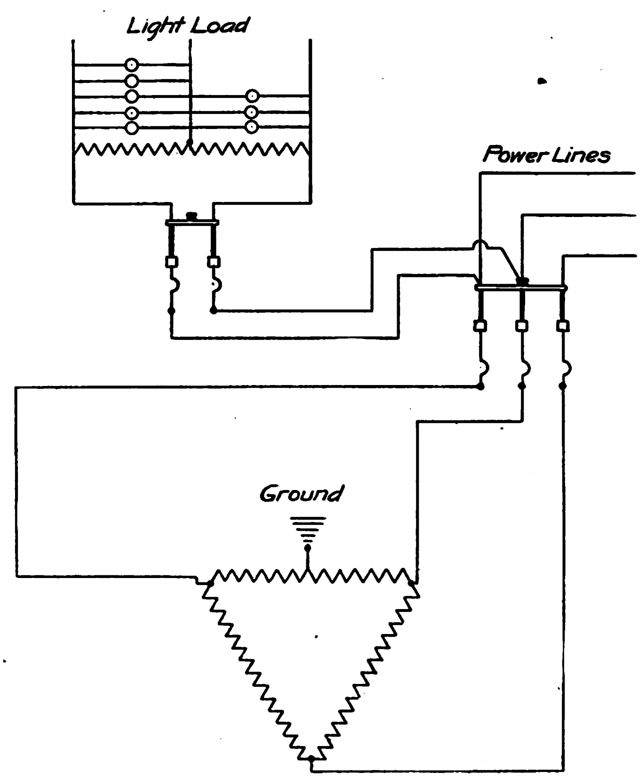


Diagram Showing Method of Connecting Autotransformer in 3-phase Power System.

In installing an autotransformer the switch or fuse protection should be connected ahead of the device rather than between it and the load. The reason for this is that should one of the fuses blow between the autotransformer and the load, the entire load on one side of the line would be carried by the autotransformer which would undoubtedly burn it out. With the switch connected ahead of it, however, the blowing of a fuse only cuts the service off. The actual connection of the autotransformer is very simple as the leads are always marked and only have to be connected to the proper lines.

NEW YORK CITY ELECTRICAL ESTIMATORS FORM ASSOCIATION.

Electrical Estimators' Club Organized to Study Conditions and Benefit Members.

The electrical estimators of New York City have organized an association to be known as the Electrical Estimators' Club of New York. According to the constitution the purpose of the organization is to study the values of the electrical devices and methods which may be included in making up an estimate of the costs of electrical construction: to promote more intimate acquaintance and good fellowship among those who estimate electrical work; also, by the interchange of experiences, ideas and assistance to raise the efficiency of its members. Membership in the club is open to any person estimating electrical construction work.

In order that the work of the club may be carried on as rapidly and efficiently as possible, several committees have been appointed, each to investigate and report on a certain subject. In order to stimulate interest in the association's activities among its members, the constitution provides that the appointments to such committees be so divided that as many individuals as possible serve on them. Other articles having the same tendencies have also been incorporated in the constitution. One of these is that every member, including the officers, should rise at least once during a meeting and express at least one thought on the subject under discussion. The other states that the officers shall be elected for a term of one year and, with the exception of the secretary, no officer shall be eligible to re-election to succeed himself.

John B. Curtis, of J. Livingston & Co., Inc., 70 East 45th street, has been elected president.

NEW YORK STATE CONTRACTORS DISCUSS BUSINESS RELATIONS.

Many Interesting Papers on this Subject Presented at Convention in Saratoga Springs.

All phases of the electrical contractor-dealers business were brought up and thoroughly discussed at the annual convention of the New York State Association of Electrical Contractors and Dealers held in Saratoga Springs, N. Y., June 23 to 25, inclusive. The success of the convention as well as the future success of the state association is indicated by the expressions from all groups of the industry who were present and took an active part in the proceedings. Chairman M. H. Johnson presided.

On Monday morning, prior to the formal opening of the convention a meeting of the Executive Committee was held at which the reports of officers and committees were presented and discussed. The treasurer's report showed the finance of the association in a very sound condition with a sufficient surplus for active organization work. The Insurance Committee recommended an agreement with Mr. Block of the Utilities Indemnity & Exchange for group insurance covering the membership policies through which a considerable saving in premiums will be effected. The Labor Committee, appointed at the January 1919 meeting was continued with instructions to prepare a universal form of agreement between labor unions and district associations, the members of which employ union labor. It is hoped through this course to standardize labor conditions throughout the state and avoid discussion and controversy which have been a source of more or less misunderstanding in the past and also obviate the possibility of any agreement clauses the legality of which might be questioned. The report of the Membership Committee showed that at the time of the transfer of the association from the old to the new constitution which occurred at the 1918 convention the membership was about 150 and is at present approximately 450, several new districts have been formed and the names of their Executive Committeemen submitted and approved.

The convention was opened with an address by Mayor Schwartz of Saratoga Springs in which he welcomed the delegates and their guests. W. C. Peet, chairman of the National Association, responded and, in the absence of W. H. Morton, described the work that was being done by the national body particularly in regard to the Data and Sales book and the new educational campaign. C. C. Dailey of Rochester, N. Y., then explained overhead costs and their application in estimating wiring. This feature of the contractor-dealers business although a very important one has been sadly neglected in the past but during the past year has received considerable attention. Mr. Dailey was followed by Lynton T. Block of the Utilities Indemnities & Fire Exchange, St. Louis, Mo., who described the operation and effects of compensation laws and liability insurance.

W. L. Goodwin of the General Electric Co., author of the Goodwin plan addressed the members on merchandising on Tuesday and on general topics of interest on Wednesday. Both subjects were treated in a way that he has never excelled if equalled, on previous occasions.

The other speakers on Tuesday were: Samuel A Chase of the Westinghouse Electric & Manufacturing Co., who described in a very interesting manner the "Channels of Distribution Between Manufacturer and Consumer," and which is reproduced, substantially in full, in another part of this issue. W. A. Kennedy of New York City, whose subject was "Wholesale Only and Its Co-operative Benefits;" J. T. Hutching, Rochester Railway & Light Co., who explained the effect of central-station rates for service on the contractor-dealers business. F. G. R. Gordon of Haverhill, Mass., spoke on "The Menace of State Socialism in America," which might be considered a departure from the usual routine of conventions; the information and statistics presented by him are a subject for serious thought for both business men and associations regarding fundamental obligations to their country as well as their business.

On Wednesday morning J. J. Raftery of New York City discussed the relations between the electrical jobbers and contractors. He was followed by Louis Kalischer, of Brooklyn, who delivered an interesting and instructive address on the "Advantages of Co-operative Selling Campaigns."

In addition to the regular sessions a meeting of the Joint Conference Committee, consisting of the representatives of the Empire State Gas and Electric Association, the Underwriters Association, and the New York State Association of Electrical Contractors and Dealers was held on Wednesday morning at which the previous work was gone over and their future program arranged. It was decided that its first activity will be the standardizing of services and meters in all districts of the state.

Contractor-Dealer

Plans to Encourage Installation of Convenience Outlets—Channels of Distribution from Manufacturer to Consumer

INSTALLATION OF CONVENIENCE OUTLETS TO BE POPULARIZED.

John G. Learned, Chairman Commercial Section, N. E. L. A., Introduces Plan to Promote Use—Of Interest to Contractor-Dealer.

Perhaps the greatest attempt that has been made thus far to promote the installation of outlets for the use of appliances is being introduced by the Commercial Section, National Electric Light Association through its chairman, John G. Learned of the Public Service Co. of Northern Illinois. In effect, the plan is an educational campaign to popularize the use of such outlets and thus to create a demand for them from the public.

Originally the manufacturers of electrical appliances, in their advertisements and window displays showed these devices connected to lighting fixtures. As their use in this manner was not approved by the inspection authorities and also because many of the more modern fixtures made such connections difficult, this practice was soon discontinued. Since this time the manufacturers have featured their devices showing the cord dead ended, that is, not connected to any outlet.

Through Mr. Learned's efforts several of the larger manufacturers have been asked to show their products in the future connected to a convenience service outlet. In this way the appliances can be illustrated in the most attractive manner and at the same time the added convenience of the outlet will be shown.

This campaign and the progress which has been made was outlined in a recent letter from Mr. Learned to E. W. Floyd of the Commonwealth Edison Co., which was read by O. R. Hogue at the recent convention of the Illinois State Association of Electrical Contractors and Dealers held in Decatur, Ill. In addition, the advantages to be derived by the contractor-dealers from the aid of such outlets was pointed out.

This letter is substantially as follows:

Chicago, Illinois, June 17th, 1919.

Dear Mr. Lloyd:

Confirming conversation with you of last evening relative to the Illinois State Association of Electrical Contractors and Dealers meeting at Decatur, I would appreciate it very much if you will bring to the attention of the contractors the importance of getting that body of men to feature the proper equipment of the home with special reference to installing adequate number of baseboard and wainscoting outlets so as to provide the facilities for the use of appliances.

Special reference should be made to the importance of proper electrical equipment for the bath room for the use of appliances. Although it is not generally known, the hair dryer, vibrator, curling iron, fan, and heater are valuable adjuncts in the bath room. In order to utilize such appliances it is only necessary to have one or two wainscoting outlets.

This matter is of vital interest to the contractors as it directly adds to the volume of their business and a concerted effort on the part of all contractors to exploit outlets will undoubtedly gradually create a greater demand not only from those whose homes are not wired but also from existing customers.

In line with this idea the Commercial Section of the N. E. L. A. in its activities is planning to get the manufacturers of appliances, accessories and other appurtenances used in home equipment to include in their advertising reference to an illustration of the baseboard receptacle.

This matter has been brought to the attention of the Edison Electric Appliance Company which company at present only illustrates appliances with the dead end of the cord.

The idea is to show both ends of the cord. The matter has also been brought to the attention of the Cutler Hammer Company. Both companies are showing considerable interest.

If this is taken up in a big way and we ask all the manufacturers who do national advertising to cover this feature in their advertising, I believe that after a reasonable period of time the public will be subconsciously impressed with the idea of proper wiring.

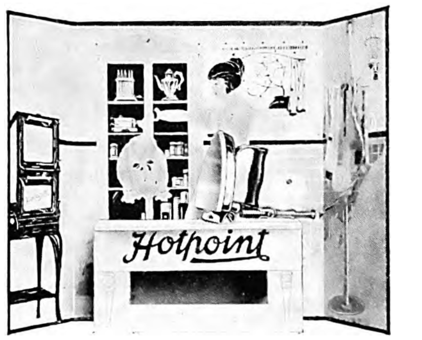
It is self evident that it is to the mutual advantage of everyone engaged in the electrical industry. It follows as a matter of course that the manufacturer will sell more appliances, the contractors will do more wiring, the accessories manufacturers will turn out a larger volume of products and last but not least, the central-station company will enjoy added revenue, and probably most important of all, it will make it easier to sell merchandise.

I have already spoken of this matter to Mr. L. H. Lamont, of Lamont & Company, 9 S. Clinton Street, Chicago, who is a member of the Commercial Section Executive Committee.

Yours very truly,

(Signed) JOHN G. LEARNED.

In order to realize the best results from this campaign however, the fullest co-operation must be received from the electrical contractors and dealers. As stated in the letter the installation of more outlets will result in added profits for wiring which should be of interest to the contractor. In addition, as the general trend at present is for contractors to conduct retail stores in connection with their wiring business, the fact that it will make it much easier to sell appliances should be especially attractive at this time.



Reproduction of May Display of Hotpoint Irons Showing Appliance Connected to Convenient Wall Outlet.

The co-operation of the contractor-dealer can be rendered in two ways. First, by an earnest effort to have a sufficient number of outlets included in the original wiring specification. It is a well-known fact that the installation of outlets is much more expensive if it is done after the building is completed or as an extra. Furthermore, it is much easier to persuade the owner to have outlets installed at this time. Secondly, contractors and dealers should follow out the plan suggested in their stores, windows and local advertising by displaying appliances connected to such outlets and encouraging their installation in every possible way.

In the accompanying illustration is shown one of the recent window displays furnished to its dealers by the Edison Electric Appliance Co., Chicago, featuring the Hotpoint electric iron. As illustrated the convenience of the iron is more clearly brought out by showing the cord so connected that it will not interfere with its use.

THE CHANNELS OF DISTRIBUTION FROM MANUFACTURER TO CONSUMER.

Paper Presented Before the New York State Association of Electrical Contractors and Dealers at Saratoga Convention.

By Samuel Adams Chase

Special Representative, Westinghouse Electric & Manufacturing Co.

The channels of distribution in the electrical industry are indefinitely marked with the trade beacons of trade organizations, proper trade differentials and a proper code of practice and ethics, supported by absolute knowledge of what each of these beacons mean to the captains of this industry and reminds one of a mariner who endeavors to pilot a ship through a river which was not clearly marked with safety beacons.

In considering this subject three important factors should properly enter into the discussion, the economic distribution, effective distribution and adequate distribution. The product to be distributed is made up principally of merchandising or resale electrical appliances and supplies and does not include, in its bills of lading, lighting or power apparatus.

The various channels of distribution in the past from the manufacturer to the consumer may be divided into the following groups: By the manufacturer direct; by the jobber-wholesaler; by the manufacturer's agent; by the central station; by the hardware merchant; by the dry goods store; by the drug store, and in some instances by various other merchants not strictly in the electrical supply business; and by the contractor-dealer.

The manufacturer has frequently made the mistake in the past of being allured by the temptation to obtain the middleman's profit and has taken small orders direct from the consumer, at an apparent profit. He has learned by costly experience however, that this so-called profit is wiped out by the cost of obtaining and handling the orders and the result is not only a net loss in money but a disturbed and unhealthy condition in the trade. It has in some instances taken years of experience to teach the manufacturers the wisdom of a policy of selling their merchandising product to the consumer through the middleman, recognizing the service rendered by the jobber and the contractor-dealer.

He has, in some instances, chosen the direct route to consumers in the past due to the uneconomic, ineffective and inadequate distribution through other channels and a hesitancy on the part of the middleman to create a sufficient demand for the goods manufactured and although a definite sales policy has been adopted by some manufacturers of selling direct and through the middleman at the same prices, their direct sales exceed all others by a large percentage notwithstanding the local influence of the middleman.

It is safe to assume, however, that the average manufacturer will welcome the day when it will be possible to economically and efficiently distribute his merchandising product exclusively through the electrical jobber and retailer. But, these channels are not yet deep or broad enough or sufficiently safe and efficient to warrant any manufacturer with a large sales organization to sell exclusively through them.

The jobber or wholesaler in the past, and in some instances at present, did a retail business in addition to the wholesale business and, in some cases sold to consumers without recognizing, in the form of a differential, the service rendered by the contractor-dealer. This practice is not only unethical but demoralizes the contractor-dealer's business to such an extent that it makes that class seemingly distrustful and quite naturally has a tendency to prevent his engaging in the retail business, hence retarding sales and expansion. In addition the jobber of the past has been somewhat like many manufacturers' agents and has shipped an order calling for a miscellaneous lot of goods direct from the various manufacturers because of not carrying a sufficient stock in his warehouse, causing delayed and expensive shipments. The jobber of today however, assembles all these goods in his own warehouse and distributes complete, in one shipment, frequently the same day the order is received, which is of great advantage to the contractor-dealer. Therefore, the jobber can be the natural, economic and efficient channel of distribution from the manufacturer to the contractor-dealer.

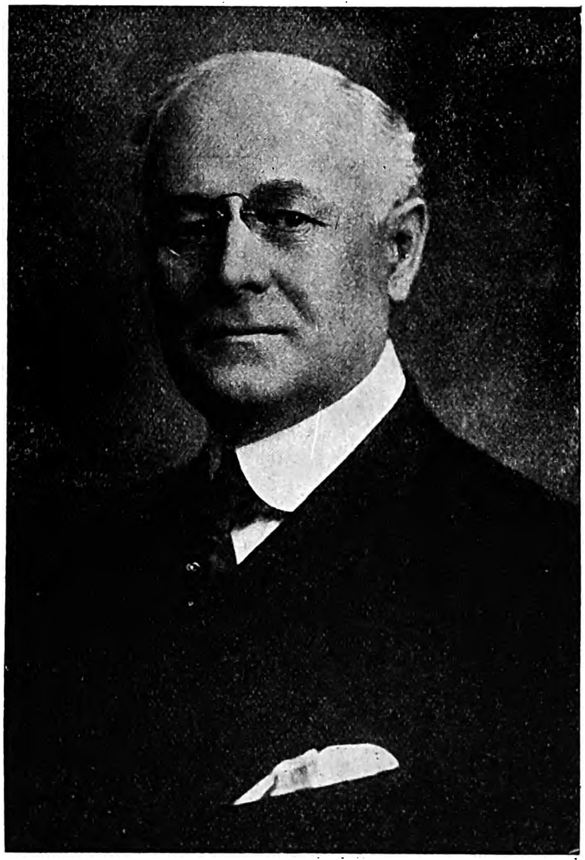
The manufacturers agents' policies vary. Some carry a small stock and ship and invoice customers. Others carry no stock and are simply order takers for the manufacturer and some sell indiscriminately to jobbers, contractor-dealers, and consumers, and should in reality be classed as salesmen for the manufacturer.

The central stations have been pioneers in the sale of and distribution of incandescent lamps and that channel was marked with beacons of free renewals and cut prices, alluring the industry not to a haven of safety but to a rock-bound coast of disaster. Now, the channel has changed to the jobber, contractor-dealer and central station, with the percentage clearly marked with beacons of ethical merchandising and intensive selling, producing absolute fairness in competition between the competing groups—and the contractor-dealer with a well-located attractive retail store now plays an important part in the channel of distribution of lamps from the manufacturer to the consumer. The flat iron, washing machine and vacuum cleaner and other household appliances were also introduced principally by the central station and it is believed that the central station on account of its organization, prestige, financial responsibility and desire to add kilowatts to its lines, will always be the logical pioneer and pilot the way for the jobber and contractor-dealer. It would be very unfortunate to the manufacturer and the consumer if the central station should go out of the retail business properly conducted on an ethical basis, for central stations will always carry the introductory or development expense of placing new devices on the market.

The hardware, dry goods, drug store, and kindred merchants have probably done more to advertise electrical merchandising products than other distributors, but in their advertising, like some central station advertising, the principal story is cut-prices. With their recognized business ability attractive stores and display windows and unquestionable financial standing, however, the call of this siren has been so alluring that it has wrecked many a manufacturer's ship in the channel of distribution to the consumer.

Each of these groups, however, creates and obtains a certain amount of business which ordinarily could not be obtained by strictly electrical concerns principally because these merchants make it easy for the housewife to obtain electrical appliances. Their stores are attractive, located in the shopping district frequented by ladies and in charge of an efficient sales organization, and they will continue to increase their electrical departments and sales and will attract the manufacturer as one of the efficient and economic channels of distribution, unless the contractor-dealer becomes alive to the situation and the necessities of the public and adopts such methods.

The beneficial results of a plan of scientific merchandising, practical trade co-operation and organization as advocated by Mr. Goodwin and which has been so ably supported by the electrical press, manufacturers, jobbers and central stations, will unquestionably result in making the specialized electrical retailer the dominating channel of distribution from the manufacturer to the ultimate consumer. The contractor-dealer has not until recently become a merchant for the reason that apparently all classes in the industry have looked upon him as a necessary evil rather than an economic necessity. All other classes in the industry have been cultivated to a high degree but the contractor-dealer until recently has been allowed to drift, unaided, uncultivated, and looked upon as a parasite, superfluous in the channel of distribution and, rudderless, without a beacon light to guide him, has been wrecked on the rocks of commerce. Because of these facts, and realizing there was no stability to the prices of merchandising appliances or wiring devices, he has not taken advantage of the opportunity presented and opened a sufficient number of attractive retail stores. The channel of distribution from the manufacturer to the consumer *via* the electrical dealer route therefore, has made it difficult rather than easy for the housewife to purchase electrical appliances.



Samuel Adams Chase.

Channels of distribution like rivers cannot be forced from the manufacturer to the consumer through uneconomic channels. However just as the channels of navigation in a river change from time to time due to natural elements which may be changed through the medium of engineering talent and modern machinery, so may the channels of distribution of electrical merchandise be changed by the application of scientific merchandising methods directed by the best thought and activity of the contractor-dealer. The author is firmly convinced that by an aggressive sales policy in co-operation with the jobber, coupled with active interest in his association and the most friendly relations with manufacturers, central stations, consulting engineers, builders and architects, the contractor-dealer will gradually become a dominant factor in the distribution of materials.

It is to be hoped that the time will come when every contractor-dealer will be a member and attend all state conventions and at these meetings representatives of manufacturers, jobbers, central stations, architects, engineers and the press will be included so that all can appreciate and understand the problems of the others, thereby establishing friendly and ethical relations, and facilitating distribution.

The trade seeks the channel of least resistance. The better business man the contractor-dealer develops to be, the more prominent the location of his store, the character of his store, the support which he gives to his trade associations, the manner in which he conducts his trade association, the character of officers of his association, and the conduct and manner of presenting his trade problems to the manufacturer or jobber all tend toward removing barriers and resistance and aid in directing the flow of trade through the contractor-dealer channel. The manufacturer is faced with a choice of channels for the distribution of his product. In one channel is the palatial department store, well managed, with unquestionable credit standing; in another, the central station and the jobber, and in another the contractor-dealer, who in the past has not always appealed to him in a favorable light. With the methods now being employed, however, with attractive retail stores, located conveniently for the buying public, intensive sales methods, improvement in organization, proper presentation of problems through able committeemen presenting forcible rather than arbitrary arguments, the contractor-dealer is every day commanding a higher respect from manufacturer, jobber and central station, and is causing them all to think, and to think hard, which must result, if they continue along these constructive lines, in causing an increasing percentage of business to flow from the manufacturer through the jobber-contractor-dealer channel.

In conclusion it is suggested that in the channel of distribution in which the contractor-dealer navigates, the beacons be labeled—organization, co-operation, ethical merchandising policies and determination. With these slogans properly applied there can be but one answer and that is the contractor-dealer ship will be the flag ship and lead the squadron through the channel of distribution from the manufacturer and jobber to the consumer.

New Appliances

Special Ampere-Hour Meter to Insure Proper Charging for Tractors and Trucks—Fan to Promote Kitchen Comfort

Locomotive Type Ampere-Hour Meter for Truck, Tractor and Locomotive Battery Charging.

The experience of the past few years in the operation of storage-battery trucks, tractors and battery mine locomotives has clearly demonstrated that the chief problem in the operation of these devices is the problem of the storage battery. Accordingly, the ampere-hour meter, which is the only device that automatically gives a true indication of the state of charge of the storage battery at all times and can be made to automatically terminate the charge at the proper time, is of special importance in this connection. A new locomotive type ampere-hour meter has just been designed by Sangamo Electric Co., Springfield, Ill., in order to meet the severe requirements as to overload and vibration experienced in this particular service.

Ampere-Hour Meter Control.—The ampere-hour meter, when installed permanently in the storage-battery circuit on the truck, tractor or locomotive, registers every ampere-hour which the battery discharges in driving the vehicle, and since the total battery capacity is indicated by the red "Empty" hand on the meter, the black hand indicates the remaining capacity left in the battery. The operator then knows at all times how much farther he can run the truck. When the battery is later put on charge the ampere-hour meter registers as the charge proceeds, operating in a direction reverse from that of discharge. When the battery has been fully charged the meter will register zero and make a contact within the meter which trips the circuit-breaker in the charging circuit.

Automatic Charging.—No battery is 100% efficient. More charge must be given than was taken out on the previous discharge, so there must be a certain amount of excess charge each time the battery is charged. This feature is automatically provided for in the locomotive type ampere-hour meter by means of a variable-resistor device, which causes the meter to run slower by any desired percentage on charge than on discharge for equal current flow. This automatically provides that the battery will be given any desired percentage of overcharge, for by the time the meter indicating hand gets back to the full charge position, all of the previous discharge plus a certain percentage of overcharge (depending upon the setting of the variable-resistor element) will have been put back into the storage battery. This feature is entirely automatic, and once the resistor has been set at the desired percentage of overcharge, no further attention need be given the device.

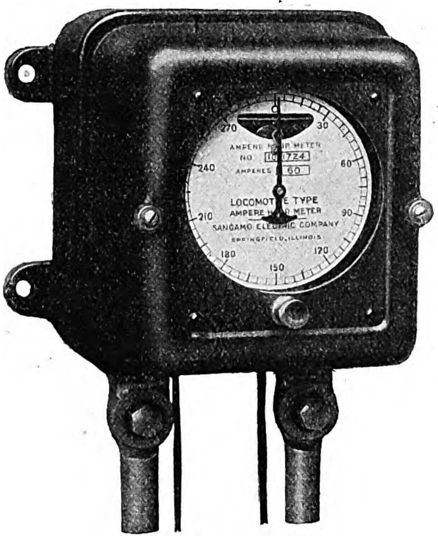
Special Features of Locomotive Type Meter.—The locomotive type meter, which has been especially designed to meet the severe requirements of mine locomotive and industrial truck service embodies several distinct improvements over previous Sangamo ampere-hour meters.

1. *Overload Capacity Increased.*—The locomotive type meter will carry 300% load continuously and 500% load for 3-minute periods without undue heating of any part.

2. *Meter Made Dust and Moistureproof* by means of improving binding posts, terminals and soft rubber gasket in case.

3. *New Type Contact at Zero.*—This is mounted entirely back of the dial and operates on cam principle instead of lever as formerly, thereby reducing the drag on meter and increasing reliability of the action of the contact.

4. *Modified Motor Element.*—Special treatment is given to both the armature disk and armature box interior which has reduced the formation of mercury dross to about ¼ of that formerly experienced. This will probably improve the meter operation very greatly and eliminate trouble due to meters being slow on account of dross.



New Type Ampere-Hour Meter for Battery Discharge and Charge and Terminating Latter at the Proper Point.

5. *New Type Variable-Resistor Element,* which is approximately eight times as effective as the resistor element formerly used. This insures great reliability of operation and increases the range of adjustment so as to provide a maximum of 50% overcharge where desired.

6. *Reset Made Dustproof.*

7. *Lock Washers* throughout and special rugged construction combined with mercury flotation of the rotating element, making the locomotive type meter immune from vibration and loads.

Ilg Electric Household Kitchen Exhaust Fans.

Comfort is an essential to efficiency in the home as well as the factory, store or office. The kitchen in the average home is the room that is most neglected as far as provision for comfort is made therein. This is one of the reasons why many housewives do not like to cook and also why domestic servants willing to cook are steadily decreasing in number. One of the most important aids to kitchen comfort is a proper electric exhaust fan to remove the hot, humid and often malodorous air so commonly found in the kitchen, especially when the latter is located in a portion of the building where natural ventilation is difficult or impossible. Even where the winds may have access to the kitchen window and door, they are an uncertain quantity and as likely to blow the kitchen odors and smoke into the other rooms of the house or apartment as to blow them out.

The Ilg Electric Ventilating Co., of Chicago, Ill., which claims to be the largest exclusive manufacturer of electric ventilating equipment, has made a special study of kitchen ventilation as a result of which it has developed an exhaust fan especially suited for this service. This fan is small, quite neat in appearance and quiet in operation. It is easily installed in the upper portion of a window, in a transom or special wall opening. Its current consumption is low enough to permit operating on the ordinary house lighting circuits. The motor is fully enclosed as a protection against heat and grease. The latter would quickly choke up the motor, cause overheating of it and result in possible fire. Like other Ilg fans, these exhaust outfits have a patented self-cooling feature, by means of which cool air is drawn through the motor enclosure and carried off with the general exhaust. This keeps the motor windings at safe operating temperature. The air drawn through the case being clean air, the windings are kept from being choked up.

Use of these Ilg kitchen exhausters has been found to promote comfort in the cooking, since the kitchen is kept from becoming hot, stuffy and malodorous. They also prevent the kitchen odors, fumes and smoke from entering the other rooms to the annoyance of other members of the family and guests, and by withdrawing them promptly they are also prevented from smudging and otherwise spoiling wall decorations, pictures, etc.

In order to assist its dealers in the sale of this fan the company has arranged a very attractive window display. This consists of a three-panel mounting, decorated to represents a kitchen interior in which a real fan can be mounted and operated in the dealer's window.

Trade Activities

Ohio Electric & Controlling Co. Appoints Representatives —Harrison Safety Boiler Acquires Monash Equipment

Edison Electric Apliance Co., Inc., Hughes Division, has issued a circular offering to dealers stereotypes of four advertisements on electric ranges so they may tie in their local newspaper advertising with the national advertising campaign now being conducted by the company. These are furnished in single, double or triple column size and provide space for the dealers' name.

Murray Iron Works Co., Burlington, Iowa, has appointed S. C. Orrell its Chicago district sales manager with headquarters at 1215 Conway building. Mr. Orrell was for many years identified with the Chicago office of Allis-Chalmers Manufacturing Co., later becoming Minneapolis district manager for the company. Mr. Orrell will prove a valuable addition to the staff of the Murray company.

Jewell Electrical Instrument Co., 1646-50 Walnut street, Chicago, is distributing a new 72-page catalog on electrical measuring instruments, which is one of the most complet catalogs dealing with this equipment ever published. The descriptive matter has been very carefully and accurately written, giving brief and comprehensive data and information on each instrument. All portable instruments are first described and illustrated, following which is the switchboard equipment. A feature of this catalog is the very complete and convenient set of charts in which each instrument is listed with all ranges of readings and prices. All shunts, transformers and multipliers are illustrated and described. Some 12 pages are devoted to full size reproductions of instrument scales, diagrams showing shunt dimensions, drilling dimensions and series transformer dimensions.

Electric Storage Battery Co., Philadelphia, Pa., recently received from a number of its customers, letters of testimony bearing evidence of the efficiency of the industrial electric truck. One of the firms that is using an industrial truck with an "Ironclad-Exide" battery states that six men who received an average pay of 42 cents per hour have been replaced by using one industrial truck of two-ton capacity. Another informs that in addition to the saving of labor, the trucks are hauling material from one place to another in less than one-third of the time formerly taken. These are but two of thousands of similar installations where the industrial electric vehicle has proven itself to be a most efficient transportation labor-saving equipment. However, the full efficiency of any industrial truck or tractor is only realized when it is equipped with the proper make and type of battery, and in this connection the "Ironclad-Exide" has rendered admirable service.

The Industrial Electric Furnace Co., 53 West Jackson boulevard, Chicago, now owns all patents covering the Snyder electric furnace, E. T. Snyder, formerly vice-president, having left the organization, effective June 1.

Harrison Safety Boiler Works, Philadelphia, Pa., has acquired the Monash line of pressure reducing valves and pump governors, formerly manufactured and sold by the Monash-Younker Co., of New York and Chicago. The purchase includes a stock of manufactured parts and valves, drawings, patterns, trade mark and good will. The Harrison Safety Boiler Works will manufacture and market the valves under the trade name "Cochrane-Monash," and will supply repair parts for valves now in use.

Illinois Electric Porcelain Co., Macomb, Ill., has issued a new catalog on electrical porcelain insulations. This contains 24 pages, for the most part full size sections and part elevations of various forms of porcelain insulators, standard porcelain electrical parts and special porcelain. Included among these are standard and split knobs, one, two and three-wire cleats, switch bases, ceiling buttons, strain insulators, pin bases, rack insulators, exterior and interior bushings, leading-in-tubes, pole-line screw-thread insulators and standard unglazed tubes. In connection with the latter an interesting table of numbers of tubes of various sizes in the standard barrel and gross weights of various tubes in a standard barrel are given.

Cutler-Hammer Manufacturing Co., Milwaukee, Wis., has given the title "Helps in Merchandising Electrical Appliances" to a new 16-page two-colored booklet because all the 1919 advertisements reproduced in it request the public to go to the electrical dealers. Last year the company had to postpone on account of war restrictions its second national advertising campaign on the C-H Seventy Fifty switch which is used on the cords of heating devices and many other electrical appliances. For the 1919 campaign the original advertisements have been increased in size and number and additional national media are being used. Reproductions of all the advertisements which have or will appear in the *Saturday Evening Post, Literary Digest* and *Good Housekeeping Magazine* this year, are shown.

In addition, several new and interesting helps for dealers have also been provided, such as a four-color lithographed window trim, street car cards, window and wall display cards, three or four two-color booklets which are imprinted for dealers' use, colored "movie" theater slides and eight little stickers for use on letters going forth from lighting companies, dealers and jobbers, contractors and others. Besides this, there are eight newspaper advertisements, complete electros of which can be had by the dealer. These newspaper advertisements play up strongly the use of electrical appliances of all kinds and point out the convenience to be secured when such appliances are equipped with the C-H Seventy Fifty switch. They will, therefore, increase interest in the use of all makes of household electrical appliances and when used by the dealer at the time the national advertising is appearing, will help to tie-up his store with the national publicity and increase his sales of electrical appliances of all kinds.

Belden Exhibit at Telephone Convention.—One of the most interesting exhibits of the recent United States Independent Telephone Association convention at Chicago was that of the Belden Manufacturing Co., 2300 South Western avenue, Chicago. A high-speed braiding machine for braiding wire and cordage was set up and operated during the three days of the convention, showing the process of manufacturing many different types of cordage and wire with silk and cotton braids. This was a very interesting novelty to many convention visitors. A motor-driven coil-winding machine, which the company manufactures for the trade and numbers of which are used in its coil-winding department, was in operation, making numerous coils wound with enamelled wire manufactured by this company which is well known under its trade name "Beldenamel."

The Ohio Electric & Controlling Co., 5900 Maurice avenue, Cleveland, Ohio, announces the appointment of the following firms as its representatives: The Iron & Steel Equipment Co., 1502 First National Bank building, Pittsburgh, Pa.; Williams Beasley Co., 343 South Dearborn street, Chicago; Linn O. Morrow, 707 Franklin Trust building, Philadelphia, Pa.; J. W. Dopp & Co., 18 Columbia street, Detroit, Mich.; Kelly, Powell, Ltd., 403 McArthur building, Winnipeg, Can.; Wonhan, Bates & Goode, Inc., Dominion Express building, Montreal, Can.; Shook & Fletcher Supply Co., Birmingham, Ala. The company has also appointed foreign representatives as follows: Wonham, Bates & Goode, Inc., 17 Battery place, New York City, London, Paris, Havana and Rio de Janerio; Mitsui & Co., 65 Broadway, New York, Japan, China, Philippine Islands and Honolulu, and Gustdv Neilson, A. S., Christiania, Norway, Sweden and Denmark.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Rutland, Vt.—Western Vermont Power & Light Co. has been awarded a contract for furnishing electric energy for the operation of a large new plant at Fair Haven, Vt., manufacturing shirts. The plant is electrically operated throughout, and considerable power will be required for a large number of electric irons.

Boston, Mass.—In connection with the construction of a new four-story publishing building, at 240 Washington street, to be occupied by the Boston Globe Co., estimated to cost $100,000, considerable new electrical equipment will be required.

Chelsea, Mass.—Power Efficiency Corp., While building, Buffalo, N. Y., has submitted low bid to the Government, Navy Department, for the installation of the proposed heating system, etc., at the local naval station.

Gardner, Mass.—Gem Crib & Cradle Co., Main street, has recently broken ground for the construction of a new power plant at its works, to be used for factory operation. Heretofore power has been furnished by the Connecticut River Power Co.

Leominster, Mass.—Plans are under consideration by the City Council for an appropriation of $75,000, to be used for municipal improvements, including improvements in the street lighting system.

Worcester, Mass.—City Council has voted a loan of $50,000, to be used for construction work in connection with the new reservoir at Pine Hill for the waterworks system.

New Haven, Conn.—In connection with its proposed plant on Hallock avenue, the Seamless Rubber Co. will build a power plant for factory operation. The works will comprise three main buildings, each five-story, about 60x240 ft. It is said that the entire plant will cost about $1,000,000.

Waterbury, Conn.—A one-story power house, 35x60 ft., will be built by the American Brass Co. at a cost of $50,000.

Providence, R. I.—Atlantic Mills have awarded a contract to O. D. Purington & Co., Industrial Trust building, Providence, for the construction of a new three-story power plant about 46x98 ft. at its works at 120 Manton avenue. The structure is estimated to cost about $25,000.

Albany, N. Y.—Contract has been awarded to the General Electric Co., 527 West 34th street, New York, by Edward S. Walsh, State Superintendent of Public Works, for furnishing and delivering electric capstan and trolley hoists at various barge canal terminals, under Barge Canal Terminal Contract No. 113, at $14,090. Frank M. Williams, Telephone building, is state engineer and surveyor.

Brooklyn, N. Y. — Mergenthaler Linotype Co., 24 Ryerson street, has had plans prepared for alterations and improvements in its one-story boiler plant, to facilitate operations. Estimated cost $6000.

Brooklyn, N. Y.—Edison Electric Illuminating Co., 360 Pearl street, has filed plans for the erection of a new addition to its plant on 66th street, for increased capacity. Contract for the structure has been awarded to the Hamilton & Chambers Co., 1290 Broadway, New York.

Brooklyn, N. Y.—Bureau of Yards and Docks, Navy Department, Washington, D. C., is planning for a boat storage works at the Brooklyn navy yard, to cost about $45,000. The equipment will include two electric traveling cranes.

Buffalo, N. Y.—Robertson-Cataract Electric Co. will erect a six-story addition to its plant to cost $80,000.

Dansville, N. Y.—Power Specialty Co., manufacturer of steam and hydraulic specialties, is preparing plans for the erection of a two-story addition, to cost about $25,000.

Iroquois, N. Y.—Board of Managers of Thomas Indian School has awarded a contract to the Millenburg-Betz Machine Co., 110 Washington street, Buffalo, for the installation of new refrigerating equipment at the institution, to cost about $7325. Lewis F. Pilcher, Capitol building, Albany, is state architect.

Montauk, N. Y.—The Bureau of Yards and Docks, Navy Department, is taking bids on revised plans for the construction of the proposed power plant (Specification 3889) at the local naval station. C. W. Parks is chief of the Bureau of Yards and Docks.

New York, N. Y.—Considerable electrical equipment, including electric-operated traveling cranes, etc., will be installed in the new five-story building, about 125x100 ft., recently leased by Julius Blum & Co., 510-12 West 24th street, iron mouldings, etc. Extensive alterations and improvements will be made in the structure previous to occupancy by the company.

New York, N. Y.—New York Edison Co., Irving place and 15th street, has recently been awarded a contract for supplying electric service for all operations at the American Surety building, a 20-story office structure, at 100 Broadway. The structure will require current for 5000 lamps and 500 hp. in motors.

New York, N. Y.—Alpha Electric Co., Inc., 116 West 29th street, has leased property comprising about 22,500 sq. ft. of floor space at 151-155 West 30th street, for a new establishment, at an aggregate rental of $150,000.

New York, N. Y.—Reimers Manufacturing Co., 517 West 45th street, manufacturer of electric heaters, has leased property at 507-13 West 50th street, for a new establishment.

Potsdam, N. Y.—Dr. Thomas E. Finegan, deputy commissioner of education, Education building, Albany, has taken bids for the erection of a new boiler plant at the local normal school, including the installation of new heating equipment and electrical work.

Dover, N. J.—New Jersey Power & Light Co. has completed plans for the installation of new coal handling equipment at its new local plant. The company has recently been awarded a contract for furnishing electric energy for the operation of new motors installed at the municipal waterworks.

Merchantville, N. J.—Board of Public Utility Commissioners has granted permission to the Merchantville Water Co. to increase its rates for service, effective July 1.

Newark, N. J.—Murphy Heating Co. has filed notice of organization to operate at 51 State street for the production of heating devices. L. and K. Murphy head the company.

Newark, N. J. — Public Service Corp. has had plans prepared for alterations and improvements in its building at the foot of Hudson place, to facilitate operations.

West Orange, N. J.—Highland Electric Co., 10 Freeman street, has filed notice of organization to operate an establishment for general electric repair work. Frank Rotalo and A. Pettis, West Orange, head the company.

Summit, Del.—Work has recently been completed on the installation of a new electric lighting system throughout the Brandywine Summit Camp grounds, near Wilmington, and it is expected to inaugurate operations at an early date.

Wilmington, Del.—Sterling Electric Co. has filed notice with the Secretary of State of an increase in its capital from $10,000 to $100,000, to provide for general expansion.

Beaver, Pa.—Harmony Electric Co., with headquarters at Pittsburgh, has arranged plans for the merger of a number of electric light and power companies now operating in Beaver County under its present name. Application has been made to the Public Service Commission for approval.

Philadelphia, Pa.—Bids are being taken by the Niles-Bement-Pond Co., Mifflin and Meadow streets, for the construction of the proposed boiler plant at its works. The structure will be one story, about 44x60 ft.

Philadelphia, Pa.—Contract has been awarded by the Navy Department to the Enterprise Steam & Hot Water Heating Co., 600 North Howard street, Baltimore, Md., for the installation of new heating apparatus at the local navy yards.

Reading, Pa.—Metropolitan Edison Co. has recently commenced the construction of a second long-distance high-tension supply line to Lebanon, a distance of about 28 miles. The line will be equipped with insulation that will enable it to carry 66,000 volts, but operating voltage under present requirements will not exceed 33,000 volts, it is understood. The construction of this line will allow for the closing down of the generating plant at Lebanon, affording a saving in operating expenses of about $21,000 annually.

Titusville, Pa.—Titusville Light & Power Co. has arranged for the issuance of bonds for $15,000 to provide for general expansion. Notice has been filed with the Public Service Commission.

Zelienopel, Pa.—Large quantities of electrical equipment will be required in connection with the proposed construction of the new plant of the Universal Rubber Co., estimated to cost about $300,000. It is understood that the company is planning the construction of a second unit at a later date.

Cumberland, Md.—Western Union Telegraph & Cable Co. in conjunction with the Cumberland Division of the Baltimore & Ohio Railroad Co. has commenced work on the laying of underground cables for a new electric signal system, telephone and telegraph wires from the Queen City depot to the Viaduct tower, a distance of about three-fourths of a mile. The work is estimated to cost about $40,000.

Elkton, Md.—Town Council has recently completed negotiations with the receivers of the Maryland Water Co. for the purchase of its waterworks for a consideration of $35,375. It is understood that in connection with municipal operation of the plant, improvements will be made.

Hagerstown, Md.—Hagerstown & Frederick Electric Railway Co., operating five steam power plants and four hydroelectric stations, is negotiating with the city officials for the furnishing of electric current to the city for lighting purposes and for private utility by citizens. It is held by the company that this arrangement will afford an annual saving of a minimum of $10,000.

Lexington, Va.—Plans are being prepared by the Virginia Military Institute for the installation of two new 500-hp. boilers at the plant of the institution, estimated to cost $15,000. Carneal & Johnston, 707 Chamber of Commerce building, Richmond, Va., are engineers.

Norfolk, Va.—Columbia Peanut Co. desires prices on 80 to 100-hp. boilers and Corliss engines.

Clendenin, W. Va.—Kanaelk Coal Co. has had plans prepared for the erection of a new power plant at its local properties, in connection with other work. W. W. Whyte is president.

Taylorsville, N. C.—Plans are in process of formation by the Alspaugh Light & Power Co. for the construction of a new hydroelectric plant to be located about five miles from Taylorsville. The works will include the erection of a concrete power house, with dam, and a five-mile transmission system. T. C. Alspaugh is interested in the company.

Arlington, Ga. — Baker County Power Co. is understood to be considering plans for the construction of a new dam on Natchanny Creek, in connection with its proposed hydroelectric development.

Bowling Green, Fla.—Prices on 150-hp. boilers, 50-hp. engines and 50-kw. generators are wanted by the Bowling Green Manufacturing Co.

DATES AHEAD.

National Association of Electrical Contractors and Dealers. Annual convention, Milwaukee, Wis., July 15, 16 and 17. General manager, William H. Morton, 110 West 40th street, New York City.

Ohio Electric Light Association. Annual meeting, Cedar Point, Ohio, July 15-18. Headquarters, Breakers Hotel. Secretary, D. L. Gaskill, Greenville, Ohio.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 19-21. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., September, 1919. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston block, Seattle.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

NORTH CENTRAL STATES.

Hamilton, Ohio.—An electric power plant is to be established at the Rockdale dam to furnish power for the Hamilton Furnace Co., which will double the capacity of its present plant.

Toledo, Ohio—The Fisher-Storey saw mill, recently destroyed by fire, will be rebuilt. The plant is to be motor driven, power being supplied from a power plant built as a part of the mill.

Fort Wayne, Ind.—Pennsylvania Railroad will erect new air compressor in its power plant. The new apparatus will have a capacity of 2700 ft. per minute. Address Assistant Foreman Hosterman.

Gary, Ind.—Dorman and Sykes Auto Sales Co. will build a $100,000 building, three stories, which will be the second largest business block in Gary.

Gary, Ind.—Revescz Home Building Co. will erect 16 apartment houses at a cost of $225,000, two six-apartment buildings to be erected immediately.

Indianapolis, Ind. — The Indiana Public Service Commission has authorized the Union Traction Co. of Indiana to issue $150,000 worth of three-year promissory notes, dated July 1, 1919.

Indianapolis, Ind. — Indianapolis Belt Railroad Co. will expend $20,000 at the Indianapolis stock yards, the first important improvement being the erection of a new building, 200x300 ft.

Indianapolis, Ind. — Indianapolis Cordage Co. will erect one-story warehouse, 140x200 ft., at cost of $30,000.

Richmond, Ind.—E. W. Steinhart Co., Indianapolis, will erect four-story concrete building to cost $125,000.

South Bend, Ind. — Studebaker Corp. has taken a permit for the construction of $700,000 factory building, 192x504 ft.

South Bend, Ind.—American Home & Investment Co. will erect forty-six new houses in this city.

Carlinville, Ill.—Macoupin county board of supervisors will install electric lights throughout the court house. Address Q. H. Bates, supervisor, Carlinville, Ill.

De Kalb, Ill.—De Kalb-Sycamore Electric Co. will erect a large cooling tower 80 ft. in height, and 12 to 15 ft. in diameter.

Mt. Auburn, Ill.—Wurl Electric Co. has applied for a permit to install an electric lighting system in Mt. Auburn, Ill., and to sell $5000 of its capital stock.

Elwood, Ind.—Sellers Kitchen Cabinet Co. has begun construction of four-story building, which will make the seventh building for this company. The State Construction Co. of Indianapolis has the contract. The new building will be of brick and structural steel.

Evanston, Ill.—The Illinois Public Utilities Commission has denied the right of the Chicago, Fox Lake & Northern Electric Railway to construct a suspended monorail railway between Evanston and the village of Palestine. The original petition was denied some months ago and the petition to reopen the case has also been denied. The company is authorized to cease taking subscriptions and from selling its one-year 7% gold notes.

Palmyra, Ill.—An order entered by the State Utilities Commission gives the Palmyra Light, Heat & Power Co. the right to construct and operate a transmission line from Palmyra to Waverly, and which is to extend to Modesto, for the purpose of furnishing electric light to consumers along the proposed route. In addition the company is given the right to issue first mortgage bonds in the aggregate of $8,000. Address Lewis M. King, president.

Petersburg, Ill.—An electric line is being provided between Springfield and Rushville by the way of Petersburg and Chandlersville. John Rosenwienkyle, 2154 North Racine avenue, Chicago, is promoter.

Urbana, Ill.—The Urbana board of local improvements has decided to resurrect the ornamental lighting proposition once started for the southwest part of Urbana, including the territory south of University avenue and west of Market street. City Engineer A. M. Danelly is now at work on plans for the system which is expected to cost about $100,000.

Villagrove, Ill.—The failure of the Central Illinois Public Service Co., to furnish power has started the organization of a company to build power plant. Address city clerk.

Adrian, Mich. — United Electric Manufacturing Co. has acquired the site of the Lion Motor Co. plant, on which it proposes to erect a $100,000 plant.

Lansing, Mich.—The question of issuing $65,000 in bonds for extending the light and water power service is being considered by the local authorities.

Appleton, Wis. — Wisconsin Traction Co., will extend its line to nearby towns. Work on the extensions to Hortonville has been commenced.

Saginaw, Mich. — The council has been petitioned to have street cars lines extended to new factory district. Address city clerk.

Stanwood, Mich. — Stanwood will have an electric lighting system. Six men of the town have organized a company and will put up a plant adequate to the needs of the town. Wires will be installed all over the town, both for residence and store use. The company was organized by M. D. Crane, E. L. Smith and others.

Davenport, Iowa — Linograph Co. will erect the first unit of its factory building to cost about $100,000. The new building will be 65x150 feet, four stories and basement. It is the first of three units which will eventually be connected with a corridor.

Newton, Iowa—Plans are in progress for electric plant. Archer & Stevens, 609 New England building, Kansas City, Mo., architects. Additional lights will be installed. Address city clerk.

Fulton, Mo.—Board of Managers of Westminster College has had plans prepared for the construction of a new electric power and heating plant at the institution, estimated to cost $30,000. Contract for erection has been awarded to Oscar Thomas, Sedalia, Mo.

Kansas City, Mo.—The $500,000 bond issue for extensions at the municipal light plant was ratified at a recent election. Extensions which will almost double the capacity of the plant will be made within a few weeks. The estimated cost of the improvement will be $407,000.

Wichita, Kans.—Another unit is to be built to the Kansas Gas & Electric Co.'s plant at Third and Kelley streets at a cost of $500,000. Plans for the building have been prepared and the contract for its construction has been awarded for the Phoenix Utility Co.

Lincoln, Neb.—Secy. Danielson of the state fair branch has petitioned the council to extend the city lights to the state fair ground.

Omaha, Neb. — Nebraska Power Co. has filed a first mortgage for $5,600,000, the entire issue having been bought by the Guaranty Trust Company of New York. Part of the proceeds of the mortgage will be used to pay off $2,000,000 of bonds now outstanding and the balance will be used to make improvements.

Madison, S. D. — Bonds to the amount of $100,000 have been voted for an electric light plant.

SOUTH CENTRAL STATES.

Louisville, Ky.—Fifty houses at a cost of $200,000 will be constructed in Louisville by the Consolidated Realty Co. The houses will average between $4000 and $16,000 each. It is estimated that 2500 houses are needed in Louisville.

Louisville, Ky.—L. C. Lashment, secretary and treasurer of Wadell & Son, engineers of New York and Kansas City, has arrived in Louisville to begin construction on the new electric railway which will connect Frankfort and Shelbyville. The last connecting link has been surveyed and it is planned to begin construction so that the road will be in operation by Jan. 1, 1920. A plan to bridge the Kentucky river at Frankfort has been abandoned and the present plan is to use a bridge already in use over this stream.

Louisville, Ky.—O'Connor Realty Co. will erect two-story concrete garage, 60x244 ft., to cost $50,000.

Columbus, Miss.—The council after hearing and carefully considering a report on the condition of the water plant by an expert engineer decided to purchase two auxiliary electrically driven centrifugal pumps. It is estimated the new equipment will cost $7000. Address mayor.

Alexandria, La.—$40,000 in bonds has been voted to improve street railway. Address mayor.

New Orleans, La.—The Navy Department is arranging for the construction of a large new power plant at the local Government site. It is understood that the proposed plant with equipment will cost in excess of $250,000.

New Orleans, La.—Plans are under consideration by the Board of Managers of the Charity Hospital for the construction of a large new power plant at the institution, estimated to cost, with equipment installation, about $90,000.

Kingsport, Tenn.—Holston River Power Co., Johnson City, recently organized, plans the construction of hydroelectric power plants on the Holston river, near Kingsport, to cost about $3,000,000. The company proposes to furnish electric power for industrial operations and other service at Kingsport, Johnson City, Bristol and other points.

Petersburg, Tenn. — City council has arranged for the issuance of bonds for $15,000 to provide for the municipal lighting system. G. C. Hart is mayor.

Conway, Ark.—Plans are being prepared by the city for extensive improvements and extensions in the municipal electric light plant. Estimated cost $50,000.

Fort Smith, Ark.—The Commonwealth Public Service Corp., which purchases electricity from a local company to supply all towns between Van Buren and Clarksville with power and light and which also supplies several coal mines in Franklin and Johnson counties with power, will erect a large central power station in Johnson county, in the vicinity of Clarksville. The plant will cost approximately $200,000. Steam turbines will be used to generate the power.

Afton, Okla.—City council has approved the issuance of bonds for $10,000 to provide for improvements and extensions in the municipal lighting system.

Comanche, Okla.—City voted $35,000 bonds for electric and water plant improvements . Address the mayor.

Newkirk, Okla. — Bonds to the amount of $185,000 have been voted by the City Council, a portion of the proceeds to be used for extensions in the municipal lighting system.

Abilene, Tex. — American Public Service Corp. will construct units of electric light plant to cost about $350,000.

Ennis, Tex.—The city contemplates installing an electric light plant. Address mayor.

Houston, Tex.—Mack Oil & Water Well Screen Co., Kress building, proposes to build a new plant, consisting of three reinforced concrete buildings, 100x200 ft., 75x100 ft., and 30x50 ft., at an estimated cost of $200,000. Much of the equipment will be operated by individual electric motors. J. O. Mack, manager.

San Antonio, Tex.—The council is preparing to expend $25,000 for fire and police alarm system. Address Mayor Bell.

WESTERN STATES.

Havre, Mont.—The Montana Public Service Commission in an order recently issued authorized the Montana Power Co. to discontinue service and abandon operation of its heating plant at Havre.

Sildix, Mont.—Amazon-Dixie Mining Co. will install an electric power plant in the near future. The power line will in all probability be run from Mullan. The property is a silver-lead product and has been doing extensive development work for some time.

Salt Lake, Utah—Lafayette Hanchett, representating the Dixie Power & Light Co., accompanied by Manager Woodhouse of the company appeared before the state road commission to continue negotiations looking to construction of an electric power line along the route of the Arrowhead trail, between St. George and Cedar City. The company seeks a way by which the state could undertake to construct the pole line and the company would furnish energy at the wholesale rate, to operate the mixers, rock crushers, pumping station, etc.

Mullan, Idaho—Amazon-Dixie Mining Co., at Sildix, Mont. about 11 miles from Mullan, Idaho, will install an electric power plant in the very near future. The power line will in all probability be run from Mullan.

Roseburg, Ore.—William Pellman, owner of the Roseburg light and water plant, is inspecting the properties with a view of making extensive improvements. The pumping and power plant will be improved and the entire system put in shape to accommodate Roseburg's increasing demands.

Kelso, Wash.—The contract for the new brick substation to be built in Kelso by the North Coast Power Co. has been let to N. A. Strand, Kelso, and construction work will be started immediately. The company is now rebuilding the line from Kelso to Kalama.

Tacoma, Wash.—The city will buy the Lake Cushman power site and build thereon a hydroelectric plant if the proposed bond issue of $300,000 is authorized at a special election to be held in July.

Glendale, Cal.—Bonds have been voted to improve water system, electric equipment will be purchased. Address city clerk.

PROPOSALS

Motor-Driven Ladder Truck.—Bids will be received until 10 a. m., July 11, by the Board of Public Works, Seattle, Wash., for one motor-driven 75-ft. automatic aerial ladder truck, two 100 and two 800-gal. capacity combination motor pumping engines and hose cars.

Lighting Fixtures.—Bids will be received at the office of the supervising architect, Treasury Department, Washington, D. C., until July 16 for installing lighting fixtures in the south building. Hygienic Service, United States Public Health Service, Washington.

Power Plant.—Bids will be received by the Water, Light, Power and Building Commission, Wells, Minn., until July 10 for the erection and completion of power plant building, concrete reservoir, and furnishing and delivering power plant equipment, in accordance with the plans and specifications of the Charles L. Pillsbury Co., engineers, 813 Metropolitan Life building, and Tyrie & Chapman, architects.

Electric Light System.—On July 11 bids for labor and materials required in the construction of an electric lighting system for the village of Church's Ferry, N. D., will be received, according to the plans and specifications which are on file in the office of H. A. Moe, village clerk, and also in the office of Earle D. Jackson, St. Paul, Minn. The work is divided into two parts, consisting of a brick and tile power house and furnishing and erecting two oil engines, necessary piping and accessories, two three-phase, 60-cycle, 2300-volt alternators with exciters, switchboard, etc., and furnishing and erecting poles for the electrical distribution in the village.

Electric Work.—Bids will be received by the supervising architect, Treasury Department, Washington, D. C., until 3 p. m., July 25, for furnishing materials for the construction of the United States Post Office, at Dawson, Ga., including materials for concrete, reinforced concrete, stone, granite, brick, structural terra cotta, structural steel, miscellaneous iron and steel work, composition roofing, slate roofing, sheet metal work, skylights, plastering, interior marble, sanitary slate, lumber, millwork, painting, glazing, hardware, plumbing, heating, electric work, etc., in accordance with drawings, specifications and bills of quantities attached thereto, copies of which may be obtained from the custodian of site at Dawson, Ga., or at the above office, in the discretion of the acting supervising architect. James A. Wetmore, supervising architect.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number

Electrical Supplies (29,748).—Drugs, chemicals and kindred lines; engineering and building materials, such as iron, steel, metals, heavy hardware, and machinery; electrical supplies for light, heat and power service, and for telephone and telegraph service, are required by a firm in Norway. Payments to be through New York and Norwegian banks. References.

Electrical Machinery (29,741).—The purchase of tubing for high pressure turbines and electrical machinery of all kinds for developing waterfall power is desired by a firm in a consular district of Spain. Quotations should be given f. o. b. New York. Terms, cash against documents. Correspondence may be in English. Reference.

Electric Power Plant (29,759).—The municipality of a city in Greece desires to receive proposals until Sept. 11, 1919, for the installation and operation under contract for a period of years, of an electric plant to furnish light and power to the city and its surroundings. Further information and terms of contract may be had on application to the Bureau or its district offices.

Motors, Dynamos, Electrical Apparatus (29,784).—An agency is desired by a manufacturer in Spain for the sale of cranes, elevating apparatus, gasoline, kerosene and crude-oil engines; mining machinery, machinery for the construction of public works; steam engines, electric motors, dynamos and electrical apparatus and supplies; complete material for aerial cableways; steel cables for traction and elevation; agricultural machinery and tractors. Correspondence should be in Spanish. References.

Electric Lighting Appliances (29,812).—The purchase and agency are required by a firm in Australia of all motor requisites, accessories, tires, cars, etc., novelties and specialty lines, electric lighting appliances for households, etc. Terms, cash against documents or 90 to 120 days after sight; also consigned stock to be paid as sold. Reference.

Electrical Goods (29,814).—A merchant from Peru who is in this country desires to be placed in communication with firms in view of securing agencies for the sale of electrical goods, agricultural machinery, hardware, etc. Reference.

Electrical Materials (29,815).—A wholesale dealer in Belgium desires to purchase and secure agencies for the sale of electrical materials of good quality. Correspondence may be in English. Reference.

Metal Filament Lamps and Insulated Cables (29,823).—The exclusive agency from manufacturers for the sale in India, Burma, and Ceylon, of electric metal filament lamps, ordinary and half watt, and electric insulated cables, is desired by a company in India. Reference.

Ice-making Machinery (29,809).—Ice-making machinery to be driven by oil engines or electric motors of 220-volt alternating current, suitable for manufacturing three tons of ice per 24 hours, is desired by a man in Costa Rica. Quotations should be given c. i. f. destination. Correspondence should be in Spanish. Payment, cash against documents.

Electric Vacuum Sweepers (29,810).—The purchase of electric vacuum sweepers is desired by a firm in Canada. Quotations should be given f. o. b. place of shipment. Terms, cash payment. To be shipped all rail. References.

INCORPORATIONS

Brooklyn, N. Y.—William C. Chapman & Co. Capital, $5,000. To manufacture electrical specialties. Incorporators: J. D. Murphy, W. C. and A. A. Chapman, 166 Brooklyn avenue.

Orange, N. J.—Wethling-Bakely Co. Capital, $100,000. To manufacture electrical appliances, etc. Incorporators: Edward Bakely, Livingston; and H. D. Wethling and A. D. Seymour, Orange.

Dover, Del.—Saw Tooth Power Co. Capital, $300,000. To operate a plant for the generation and distribution of electric energy. Incorporators: P. B. Drew, H. E. Knox and S. E. Dill, Wilmington.

Personal

Elliott Reid Made Sales Manager—C. McKew Parr Back from National Service — George Lockwood Passes Away

BENJAMIN C. PAGE has been appointed to the position of superintendent of the Sheffield plant of Fairbanks, Morse & Co., Three Rivers, Mich.

ALFRED M. BARRETT, Flushing, Brooklyn, N. Y., has been appointed Deputy Public Service Commissioner by Lewis Nixon, Public Service Commissioner, New York.

F. F. WINFREE has been appointed manager of the Sandpoint, Idaho, division of Mountain States Power Co. Mr. Winfree was formerly connected with the Richmond (Cal.) division of Western States Gas & Electric Co.

J. H. MORGAN, who recently resigned as manager of the local telephone exchange, has become associated with the Western Electric Co. installing farm lighting plants, with headquarters at Bentonville, Ark.

ELLIOTT REID, assistant to general manager of the Westinghouse Lamp Co., New York, has been promoted to the position of sales manager, effective July 1. In his new capacity Mr. Reid will be responsible for the commercial activities of the company in both large and miniature classes of lamps in domestic territory.

CLIFFORD M. HOLLAND, divisional engineer of the Public Service Commission, New York, has been appointed chief engineer to superintend the construction of the New York-New Jersey vehicular tunnel, estimated to cost about $12,000,000, by the New York State Bridge & Tunnel Commission, with headquarters at 115 Broadway.

C. MCKEW PARR, general sales manager for the Hart & Hegeman Manufacturing Co., Hartford, Conn., has rejoined the company after a year and a half in the national service. He was connected with the bureau of exports of the War Trade Board at Washington, and later was appointed a special representative of the Board with a commission as special assistant of the Department of State. He was also appointed vice consul at Las Palmas, Canary Islands, and at Barcelona, Spain, having also had missions in France and England.

LEONARD F. FULLER, chief electrical engineer of the Federal Telegraph Co., has resigned to become assistant manager of the Ohio Insulator Co., with headquarters at Barberton, Ohio. Mr. Fuller has been associated with the Federal Telegraph Co. during the period in which the Poulsen arc has taken a leading place in long-range radio communication, and much of the improvement in recent years contributing to their success is attributed to him. Mr. Fuller recently received the degree of Ph. D. from the Stanford University for his work in magnetic circuits in arc generators.

L. W. SCHNITZER, of the Ingersoll-Rand Co., is now manager of the pneumatic tool department of the company at Chicago.

H. W. STEELE, for five years superintendent of the gas and electric departments, El Reno division of Oklahoma Gas & Electric Co., has been appointed general manager of the gas and electric departments at Muskogee. Earl James of the Oklahoma City division of the company will succeed Mr. Steele at El Reno.

W. A. PIXLEY, general auditor of the Nebraska Telephone Co. and of the other companies of the Bell group having their headquarters in Omaha, Neb., has resigned and will devote his entire time to the Truck and Tractor Corporation of Omaha, of which company he is vice-president and general manager. Mr. Pixley has been with the Nebraska Telephone Co. for 27 years, during 14 years of which he has been auditor. Mr. Pixley has taken financial interests in the Truck & Tractor Corp. of Omaha. He is succeeded by F. L. Devereux of New York, formerly auditor of the long lines department of the American Telephone & Telegraph Co.

MAJ. J. B. JACKSON, after two years in the national service, has returned to his former position with the Commonwealth Edison Co., Chicago. While in France Major Jackson was in charge of the electrical design and construction throughout the S. O. S. territory, with headquarters in Tours. His work in this connection corresponded very closely with that of the Construction Division of the Army in this country, although he was confronted with many difficulties in securing the necessary material and apparatus which were not encountered in the work at home. He was formerly an illuminating engineer of the company and assisted in designing the lighting for the Edison building at 72 West Adams street, Chicago.

GEORGE ELLERY HALE, director of the Mount Wilson Observatory and foreign secretary of the National Academy of Sciences, who has been for the last ten years a Correspondent of the Academie des Sciences, Institut de France, has received the unusual honor of election as Associe Etranger, succeeding Adolph von Baeyer. The foreign associates are limited to twelve, and the high distinction has been held by only two Americans—Simon Newcomb and Alexander Agassiz. The National Research Council upon the presentation and acceptance of Dr. Hale's resignation as its chairman and the election of James R. Angell as his successor, created and bestowed in perpetuity upon Dr. Hale the title of honorary chairman in recognition of his services to the National Research Council and to science and research by indefatigable efforts that have contributed so largely to the organization of science for the assistance of the Government during the war, and the augmentation of the resources of the United States through the newly intensive cultivation of research in the reconstruction and peace periods that follow.

Obituary.

GEORGE LOCKWOOD, of Providence, R. I., one of the general managers of the National Lamp Works of General Electric Co., died suddenly in the hospital on Association Island on June 26, following an operation for appendicitis. He was born in Newark, N. J., and was a graduate of the Stephens Polytechnic Institute at Hoboken, N. J. Through his connection with Stephens Institute he became associated with John W. Howell, chief engineer of the Edison Lamp Works of General Electric Co., about 1890. For about four years he devoted himself to the manufacturing end of the lamp business, but subsequently engaged in the commercial end of the business in which he continued until the year 1898, and at that time he was employed by F. S. Terry to operate the factory of the Sunbeam Incandescent Lamp Co. at Des Plaines, Ill. In 1901 the Sunbeam Co., assisted by B. G. Tremaine, inaugurated the first activity which resulted in the formation of the National Electric Lamp Association, which subsequently was incorporated as the National Electric Lamp Co. and finally merged with the General Electric Co. Throughout the entire period of development Mr. Lockwood was active in creating and developing several branches of the National Electric Lamp Co. into sound business divisions, applying himself both to manufacturing and commercial problems. At the time of his death he was general manager of the Bryan-Marsh Division, National Lamp Works of General Electric Co., this division being one of the most important branches of the National Lamp Works.

The loss of Mr. Lockwood will be most keenly felt by the National Lamp Works, not only because of his ability to operate and manage a large and important branch of its business, but because of the great love and esteem for him held by every member of the organization. He leaves one sister, Mrs Alice Lockwood Olmstead of Des Moines, Iowa. He also leaves an uncle and aunt residing in New York City. The body will be taken to Newark, N. J., for interment. Mr. Lockwood was well known throughout the country and was connected with many of the electric and electric light organizations throughout the United States. "He was one of the strongest and best liked men in the electric light industry in the entire country," said Judge J. M. Woodward, of Cleveland, Ohio, attorney for the Electric Lamp Industry of the General Electric Co.

Electrical Review

WITH WHICH IS CONSOLIDATED WESTERN ELECTRICIAN AND ELECTROCRAFT.

VOL. 75—NO. 2. CHICAGO, SATURDAY, JULY 12, 1919. PAGE 47.

Central-Station Rates in Theory and Practice

First Article of the Series—Various Kinds of Costs—General Principles by Which Service Costs Can Be Determined—Application to the Cost of Electric Service

By H. E. EISENMENGER

This is the first article of a series to appear weekly throughout this volume. A general outline of the entire series was published in the last issue. Rates for electric central-station service are generally conceded to be more scientifically and equitably developed than for any other class of public utility service. The principles on which they are based are applicable to many other kinds of service and yet they are not well understood by many public authorities, by the public in general, and even by many electrical utility managers. Mr. Eisenmenger's articles will therefore be found of great value, especially at the present time when rates are in so many cases being revised.

PART I—THE COST OF ELECTRIC SERVICE.

1. The Cost of Commodities in General.

A. THE COST OF A CERTAIN QUANTITY. TOTAL COST AND UNIT COST.

SECTION 1. The term "cost" of a certain commodity[1] is by no means a well defined one and we must distinguish a variety of interpretations.

In the first place, the term "cost" always refers to some given quantity of the commodity and it is usually—though not always—understood from the context what quantity we mean. It may be the total quantity produced (sold, consumed, etc.) in a certain enterprise, for instance per year, or the quantity purchased or consumed by a certain consumer, or the quantity of a certain shipment, etc.

Primarily, as a rule, we have given the cost of the total quantity produced, mostly per year, and desire to know the cost of the quantities purchased by the various consumers, or of other quantities of the commodity. For this purpose it is necessary to reduce the cost to some unit quantity.[2]

The term "cost" means therefore the cost of a given quantity, which may or may not be the unit quantity. Thus the cost of coal may be said to be $1000, which may mean per year, or per shipment, or per voyage of a steamer, etc., or the same cost may be said to be $4, which would mean per ton.

To avoid such ambiguities, the cost of a certain quantity, other than unity (especially the quantity produced, sold, consumed, etc., by a certain enterprise during a year or other unit of time) will hereafter in these articles be called the "total cost" where necessary to distinguish it clearly from the "unit cost," that is, the cost per unit quantity.

Where we have a number of constituent quantities, for instance several classes of service, the cost of producing several of these quantities simultaneously will be called their "combined cost."[3] We can thus distinguish a total combined cost and a unit combined cost. If the constituent quantities comprise all parts of the quantity produced by the manufacturing enterprise, for instance in a year, the combined total cost will be called the "aggregate cost" in these articles. This is the entire (annual, monthly, etc.) cost of the enterprise.

The same distinctions as to the quantity of the commodity must be made in case of income, profit and price, so that we distinguish a total income, profit and price and a unit income, profit and price.[4]

B. COST INCLUDING OR EXCLUDING CAPITAL EXPENSES.

2. We can further distinguish different kinds of cost for the same commodity, or different meanings for the term "cost" as explained in the following:

The total annual cost necessary to maintain and run any enterprise, especially a manufacturing establishment, such as a central station, consists of two parts:

(a) The direct running expenses per annum which generally stop as soon as the enterprise shuts down, such as salaries, wages, fuel, raw materials, etc.

(b) Expenses which are the result of a certain capital being invested in the property of the enterprise.

[1] The term "commodity" is meant throughout these articles to designate anything that is being sold, whether physical goods, or the right to use them, or work, labor, service, etc.

[2] The unit to be chosen depends on the nature of the commodity. It may be, for instance, a unit of weight, length, area, cubic capacity, numbers (pieces, pairs, dozens), time, power, energy, weight-distance (ton-miles in transportation service), etc.

[3] The "combined cost" is not equal to the sum of the costs of the constituent quantities (see later).

[4] If the commodity consists in a service, the price per unit is frequently called the "rate"; electric service, for instance, may be charged "at the rate of" 10 cents per kilowatt-hour, just as we say, a train is running "at the rate of" 50 miles per hour.

This capital calls not only for interest but also for annual payments into funds for depreciation, etc.[5] These expenses remain the same whether the plant is working or not. They are not reduced if the plant reduces its output, but they are increased if the plant increases its output beyond its present capacity.

We can now call "cost" the aggregate of all of the above expenses under (a) and (b), assuming a fixed percentage of net return on the capital invested. This method is the obvious one where the capital has been raised entirely by bonds and therefore bears a fixed interest, as in the case of municipal plants. With this meaning applied to the term "cost," it is only necessary to cover the "cost" by the revenue, and no profit[6] is required to yield the expected return on the capital invested. If the gross revenue exceeds the total cost, the balance representing the profit must be applied to purposes not in direct connection with the enterprise, unless we can reinvest it for enlargements, etc.

Or we may understand the term "cost" in such a manner that it includes the running expenses (a) and only such of the capital expenses (b) as are actually a fixed percentage of the capital invested and independent of the earnings, that is, interest on bonds and on preferred stock, also depreciation charges, etc., but not the interest on the common stock ("dividend"). In that case it is necessary that the enterprise should yield more than the "cost." The variable excess of the income over cost, that is, the profit, is applied to pay the interest on the stock. That interest, the dividend, is therefore a variable percentage.

Or we may finally exclude *all* the capital expenses (b) from the amount covered by the meaning of the term "cost," so that we will have to pay out of the profit, first the fixed capital charges, such as bond interest and depreciation charges, and then apply the balance for the dividend.

Where the term "cost" is applied in these articles without further specification it will always be understood in this last sense.

In all these cases we can again distinguish a total cost of the establishment, for instance per year, and a unit cost as explained under Section 1.

C. Segregate Cost, Increment Cost, and Average Cost.

3. Another lack of definition in the term "cost" is that it may mean what will be called in these articles the "segregate cost," or it may mean the "increment cost" or the "average cost." The segregate cost of a certain portion of the total quantity produced by the enterprise is the amount it would cost to produce that fractional quantity only. The increment cost is the amount by which the aggregate cost of the enterprise is increased in consequence of the fact that the respective quantity is added to the quantity to be produced.[7] Both the segregate cost and the increment cost can be reduced to the unit produced.

[5] Interest, depreciation, and other capital expenses will be treated more fully in Sections 18 to 23.

[6] Profit is the excess of income over cost and the meaning of this term varies therefore as we apply the different meanings of the term "cost," as explained in this section.

[7] It is a general, and probably universal, truth that a larger establishment can—ceteris paribus—produce more cheaply per unit than a smaller one and an establishment of given size can produce more economically if it is producing at a rate corresponding to its full capacity than otherwise. If we have, for instance, a railway where the traffic is so small that not more than one or two trains are necessary in each direction per day, we have certain salaries for station masters, etc., to pay, just the same as if we had many more trains; a certain capital must be invested in the roadbed and buildings, independent of the number of trains running daily; the wooden ties will rot in the same time whether many or few, heavy or light trains are running over them, etc.

Supposing, for the sake of an example, that it costs

$ 600 to produce 500 units,
1000 to produce 1000 units,
1300 to produce 1500 units,

then the increment cost of 500 units over the cost of the first 500 units is $400, and the increment cost of 500 units over the cost of the first 1000 units is $300. The segregate cost of 500 units, that is, the cost of producing the said quantity by itself without simultaneously producing other units, is $600.

Both the increment and the segregate cost can be reduced to the unit. The increment cost per unit in the above example would therefore be $0.80 or $0.60, respectively,[8] whereas the segregate cost per unit would be $1.20.

We can finally also reduce the aggregate cost (see Section 1) to the unit, that is, we find the "average cost per unit." This would be in the above example in case of an aggregate production

of 500 units	$ 600/ 500 =	$1.20
of 1000 units	1000/1000 =	1.00
of 1500 units	1300/1500 =	0.867

D. By-Products.

4. Conditions frequently are not as simple as assumed so far. The first complication comes in where more than one commodity is produced by the respective enterprise. The same processes, activities, capitals invested, etc., which are necessary to produce one commodity, frequently automatically produce at the same time another one or several others. In the coal-gas business, for instance, the result of the process is not only gas, but also coke, tar, ammonia, naphthaline, etc. If one of the commodities is of paramount importance we can speak of a *main product* and of one or more *by-products,* in the sense of subordinating the latter to the main product. Or, if all the products are more or less of the same importance among one another, we can call them all by-products, meaning by-products to each other, in the sense of mutual co-ordination.

Now, the question arises: What portion of the total cost, or of any part of the total cost, is to be charged to every one of the by-products?

What portion of the annual cost of coal, for instance, is to be charged to the cost of the gas and what portion to the cost of the coke?

We cannot distribute the cost according to the number of the units produced of each commodity, because gas and coal are not measurable in the same units, and even if they were, it would not be possible to logically justify such a distribution of the cost. We might distribute the total cost according to the selling value of the totals produced of gas and coke and then, if the unit cost is required, further distribute each one of these subdivisions to the uint of gas or coal respectively. Or we may prefer some other way. Whichever method we choose, there will always be an arbitrary element about it.

It may be anticipated here that this does not apply to the *prices,* which are determined according to the value-of-service principle. This will be discussed in a later section on prices.

E. Products to Be Measured in More Than One Unit.

1. General Explanation.

5. Another complication in determining the cost per unit is encountered where the total cost consists of

[8] Frequently the conditions are such that we can assume the increment cost per unit to be constant for a wide range of the quantities of previously produced goods.

several portions or items in such a manner that the amount of each portion is determined by some other factor or element and each of these factors is measured in another unit. For instance, one portion or item may depend on the weight of the commodity produced (expressed in pounds or tons, etc.) and another one on the length of the same product (for instance in feet). Instead of theoretical explanations an example will make clearer what this means.

6. This example is the letter carrying service as furnished by the Post Office Department. The annual cost of the letter mailing service (excluding the charges on the capital invested) is composed of the two following main portions or items:

(a) The annual cost of transporting the letters, whether by rail, or street-vehicle, or on the shoulders of the postman.

(b) The annual cost of assorting and distributing the letters in the post offices.

The first item, like the cost of any other transportation service, can be assumed to be proportional to the number of ton-miles required per year, and in reducing the cost to the unit we have to use the ton-mile (or ounce-mile or some such unit). This item will therefore be constant *per ton-mile* (or ounce-mile). The second item is plainly the larger, the larger the *number* of letters is that is being handled per year and has practically nothing to do with the weight of the letters or the distance over which they are being carried, etc. The proper unit is the letter or a certain standard number (say, 100, 1000) of letters and this item will be *constant per letter.*

The total cost for any volume of service rendered during any period of time is therefore the sum of two items, one of which is the product of a constant figure × the number of ounce-miles required, whereas the other is the product of another constant figure × the number of letters carried. This applies to any volume of service, to individual letters as well as to a given mail bag filled with letters, etc. The result of the computation will be correct, no matter whether we have big, fat manuscripts or thin, little notes and whether they travel from New York to San Francisco or into the neighboring town only.

2. The Use of a Smaller Number of Elements Simplifies the Computation, but Reduces the Accuracy.

7. The question of the average unit cost of letter service will therefore be answered as: So much per ounce-mile plus so much per letter. We can, however, also refer the total cost of letter service to one of the two above elements only and ask: How much is the average cost per letter? Or: How much is it per ounce-mile? This is easily figured out, but if we try to apply it to a given letter or portion of service (mail bag) it will furnish correct results only if in that letter (bag of letters, etc.) the ratio of the ounce-miles to number of letters happens to be the same as in the entire service over the whole year. If we apply, for instance, the average figure per letter to a very thin letter traveling over a short distance, the computation will furnish too great a value because we figure the cost as if the letter would require a greater number of ounce-miles than it actually does. Conversely, if we apply to such a letter the average figure per ounce-mile the result will be too small, etc.

3. The Use of a Greater Number of Elements Enhances the Accuracy, but Complicates the Computation.

8. We have now obviously a certain inaccuracy, not only if we reduce the cost to a single one of the items, but also in the case where we use both of the above items (cost of transportation and cost of handling) since these items are not really the only ones (as has been assumed so far) which have a bearing on the cost of service, even though they are the most important ones. We have to correct, therefore, the statement made above in Section 6 and say: "The first item (a) is *practically* constant," or "nearly constant," or "does not vary much" per ounce-mile, and the same correction applies to item (b) per letter or per 1000 letters, etc.

We can, therefore, increase the accuracy by increasing the number of "elements" or "items" (cost of transportation and cost of handling in the above example) which we choose to consider for the computation of the cost. We might use, for instance, three items: (a) the cost of transportation between railway stations or ports (per ounce-mile); (b) the cost of transportation within the distance of a given post office, that is, from the letter box to the post office, between the post office and the railway station and from the post office to the addressee (per ounce-mile); and (c) the cost of handling the letter.

Whether we select from the indefinitely large number of these elements one, two, three, or four, etc., and where we draw the line between the most important ones and those of lesser importance, is to a certain degree a matter or abitrary judgment, and the decision will have to be guided by considerations of practicability. *The larger the number of elements we choose, the greater will be the accuracy and the smaller will be the deviations in the individual case.* At the same time the computation will become more complicated. We have to strike in this case (as in so many others) a happy medium, and steer a safe course between the Scylla of complication and the Charybdis of inaccuracy.

4. Increasing the Accuracy With a Given Number of Elements by Subdividing the Customers Into Classes.

9. We can, however, with a given number of elements chosen, increase the accuracy with less complication in the following way. We subdivide all the customers or all the cases in which the respective business is transacted, into a number of classes or groups, selected in such a manner that the unit cost of each one of the considered items—that is, of ounce-mile and letter in our case—is most nearly constant for all customers or parts of business within each group, but varies from one group to another. For instance, we might classify the letters according to the distance over which they are carried into local, interurban or domestic, and international letters. Then the answer to the questions, "How large is the cost per letter?" or "How large is the cost of transportation per letter?" will be more accurate, that is the individual deviations from the average will be much smaller. The average cost per local letter will be one figure, per interurban another, and per international a third one. Or we might classify the letters according to their weight: or according to the location of the addressee into the three classes of rural, suburban and business district letters. The transportation charges for the rural letters will be higher than in the other classes because the letter-carrier has to walk a longer distance from the post office and between the houses, etc. We may, of course, also combine two or more of these classification systems and differentiate heavy and light rural letters, heavy and light suburban letters, etc.

Employing this principle, we can increase the accuracy with less inconvenience than when we employ an additional item.

II. The Cost of Electric Service in Particular.

A. The Three Elements of Cost.

10. The problem of properly expressing the unit cost of electric service can be solved in an entirely analogous manner to that previously described.

Just as we can say, the cost of letter service is so much per ounce of letter, we can also say electric service costs the central station, for instance, 3 cents per kilowatt-hour. That would mean that it costs 3 cents to furnish the current for burning a 100-watt lamp for ten hours or for obtaining one horsepower during one hour at 74.6% motor efficiency, etc. This is certainly a very clear and simple statement of the unit costs, but unfortunately it does not tell us much, unless we know the exact conditions under which the current is being furnished. It tells us no more than if we hear that it costs the Post Office Department one cent, or some such figure, to transport, handle and deliver a letter or one ounce of letter, without any statement about the distance over which the letter is to be carried or about the weight of the individual letter, etc. Yet we frequently read statements of the cost of electric power in terms of kw-hr. They are worth anything only if the special conditions of the case are known. They give over-all averages only. It may cost the same central station ½ cent per kw-hr. to serve one customer and 10 cents or more to serve another.

In accordance with what has been shown in the example of the letter service, we would have to have a large number of elements which have a bearing on the cost of the commodity selected, in such a way that a certain portion of the total annual cost of the central station is proportional to the number of units per annum of one of the elements, another portion to the number of units of another element, and so on. In order to avoid too great a complication and to get practicable results, we generally limit the number of these elements to three, and more or less neglect the rest as they are of lesser importance. More accurately speaking, we average the small remaining part of the total cost which is not proportional to any of the three items of cost, *somehow* into the three items.

(The reader should keep in mind that we are at present dealing with the cost to the central station and not yet with the systems of charging the consumer.)

The three items for the computation of the cost are:

(1) An item proportional to the number of kilowatt-hours generated or sold.[1] This item is therefore constant per kilowatt-hour. It is called the kilowatt-hour cost or *energy cost.*

(2) An item proportional to the maximum number of kilowatts[2] loading the central station. This item is therefore constant per kilowatt; since the maximum power in kilowatts is called the maximum demand, this item is called the *demand cost.*[3]

(3) An item which is caused by the mere fact the consumer *is* a customer of the central station. This item is independent of the amount of service required by the customer, as the second item in the example of the letter-mailing-service cost (assorting the letters) was independent of the weight of the letter and of the distance over which it had to travel. This item of central-station cost is proportional to the number of customers and is constant per customer. It is called the *customer cost.*

These three items will be discussed more in detail in the following installment.

Insert 1—(Appendix to Section 10).

Explanation of the Terms "Horsepower," "Kilowatt," "Kilowatt-hour," Etc.[4]

If a weight is lifted up by some force it requires "mechanical work" to do this, and if it is lowered mechanical work is set free. Work is measured in foot-pounds, which means the unit of work is the foot-pound. A foot-pound is the work necessary to lift one pound one foot high. To lift 1 lb. 2 ft. high 2 ft.-lb. are necessary, and to lift ½ lb. 2 ft. high, evidently one-half of that amount is necessary, namely 1 ft.-lb. In the same way we can say, one foot-pound is the work necessary to lift 10 lb. 1/10 ft. high, or 1/100 lb. 100 ft. high, etc. It is seen from these examples that the work is given by the product, force × distance.

The rate at which work is being done is called *power*. Power is the work done *per second*. It could be measured in foot-pounds per second, but this unit is inconveniently small for the purposes of the engineer and therefore a unit has been chosen which is 550 times greater, or which, in other words, amounts to 550 ft.-lb. *per second*. It is called the *horsepower* (hp.). A horsepower is, therefore, the power of one pound falling 550 ft. *every second*, or, for instance, 100 lb. falling 5.5 ft. every second. Conversely, 1 hp. would be required to lift 100 lb. 5.5 ft. every second. A water fall, for instance, which pours 880 cu. ft. (55,000 lb.) of water *every second* over a head of 100 ft. would, if harnessed, be able to produce 10,000 hp. (provided that no power would be lost in the turbines).

The electrical engineer uses other units besides the horsepower: the *watt*, which is about 0.738 ft.-lb., and the *kilowatt*, which is 1000 times as great as the watt. A kilowatt is, therefore, the work done by 1 lb. falling 738 ft. *every second*. One kilowatt = 738/550 = 1.342 hp. and one horsepower = 550/738 = 0.746 kw. The kilowatt, the watt and the horsepower are, therefore, different units for the same thing, just as the mile, the inch and the kilometer, or the dollar, the cent, and the shilling are different units for the same thing.

One kilowatt produces 738 ft.-lb. every second, or 2×738 =1476 ft.-lb. in two seconds, 2214 ft.-lb. in three seconds, etc., and 7380 ft.-lb. in 10 seconds. We can also obtain the same work of 7380 ft.-lb. from 10 kw. and then it will take us only one second, instead of ten. We see that the work is given by the product of power × the time during which the power is being applied.

We have thus been moving in a circle. We have seen that if a certain work has to be done within a given time—

[1] Not all the kilowatt-hours generated are sold. Some of them are used for the home consumption of the central station and others are lost in the transmission to the consumers. But the kilowatt-hours generated and sold can be assumed to be proportional to each other and it does not make any difference whether we assume the energy generated or sold to be the basis of the computation of cost and, in the first case, whether we include the home consumption or not, as long as the units are consistently understood in the same manner. Where it comes to the computation of cost as a basis for the price to be charged to the costumers it is evident that the energy sold is to be taken into consideration only.

[2] The non-technical reader whose ideas about the difference between the meanings of the terms "kilowatt" and "kilowatt-hour" are not quite clear is referred to Insert I.

[3] Some of the readers who are not familiar with electrical engineering may find it useful to have the difference made clear between the first and second item in plain though quite unscientific terms as follows: Imagine a lighting installation with lamps all of the same size. Item (1) of the cost, the energy cost, is proportional to the number of kilowatt-hours, that is, in this case to the number of lamp-hours. (The term "lamp-hours" means the sum of the burning hours of the individual lamps.) Item (2), the demand cost, is proportional to the maximum number of kilowatts (or, what amounts to the same thing, to the maximum number of watts) drawn by the consumer at any time, that is, in our hypothetical case proportional to the maximum number of lamps burning simultaneously. Thus, 100 lamps burning for 20 hours would contribute five times as much to the demand cost as 20 lamps burning for 100 hours, but they would contribute the same amount to the energy cost. On the other hand, 100 lamps burning for 80 hours would cause the same demand cost as 100 lamps burning for 20 hours only, but they would cause four times the energy cost.

[4] The object of this appendix is not to give a scientific explanation of the terms "kilowatt" and "kilowatt-hour," which are so frequently encountered in central-station and rate practice and which are not always fully understood, but to give the commercial man a clear working insight of what is meant by these terms. It deals, therefore, rather with examples than with definitions, and scientific exactness of expression is sacrificed for brevity and clearness.

for instance, a second—this means a certain "power." And now we see that if a certain power is applied for a certain length of time the result must be again mechanical work.

The work done by one horsepower every second is called a horsepower-second and that done by a kilowatt every second is called a kilowatt-second. According to the preceding paragraph a horsepower-second and a kilowatt-second are units of mechanical work just as the foot-pound. Indeed the horsepower-second equals 550 ft.-lb., as is easy to understand, and the kilowatt-second equals 738 ft.-lb.

Similarly, the work done by one kilowatt during one whole hour is called a *kilowatt-hour.* A kilowatt-hour is evidently 3600 times as big as a kilowatt-second, because an hour contains 3600 seconds. A kilowatt-hour has, therefore, $3600 \times 738 = 2{,}656{,}800$ ft.-lb. In exactly the same manner we can talk about a horsepower-hour, which is $3600 \times 550 = 1{,}980{,}000$ ft.-lb.

It is also clear that we can obtain one kilowatt-hour either by using one kilowatt for one hour, or two kilowatts for one-half hour, or 60 kw. for one minute, or 1/10 kw. for 10 hours, etc.

Electrical work is generally not called "work" but "energy."

It is important for the student of electric rates to get the difference between kilowatt and kilowatt-hour quite clearly fixed in his mind. The following may prove helpful. A salary of $100 per month is not the same as a capital of $100. The relation between the two is the same as between the kilowatt and the kilowatt-hour. A salary is *the rate* at which a man gets his money. It is money *per month,* measured in dollars *per month,* just as the kilowatt is *the rate* at which work is being done (energy being supplied), measured in foot-pounds *per second.* If we multiply salary by months we get a certain amount of money, which may be capital, and if we multiply kilowatts by hours we get work or energy, kilowatt-hours. Thus $500 per month during two months results in the same amount of money as $100 per month during ten months, namely $1000. Just so 5 kw. for two hours result in the same work as 1 kw. applied during 10 hours, namely 10 kw-hr. or 26,568,000 ft.-lb.

Power (kw.) corresponds to..........Salary (earning power), $ per month.

Work or energy (kw-hr.) corresponds to........Capital (accumulated salary), $.

Just as the power is the rate at which work is being done or consumed, so velocity or speed might be defined as the rate at which a distance is increased or decreased. The speed of a ship, for instance, is the rate at which the ship is moving away from a certain point (or towards it) and it is measured in (nautical) miles per hour, just as the power is measured in foot-pounds per second. The velocity of one mile per hour is called "one knot." Now the term "one knot" does *not* mean "one mile." The expression sometimes heard, "a speed of twenty knots per hour," is nonsensical. The knot is a certain speed, a rate of progress in miles per hour and a mile is a certain length, a certain total progress, so to speak, irrespectively of time. Instead of "one mile" we could also say "one knot-hour," although the term is not customary. Just so the kilowatt or watt or horsepower is a certain power, or rate at which work is being done or consumed, corresponding to the knot, and the kilowatt-hour or watt-hour or horsepower-hour, corresponding to the "knot-hour," is a certain work *irrespective of time*,* and can be measured, for instance, in foot-pounds.

Kilowatt, watt or horsepower means the rate at which an engine or some other device is generating or consuming work. An engine is running at 1000 hp. at a certain moment, a ship is using 5000 hp. for its propulsion at a certain speed, an electric generator is putting out 2000 kw., an electric furnace is consuming 5000 kw. at a given moment. Frequently, however, the terms kw., etc., are used to denote the maximum or the normal output which a generating device (engine) is capable of supplying or a consuming device (lamp, motor) is capable of consuming, just as the term "speed of a steamship" may mean either the speed at which the ship happens to be running at the moment to which one is referring, or the term may mean the maximum or the normal speed of the ship. So the terms kilowatt, horsepower, watt, etc., may also be used to denote the size of an engine or other device. We talk of a 10,000-kw. generator and of a 250-watt incandescent lamp. We talk of a 200-hp. boiler, meaning a boiler which, if normally operated, gives just enough steam to produce 200 hp. in the engine which is run from the boiler.

To summarize: Kilowatt-hour means *work* or *energy;* kilowatt means the *rate* at which work is being done and in a secondary meaning the term kilowatt denotes the capacity of machinery, etc. We can get the same number of kilowatt-hours with a *large* number of kilowatts operating for a *short* time or with a *small* number of kilowatts operating for a *long* time.

(To be continued.)

* Although the term "hour" occurs in the denomination.

THE FUTURE OF ELECTRICITY SUPPLY IN ENGLAND.

The Incorporated Municipal Electrical Association, whose summer conventions have been conducted under the clouds of war and therefore in a very restricted manner for the last few years, resumed the normal character of its proceedings at the three-day meeting held at Ipswich and Felixtowe on the East Coast of England from June 18 to 20. The subjects before the convention were: "The Application of Whitley Committee Recommendations to the Electric Supply Industry" (Alderman W. Walker); "Electric Transmission" (discussion opened by S. L. Pearce, city electrical engineer of Manchester); "The Assessment and Rating of Electric Supply Undertakings" (Bailie W. Smith).

The president for the year is F. Ayton, city electrical engineer of Ipswich, and chairman of the English Electric Vehicle Committee. In his inaugural address at the meeting, Mr. Ayton said that in achieving victory in the war, electric supply engineers and their undertakings had played no small or unimportant part. Public electric supply had been fundamental to the production of munitions of war in huge quantities. Now they were on the eve of momentous changes in the organization of the electric supply industry. Whatever might have been the effects of the war in other directions, posterity would concede that, as concerned the electrical industry, the war did good by bringing the British nation to recognize first, the importance of electric supply, and secondly, the general inefficiency and the drawbacks of the present methods of electrical generation and distribution, and to take active steps towards improvement.

The difficult conditions of war time were followed by the easing off in output that came from the signing of the armistice, which afforded, in some ways, a rather welcome relief. That event, however, brought upon them at least one new difficulty of a serious character in the considerable falling off in the industrial demand and the consequent decline in revenue. "This," said Mr. Ayton, "is, of course, but a temporary condition which will right itself so soon as our industries can be re-established upon a normal peace footing, labor difficulties be composed, and the galling restrictions on export trade removed. Nevertheless, the reduction in revenue which has resulted, and which it was, of course, impossible to foresee when our estimates for the year were framed, has placed a number of undertakings, whose output was largely for industrial power, in a somewhat serious financial position. The incidence of the fuel and lighting order has also been responsible for a not inconsiderable reduction in revenue from private residence and other consumers coming within the purview of its restrictions."

In regard to the Government Electricity Supply Bill now before Parliament, President Ayton said that the association had advanced certain criticisms and recommendations and if the bill was altered as it desired in matters of detail, the important principle of public control being adhered to and safeguarded, there was little doubt that the carrying out of its provisions would be of immense benefit to the nation, and in particular to the electric supply industry.

Problems of Power Transmission at 220 Kilovolts

Field for 220 Kilovolts—Design Features of Line and Apparatus — Excerpts from Paper by A. E. Silver Before A. I. E. E.

THE dependence of industrial progress upon an adequate supply of electrical power, together with the vital need for a rational policy of conservation of the country's fuel resources, points to a probable early demand for transmission of large blocks of power from distant energy sources—coal fields and water powers. Two hundred and twenty kv. is suggested as a logical voltage for such high-capacity, long-distance transmission.

The Field for 220-kv. Power Transmission.

Visualization of the demands of this evolution points to the need of trunk electric transmission service of a capacity and range of greater magnitude than thus far developed or required. Increasing distances and increasing quantities of power require an increasing voltage for economic transmission. The quantities and distances involved in the broad field outlined in the preceding paragraph pass beyond the economic range of existing transmission voltages. The practical working out of this next step in the transmission art is a problem now definitely facing the engineer and manufacturer.

Two hundred and twenty kv. appears a logical choice for the next step in the transmission voltage schedule, because, from an appraisal of the general situation, a voltage of this order is considered adequate for the immediately pending needs of the industry and commensurate with expected growth in transmission service demands for a considerable period. Its suitability to a variety of conditions and the probable extent of its use would assure it a place in the schedule of transmission voltages which commercial needs are rapidly standardizing. Furthermore, such a voltage, while representing a step beyond present usage sufficient to afford a distinct economic advantage, does not reach so far into uninvestigated fields but that the problems of development and design can be approached with full confidence of early commercial solution.

The particular numerical value of 220,000 is in accord with the well established practice of standardization in multiples of 11,000. In some instances, it may be an incidental convenience that this voltage is the double of the extensively used 110 kv.

An illustration of the advantage for long transmission distances of 220 kv. over the highest present system voltage, 150 kv., is given in Figs. 1 and 2. This comparison is based upon a transmitted load of 500,000 kw. The same relative advantages will obtain for larger loads, and, above a certain minimum, for smaller loads.

The field of 220 kv. is not broad. Its economic application is primarily to large blocks of power and long transmission distances. It is in no sense a panacea for transmission problems generally. It presumably will infringe to some extent upon the present fields of the lower transmission voltages, but will by no means tend to supersede their use, in fact it will considerably enlarge the field of usefulness of such secondary transmission voltages as 66 kv. and 110 kv. It is not a universally suitable medium for extensive interconnection of power systems.

Power from steam-electric stations in the coal fields or from large hydroelectric stations would advantageously be transmitted over 220-kv. lines to terminal substations at important load centers or at the hubs of secondary transmission networks serving industrial areas. The introduction of transmitted power, in amounts limited only by the load demands, will constitute a strong stimulus to expansion of these networks. Power equalization between load centers might frequently best be accomplished through extension of these secondary transmission lines. Interconnection at 220 kv. would be expected only where the equalizing duty reaches a large magnitude, where there is no existing secondary transmission system suitable to serve as a basis for inter-connecting lines, or where interconnecting 220-kv. lines might function also as a supplementary or important reserve link in a main 220-kv. trunk transmission system.

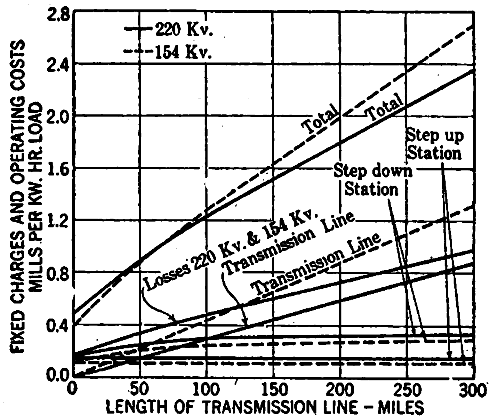


Fig. 1—Economic Comparison of 154-kv. and 220-kv. Transmission—Fixed Charges and Operating Costs—Seven Lines 154 kv. and Four Lines 220 kv.—500,000 kw. Delivered.

Costs and losses include those of lines, step-up and step-down, substations and synchronous condensers.

Costs of line per mile, 154 kv. $20,000, 220 kv $23,500—all costs based on early 1919 prices.

Size of conductor 92,900 cm. steel—716,000 cm. aluminum.

Losses based on 0.95 load factor and 0.85 power factor delivered load.

Cost of energy 5 mils per kilowatt-hour.

Fixed charges and operating expenses of transmission lines 13 per cent, substation 15 per cent.

Voltages high side of transformers, receiver end 150 kv. and 200 kv., sending end 170 kv. and 225 kv.

The initial investment in a 220-kv. system, including as essential elements the step-up and step-down stations, will be of such magnitude that there will be a strong inducement to utilize the investment as nearly continuously as practicable, thus reducing the unit transmission cost of energy supplied. The relegation of existing stations to partial operation or reserve service will be gradual, and, even when transmitted power becomes the main reliance, presumably it will usually prove more economical to maintain local stations for reserve and short peak load service than to provide necessarily expensive transmission capacity for such short periods of actual use.

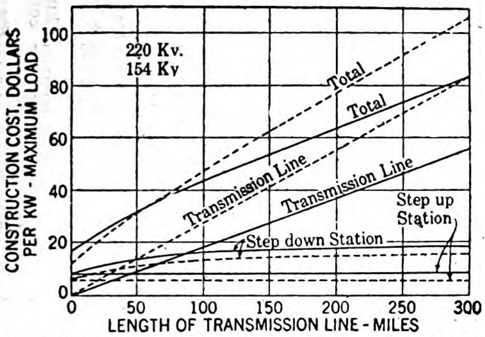

Fig. 2—Economic Comparison of 154-kv. and 220-kv. Transmission—Construction Cost—Seven Lines 154 kv. and Four Lines 220 kv.—500,000 kw. Delivered.

Costs include those of lines, step-up and step-down substations and synchronous condensers.
Costs of line per mile 154 kv. $20,000, 220 kv. $23,500—all costs based on early 1919 prices.
Size of conductor 92,900 cm. steel—716,000 cm. aluminum.
Voltages high side of transformers, receiver end 150 kv. and 200 kv., sending end 170 kv. and 225 kv.

It is assumed that even an initial 220-kv. system would be laid out on a basis of two or more main generating stations connected to load centers by a number of circuits. The load per 220-kv. circuit has been assumed to be from 100,000 kw. to 125,000 kw. A lower load per circuit than 100,000 kw. would entail a considerable sacrifice of the economy obtainable through use of 220 kv. No discussion is offered as to the maximum economic load per 220 kv. circuit since in any initial system the number of circuits would be determined from considerations rather of reliability insurance or load distribution than of maximum inherent economy. Where the studies involve a specific transmission distance, 250 miles has been assumed for purposes of illustration. The frequency of a 220-kv. trunk transmission system should be 60 cycles. Transformer connections, at all installations, should be grounded Y for the 220-kv. windings.

Corona formation and corona loss enter as a significant factor in the design of transmission lines at 220 kv.

Apparently the choice of conductor materials and types for 220 kv. service is limited, at least from the standpoint of immediate availability, to three alternatives, (1) aluminum with steel core; (2) copper with steel core; (3) all copper.

For equal conductivity, the relative physical advantages of the three types of conductors may be summarized as follows:

Aluminum-steel vs. copper-steel

1. Less corona loss, due to larger diameter
2. Skin effect presumably approximately equal
3. Greater area exposed to wind loading, hence, greater transverse tower strength and greater clearances required
4. Less tensile strength, hence more limitation upon height and spacing of towers
5. Less weight (unimportant)

All-copper vs. composite cable

1. More corona, greater than either of above
2. All material effective as a conductor
3. Skin effect more serious in larger sizes, owing to high priced material in the core
4. Less area exposed to wind loading
5. Less total tensile strength than either of above
6. Less weight than copper steel
7. Homogeneity of material, hence certain advantages in construction, more positive assurance of durability and higher scrap value

For the purpose of developing tower designs, a cable of 716,000 c.m. of aluminum and 93,000 c.m. of steel has been used in the studies.

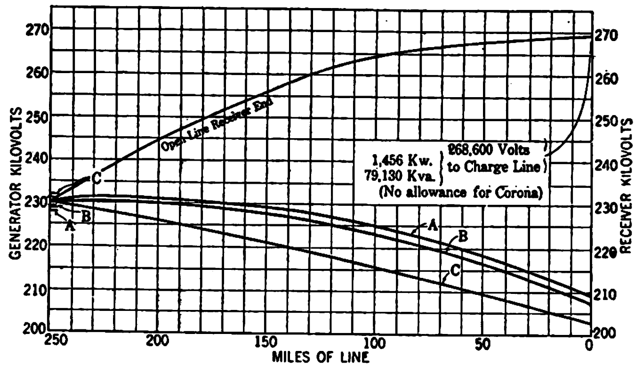

Fig. 3—220-kv. Transmission Line Characteristics—Relation Between kw., kv., p f. and Condenser kv-a.—Conductor—450,000 cm. Copper—308,200 Steel.

CALCULATION ASSUMPTIONS.

Steel core copper conductor—450,000 cm. copper and 308,200 cm. steel—20 ft. horizontal spacing.
Constant receiver volts—200,000 (low side receiver transformer—includes transformer drop).
Constant generated volts—230,000 (high side generating transformer).
Loads—delivered at 75 per cent power factor.
Transformer bank of 50,000 kw. capacity with—resistance 0.5 per cent—reactance 12.0 per cent.
Two banks of transformers in parallel at each end of line.
Losses include those of line, transformers and synchronous condenser.

RESULTS.

Curve	Rec'r kw.	Cond'r kv-a.	High voltage, 250 mile line: Receiver kv.	Receiver % p. f.	Generator kv.	Generator % p. f.	Equiv. low voltage gen. kv.	% p. f.	Losses (excl. corona loss) kw.	%
A	0	*49,000	209.0	* 0.18	230	† 5.48	227.9	† 5.56	2,704	....
B	50,000	† 7,600	207.2	*78.24	230	†96.89	228.6	†97.70	2,691	5.4

Note: *Indicates lagging quantities. †Indicates leading quantities.

The operating characteristics of a 220-kv., 250-mile line are illustrated by Fig. 3, which shows a copper-steel and an all-copper conductor the relations between power transmitted, generator, receiver and line voltages, power factor, condenser load and resistance losses.

A study of the relative economy of various sizes and types of conductors is shown in Fig. 4, with explanatory data in the accompanying table. This study shows, for a load of 100,000 kw. per circuit delivered at 0.75 power-factor and at load-factors of 60%, 75% and 90%, that the combined annual costs of such items of the transmission system as would be materially affected by the size and type of the conductor, *i. e.*, interest, taxes and amortization charges on cost of conductor, annual value of lost power on the line due to resistance and corona and of power absorbed by transformers and condensers. The curve falling lowest on the scale, at any number of years which may be assumed as the life of the line, represents the most economical of the conductors considered.

This curve is presented merely as an example of the general method followed in studying conductor economy. It does not represent the degree of refinement which would be warranted in making final determination of the economical conductor for an actual 220-kv. installation. Other items for which allowance should be made in such a study are the effect of conductor size and type upon cost of line structures and insulators, and the possible scrap value of the conductor. Amortization should preferably be calculated by the annuity or "sinking fund" method rather than by the simpler straight line method. Obviously, in any case great refinement in the technical assumptions is not called for until reasonably close values can be assigned to cost of conductor materials, for which the market will presumably be unstable for some time to come, to the equivalent costs of the power losses, and to the percentages to be employed for return on investment, taxes, etc.

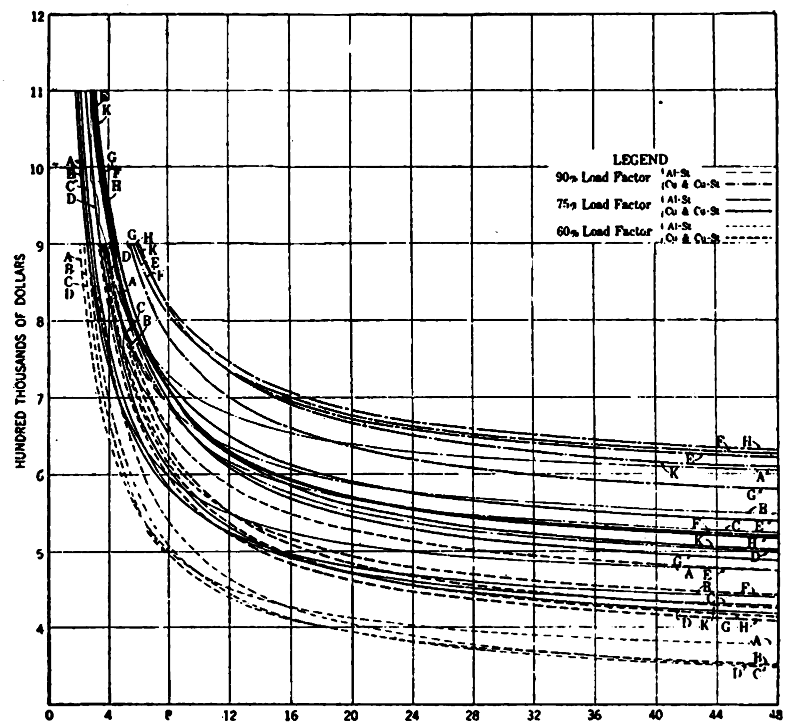

Fig. 4—Economic Comparison of 200 kv. Transmission Conductors—Annual Cost Curves—250 Miles, 100,000 kw. Single Circuit Line. (See table for explanatory data.)

Data Relating to Economic Comparison of 220-kv. Transmission Conductors.

(See Fig. 4.)

Annual Cost Curves for 9 Different Cables at 3 Load Factors.

1. Annual cost curves are plotted, dollars as ordinates, years as abscissas, and show the annual cost for any period up to 48 years. This is explained as follows:

Annual Cost Includes:
1. Depreciation expressed as first cost divided by number of years chosen.
2. Yearly interest and taxes taken as 8% of first cost.
3. Annual value of lost power taken as 5 mills per kw-hr.

First cost includes only cost of finished aluminum-steel cable at 44.9 ct. per lb. for aluminum and 12.2 ct. per lb., for steel f. o. b. factory. First cost of finished copper or copper-steel cable @ 27.7 ct. per lb. for copper and 12.2 ct. per lb. for steel f. o. b. factory. All other items of construction costs have been eliminated as not materially affecting the relative positions of the curves.

Lost power includes line I^2R, transformer I^2R, condenser loss and Corona loss.

2. Cable Data.

Curve designation.	Kind of cable.	First cost.	Alum. or copper,	Steel.	Total of cable.	Alum. or copper.	Steel.	Diam. of cable.
A	Al.-St.	$1,175,700	605,000	78,000	683,500	54	7	0.952

K	Cu.-St.	2,011,700	450,000	308,200	758,200	54	37	1.004

No type of insulator yet developed demonstrated its ability to give adequate, or even reasonably satisfactory results on high-voltage lines. It is believed, however, that practicable 220-kv. insulators can be obtained from present established types.

It should be noted that a string of 15 standard units, with the necessary connecting pieces and fittings, will be nearly 9 ft. long. Such a length of insulator obviously involves great expense in obtaining the necessary tower clearances and heights and it is also the determining feature in fixing conductor separation. This serves again to call attention to the need of more efficient and suitable insulators. An improvement in insulator design which would justify shortening the string, in addition to improving the electrical characteristics of the insulator itself, would enable material saving in tower costs. A wholly new insulator, having no greater length than necessary to insure requisite air clearances from conductor to support, say 4 or 5 ft., would enable a correspondingly greater and a very significant saving in tower costs. Such an insulator at moderate price might readily open the door to a variety of new types and arrangements of supporting structures.

Two methods are recognized as offering relief from this excessive concentration. The first is the grading of the insulator units used in the string. This would be accomplished by making up the string of units of two or more distinct types, differing in size or diameter or in some other feature which would cause them to have different condenser capacities, those with the larger capacities being placed nearest to the conductor. A second method of relieving this excessive concentration of stress consists in installing below or around the disk nearest the conductor suitably designed metallic shields or rings. The effect of such shields in improving the stress gradient may be even more marked than that of grading the insulator units.

In general either grading or shielding or a combination of the two appears to be feasible. Neither would appear to require any very elaborate investigations and tests to determine effective designs free from possibility of secondary complications of any moment. The conditions with the 15-unit string of standard units are so unsatisfactory that probably some alleviating measures should be adopted. Of the two described, probably grading could be developed to a point ready for actual use most quickly and with least experimental investigation. It is wholly possible that a considerable grading effect might be worked out through selection from present commercial types of disks.

A feature of the insulator situation which complicates the question of voltage stress distribution and which will have some effect upon methods of carrying out remedial measures is the fact that in order to obtain adequate mechanical strength, as will be discussed later, two or three strings of standard disks must be used in parallel at suspension points, and proportionately more at tension points.

The belief is widely entertained that arcing horns or rings or other discharge devices are of sufficient benefit to warrant their use. They would fulfill several functions, the first and primary function being to protect the insulator from the destructive heat of an arc. Other functions are protection of the conductor from the possible burning by a high-power arc, and reduction of the likelihood of insulator puncture. The suggestion has been offered that, with a line operating near the corona limit, high-voltage surges at high frequency, representing usually small amounts of energy, tend to dissipate themselves in corona, corona dissipation of energy being more rapid at high frequencies. In any event it is believed improbable that a line sufficiently well insulated to withstand low-frequency high-power disturbances is likely to encounter trouble from high-frequency disturbances.

The long economic life which presumably a 220-kv. line would represent causes durability of material to assume even greater importance than in present practice, so that for most localities wood construction would not be economical, even assuming that the requisite strength for the heavy loads could be secured without resorting to unduly short spans. Therefore, the conventional rigid steel tower has been adopted as the most available for construction in the immediate future, and a series of standard towers of different strengths, adapted to safe and economical use under varying conditions of span lengths and angles, are considered according to the growing practice in heavy line construction.

Features of Station and Equipment.

For 220-kv. transmission and generation certain salient features become important. For instance, design for such large capacities and high voltage centers around one cardinal principle, simplicity and intrinsic strength of equipment, rather than flexibility and external protective measures. The number of buses should be reduced even to a rudimentary form, superfluous oil switches should be eliminated, and spare or reserve units need not be provided. Of course, the complete omission of reserve equipment is predicated on adequate reserve capacity being available in local generating stations and on the high standard of construction formerly emphasized.

Considerations of simplicity in station arrangement and of economy in operation favor, in general, transformers of the largest size permitted by the conditions of each installation or by limitation of manufacture. At the present stage of the art the manufacturers advocate that transformers be not attempted beyond 50,000 kv-a. to 60,000 kv-a. for three-phase units, or beyond 35,000 kv-a. to 40,000 kv-a. for single-phase units. As to choice between three-phase and single-phase units, from the standpoint of simplicity and cheapness of installation, three-phase units would be preferable. At generating stations operating and economic considerations strongly favor making generator and transformer equipment an integral unit.

The large sizes of installations involved in a 220-kv. system, together with the necessity for careful attention to maintaining insulation strength and transformer reliability generally, will not improbably result in the abandonment of cooling the oil in each transformer and gravity circulation of oil through the windings in favor of forced oil circulation and external cooling. Short-circuit current values at 220 kv. are not extreme, and in a 220-kv. circuit-breaker the large clearances and switch openings necessarily required by the high voltage contribute directly to giving the rupturing capacity required by the current to be handled. Two types of circuit-breakers have been offered by manufacturers for 220-kv. high-duty service. One type consists of a massive circuit-breaker, each phase in one tank of heavy boiler plate, with two breaks in series for moderate duty and four breaks in series for heavy duty. The other type consists of two breaks in series per tank, one such tank being used for conditions of moderate duty and two tanks in series for heavy duty.

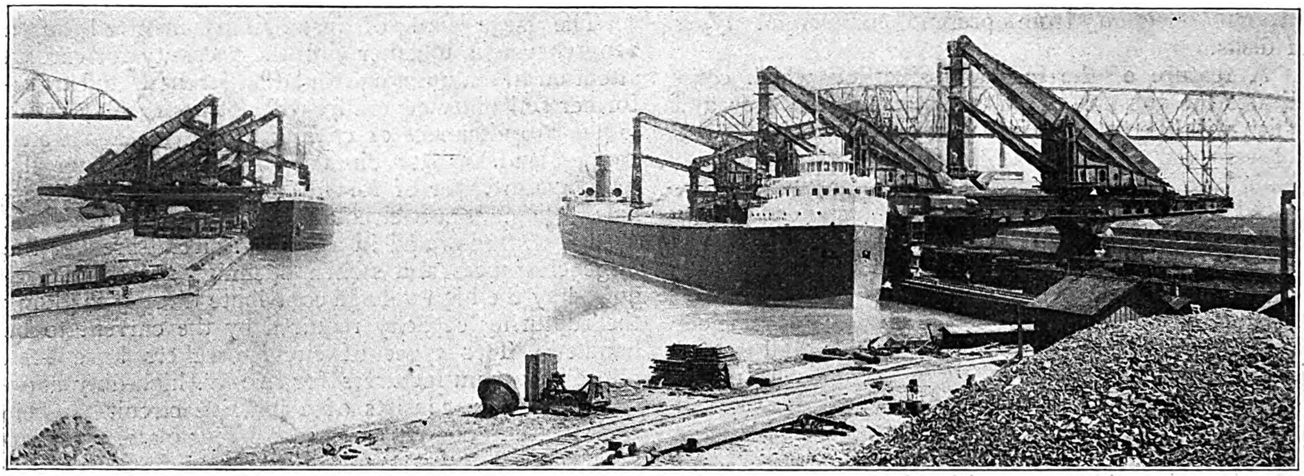
Substation layout rated at 220 kv. will be influenced largely by the particular local conditions of each installation. The usual type will probably serve to step down from 220 kv. to a secondary transmission voltage, such as 66 kv. or 110 kv. In such cases it will generally be necessary to have a primary and a secondary bus system—at 220 kv. a simple bus with sectionalizing circuit-breakers; at secondary voltage, where greater flexibility would seem desirable, probably a ring bus. Owing to the high-current values which would obtain at the secondary voltage, it appears advisable to provide sectionalizing reactors in this bus. It should be kept in mind that the large condenser capacity will aggravate short-circuit conditions.

The station and substation arrangements which have been proposed are predicated upon a relay system which may be depended upon for insuring that a faulty piece of apparatus, transmission line or low-voltage feeder will be cut out correctly, promptly and in such a manner as to avoid interruption to the other elements of the system.

Construction Cost.

The following estimates, based upon 1919 prices, capacities of 200,000 kw. and above and 220 kv, are intended to give an indication of the installation cost of construction carried out along the lines of the assumptions and recommendations in this paper:

Step-Up Substation.	
Outdoor transforming and switching structures and equipment (220-kv. apparatus and connections only), installations and indirect expense, per kw..	$8 to $9
Step-Down Substation.	
Outdoor transforming and switching structures and equipment (does not include low-tension feeder bus or feeder switching equipment), synchronous condensers of capacity for length of connected lines, building, control equipment, installation and indirect expense, per kw.	$15 to $20
Transmission Lines.	
Single circuit-steel towers-suspension insulators:	
Towers, per mile ... $8000	
Insulators and hardware, per mile ... 2800	
Conductors and ground wire, per mile ... 5000	
Special structures, per mile ... 1000	
Right-of-way, per mile ... 3000	
Indirect expense, per mile ... 3700	
Total, per mile ... ——	$23,500
Total Cost 220-Kv. Transmission.	
100 miles, per kw	$40 to $45
200 miles, per kw	60 to 65
300 miles, per kw	80 to 85



Eight Electrically Operated Ore Unloaders at Ashtabula, Ohio—These Docks Have an Unloading Capacity of 76,000 Tons of Ore Per 24 Hours, Equal to Cargoes of Six of the Largest Ore-Carrying Vessels.

Unloading Ore Quickly and Cheaply

How Iron Ore Is Unloaded from Lake Steamers by Means of Electrically Operated Automatic Ore Unloaders—Description of Modern Unloading Machine

MOST of the iron ore used as the basis of our immense iron and steel industry is obtained from the rich ore deposits near the southern and southwestern shores of Lake Superior. Iron ore is very heavy and the distance from these mines to the blast-furnace plants ranges from several hundred to over a thousand miles, consequently transportation by rail would be very expensive. Therefore, practically all of the ore is shipped by water, the Great Lakes affording a very convenient waterway for this purpose. Large, special ore steamers are used for this service. Since navigation is limited to about seven months per year on account of ice in the northern lakes, this means shipping all the ore intensively during the open season and every facility is utilized to load the vessels quickly, sail them as quickly as possible without stop to the unloading point, unload them quickly and return them for another trip.

Through the development of efficient and powerful loading and unloading machines, the cost of handling the ore and the time that the vessels are tied up at the Lake Superior loading docks and the various unloading ports have been very greatly cut down. The loading and unloading machines are electrically operated for the most part and therefore are of much interest to electrical men. Probably the highest development achieved in this line of machinery is in the unloader illustrated and described herewith. It is the product of the Wellman-Seaver-Morgan Co., Cleveland, Ohio. Over 50 of these machines are in use on the Great Lakes unloading ore steamers.

The automatic unloader shown in the accompanying illustrations is unique in design and has proved through many years of service to be one of the most successful devices for unloading ore cargoes from lake steamers that has ever been devised. Although of immense proportions, the design has been simplified and the control perfected to such a point that the machine is a marvel in delicacy of control and operation.

Description of the Unloader.

The unloader consists of a main framework mounted on wheels which travel along the runway rails which are located approximately as shown in the views herewith. The main framework extends back to the rear runway over a temporary storage pile where the ore can be discharged, if desired. Between the front and rear runways, space is provided for railroad tracks where ore-carrying cars are placed under the machines and loaded with ore for transportation to the furnace plants. The girders of the main framework form a support for runway rails on which a trolley travels. This trolley supports a balanced walking beam, from the outer end of which a stiff bucket leg depends. At the lower end of this leg is the bucket, which is operated by machinery located on the walking beam. All horizontal movements of the bucket are accomplished by means of moving the trolley backward and forward on the girders. The vertical movements of the bucket are accomplished by the operation of the walking beam. The forward portion of the beam being out of balance, the bucket descends by gravity as soon as the brakes of the hoisting mechanism are released.

The hoisting mechanism controlling this operation is located in the enclosed house at the rear end of the walking beam. Ropes from the winding drums of this mechanism pass around sheaves located in the rear end of the trolley and are anchored to the rear end of the walking beam.

In addition to the main parts of the machine which have been described, there is also a receiving hopper located at the forward end of the main framework and between the main girders; this is provided for the purpose of receiving the ore discharged from the bucket. The capacity of this hopper is about three full bucket loads and its purpose is to act as a balancing point for the ore between the bucket and the cars or storage as the case may be. The bottom of the hopper is provided with outlet gates and the contents are discharged as required into a larry which runs on an auxiliary track suspended from the under side of the main girders.

The larry, after receiving its load from the main hopper, moves to a point so that its contents can be discharged either into the cars standing on the railroad tracks beneath the main span of the girder or into a temporary storage pile under the cantilever at the rear of the machine. The ore so placed in this temporary stock pile cannot be reclaimed by means of these machines, as their function is solely one of unloading the cargo from the ships.

Machines of this type have been made in two sizes, the smaller size having a capacity of 10 tons and the larger size (such as is shown in the illustrations) having a capacity of 17 tons in the bucket shells. The machines shown here are electrically operated throughout and their speeds are regulated so as to operate through a complete cycle in about 50 seconds.

Some idea of the capacities of unloading by this method may be derived from a record which was made in Ashtabula, Ohio, by eight machines of this type having a capacity of 15 tons each, unloading seven boats having a total capacity of 70,000 tons in 22 hours actual time.

At other points, four machines working in boats having capacities up to 13,000 tons have unloaded these cargoes in about 3 hours and 25 minutes.

Method of Operating.

The operation of the machine is as follows:

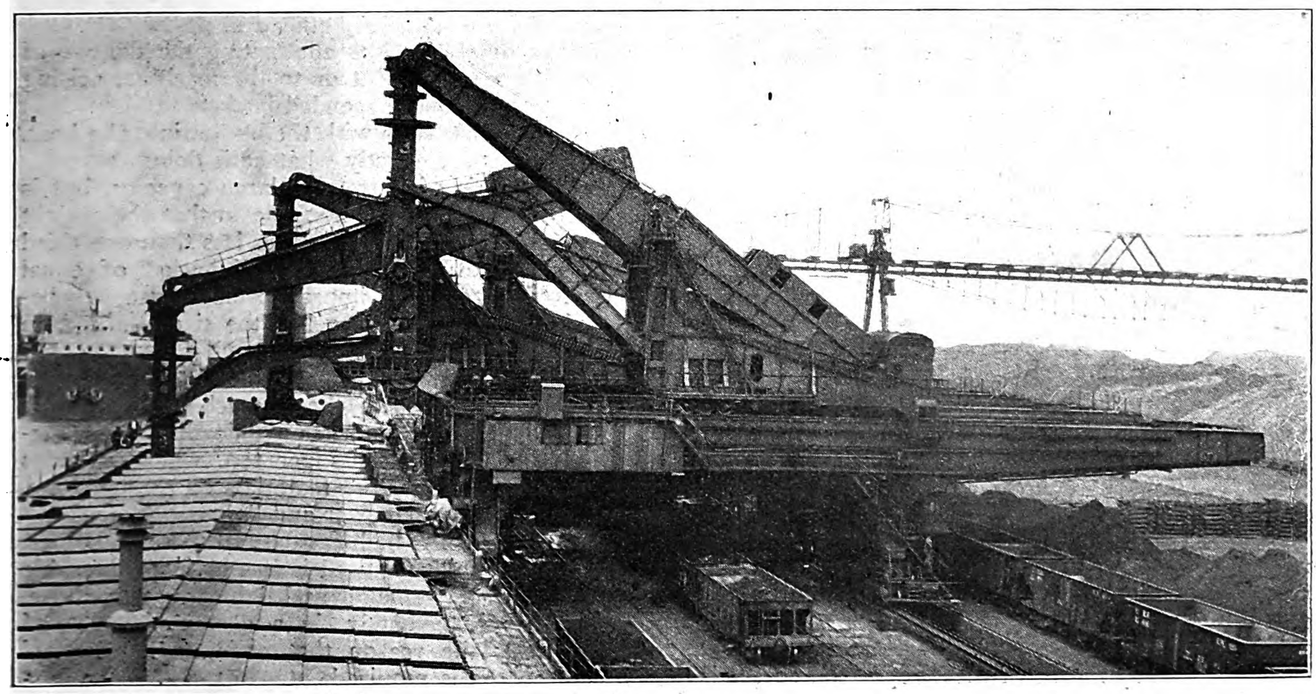
After the boat has been placed alongside of the dock, the machine is moved opposite one of the hatches and the bucket is lowered through the hatch into the ore. After filling the bucket, the walking beam hoist mechanism is put in operation and the bucket hoisted out of the boat. At the same time, the trolley is traveled back so that the bucket is brought over the main hopper between the girders and the main framework and its contents are discharged into this hopper. The bucket is then immediately returned to the boat for another load. The ore in the main hopper is discharged into the larry which has been brought to a point directly underneath the discharge gates of the hopper. The larry hopper is filled and the larry is moved over the desired discharge point and the gates of the larry hopper are opened discharging the ore as required. The larry hopper is provided with scales so that the contents are accurately weighed and recorded. In this way a car can be loaded to its allowable capacity and an accurate record kept of the amount of ore so discharged into the car, thus eliminating the necessity for the use of track scales and reweighing.

If railroad cars are not available for immediate shipment, the larry is traveled to a position on the rear of cantilever and its contents discharged into a temporary storage pile, from which it is usually reclaimed for shipment or storage by means of a bridge, located on the runway at the rear of the unloader.

Only two operators are required for the entire operation of one of these machines. One of the operators, whose station is in the bucket leg directly over the bucket shells, controls all of the motions of raising and lowering the bucket, of traveling the trolley back and forth, and moving the machine along the dock from one hatch to another. The second operator is stationed in a cab on the larry and from this station he controls the movement of the larry, the operation of the larry gates, and the weighing of the ore.

The bucket shells are each made of a single piece of plate formed to the shape as shown in one of the views. These bucket shells are usually provided with manganese-steel cutting lips which are essential to resist the abrasive action of the ore. The bucket shells themselves are carried on heavy cast-steel arms mounted on rollers traveling in guides in the fixed portion of the lower end of the bucket leg. The position of the operator who controls the operation of the bucket, etc., as previously described, is also shown in this view. It shows the bucket in operation in the hold of a modern ore carrier after most of the ore has been removed and the balance of the ore has been scraped into position so as to be handled by the bucket.

The motor for operating and closing of the bucket is located in the machinery house at the back of the

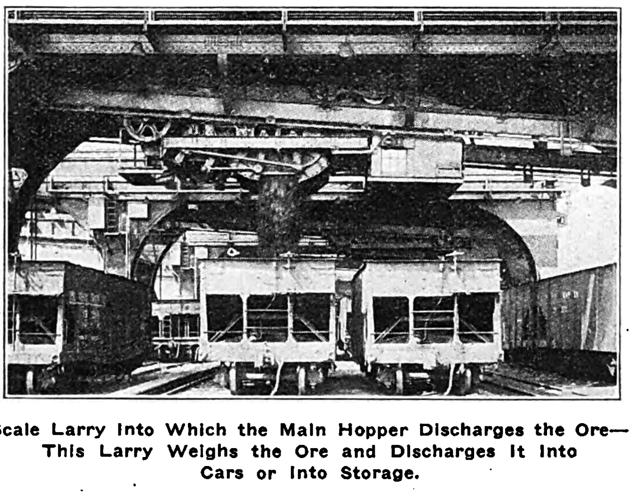


Part of the Seven Ore Unloaders at the United States Steel Corporation's Docks at Conneaut, Ohio.

walking beam. Ropes from this bucket-closing mechanism are carried through the walking beam and the bucket leg and attached to a power drum in the bucket leg directly over the operator. This power drum is geared to the closing chain drums, one of which is shown on this photograph. The bucket is closed by rotating the drums in the proper direction. The bucket is opened by reversing the motor and the bucket shells are forced open by means of an opening chain located in the center of the bucket leg between the two closing chains.

In addition to the vertical movement, which is given to the bucket leg by means of the walking beam, it also has a motion of rotation around its vertical axis. This is accomplished by means of ropes attached to a segment on the bucket leg itself, the ropes being carried back in the walking beam to a rotating mechanism which is located adjacent to the bucket-closing mechanism. The bucket leg itself is carried on a roller bearing which is attached to the top end of the leg. This motion is introduced for the purpose of turning the bucket at right angles to the hatchway in order to secure as great a reach lengthwise of the boat as possible, thus the bucket is enabled to reach out under the hatches and remove ore which is not directly beneath the hatch opening. The distance from point to point of the bucket shells when open is approximately 21 ft.

The scale larry, into which the main hopper discharges, has a capacity of between 35 and 45 tons and two larry loads are intended to constitute a full carload of ore. The arrangement of the discharge gates of the larry is clearly shown in one view. They are suspended from the sides of the larry frame and operated by connecting rods which attach to cranks, also connected to the main larry frame, these gates being operated by means of a small motor which is carried at the rear of the larry. The gates are so arranged that all or a portion of the contents of the larry may be discharged. The hopper of the larry is suspended in the larry frame on scales so that the contents of the larry may be wholly or partially discharged and be accurately recorded.



Scale Larry Into Which the Main Hopper Discharges the Ore—This Larry Weighs the Ore and Discharges It Into Cars or Into Storage.

The mechanism for moving the larry back and forth on its track is also located on the larry and consists of winding drums upon which ropes are wound, the end of the rope being attached to the rear end of the cantilever on the main framework. The larry track is inclined by means of these ropes and descends by gravity.

Electric Motors and Control.

As previously stated, these machines are usually electrically operated throughout. In some cases, however, machines of the same general type have been made to operate by steam and hydraulic cylinders, water being supplied to the operating cylinders by means of a steam accumulator which furnishes water at a pressure of 1000 lb. per sq. in. The electrically operated machines are usually designed for a 220-volt direct current. Alternating current is never used. The motors required for the equipment of one of these machines are as follows:

Beam hoist..............	1 motor, 275 hp.
Bucket closing...........	1 motor, 120 hp.
Bucket rotating..........	1 motor, 25 hp.
Trolley travel............	1 motor, 120 hp.
Hopper gates............	1 motor, 100 hp.
Longitudinal travel.......	1 motor, 100 hp.
Larry travel.............	1 motor, 150 hp.
Larry gates..............	1 motor, 40 hp.

The control equipment for these motors is of the magnetic switch type throughout, having master controllers in the operators' cabs in the bucket leg and on the larry.

Electric current is supplied to these machines by means of insulated conductor rails running the length of the main runways. The current is collected from these rails by means of pickup shoes and distributed to the various portions of the machine. A similar collecting device is also employed for supplying the main current to the trolley. Conductor rails are attached to the main framework of the machine and the current collected from these rails by means of pickup shoes attached to the trolley.

Economies and Other Advantages.

Many points of superiority claimed for the Wellman-Seaver-Morgan ore unloader, which are not found in other systems of unloading are:

The design is very heavy; there is little to get out of order, resulting in low maintenance cost per ton of material handled.

Control is accurate and positive, and manual labor is reduced to a minimum.

The bucket is positively guided in passing through the hatches of ships, thus eliminating the danger of damage either to the boat or to the machine, arising from the use of rope-suspended buckets.

The operator travels with the bucket into the boat, and can always see exactly what he is doing.

The bucket is of extremely large capacity, but is so suspended from the walking beam that the weight resting on the tank top of a boat is less than one-third of the weight of a rope-suspended bucket of equal capacity. In fact, it is impracticable to use a rope-operated bucket of anything like the size attained on these unloaders.

One particularly important point is the extremely low cost obtainable with these machines. Records extending over long periods show unloading cost ranging from 2½ to 4½ cents per ton, which includes superintendence, labor, and materials on the machine, as well as the cost for power and light.

On account of the high capacity of these machines, the number of units required is less by a considerable margin than of any smaller and lighter type machine, which results immediately in a decreased cost of operation, for the reason that a fewer number of skilled operators is required.

Again, on account of the extreme reach of the bucket, it is possible for the machine to discharge a very much higher percentage of a ship's cargo than can be accomplished by ordinary rope-operated buckets. The bucket can be rotated at right angles to the hatch and reach out for ore which would be entirely inaccessible to an ordinary bucket.

It can be conclusively shown in plants where large tonnages are to be handled that there is a distinct saving in first cost, as well as a yearly saving in the cost of operation, over any other type of machine.

Unloader Leg and Bucket at Work in Hold of a Modern Ore Vessel—Leg Can Rotate in a Circle, Allowing Bucket to Reach Out in All Directions, Taking Out as Much as 97% of Cargo Without Shoveling—Note Position of Bucket Operator Directly Above Bucket.

This unloader is not a combined machine. It is an unloader, pure and simple, and does its work well.

STREET-LIGHTING PROBLEMS OF LONDON, ENGLAND.

Review of War-Time Restrictions—Now That These Are Removed, the Whole Street Lighting Should Be Improved.

Just before the outbreak of war a plea was made by the then president of the English Illuminating Engineering Society for the treatment of the lighting of the city of London as a whole and on a uniform basis. Leon Gaster, in opening a discussion on June 24 of this year before the same society, repeated the plea, because in view of the concerted action taken by street-lighting authorities throughout London during the war the moment was ripe for asking for a continuation and extension of such co-operation in the future. The suggestion was advanced that an advisory committee should be formed on which the Illuminating Engineering Society, the London Safety-First Council and the chief authorities interested, should be represented, in order to prepare recommendations for the lighting of London on a uniform basis and in accordance with commonly acceptable principles.

Reviewing the experience of the past five years, Mr. Gaster divided the treatment of street lighting in London during the war into three distinct periods: (1) A progressive and somewhat indiscriminate diminution in light by reducing the number of lamps lighted, and restricting the pressure of electricity or gas supplied to them. (2) A period when further diminutions were made by masking lights so that only a narrow cone of light was shed on the roadway in the vicinity of lamps. (3) The period when the authorities, acting on expert advice, substituted diffused lighting, by coating a portion of the lanterns with white distemper. The last of these methods helped to eliminate the objectionable contrasts in brightness and produced a more uniform effect. Immediately after the armistice a fourth period was entered upon, the restrictions relating to screenings being withdrawn and pre-war lighting rendered permissible, subject to 50% reduction in the interests of economy.

The public was naturally inclined to a restoration of pre-war conditions, but profit should be derived from the experience of war time by securing improvement as well as restoration after all restrictions were withdrawn on the signing of peace. From this experience two points standing out prominently were these: (1) The value of diffusing appliances in lessening glare and excessive contrasts in brightness; (2) the desirability of uniformity in practice as regards the principles of street lighting throughout the entire Greater London area.

The speaker referred to the relation of lighting to traffic. He showed figures indicating the effect of diminished lighting in increasing accidents. The London "Safety First" Council had emphasized the planning of street lighting in such a way as to avoid extreme contrasts in illumination in passing from a side street to a main street, or in passing from one borough to another. It had also emphasized the following points: The provision of special lighting to facilitate the guidance of traffic at important crossings, dangerous turns, etc.; the provision of light at regular stopping places for vehicles.

Mr. Gaster expressed the opinion that one of the best peace mementoes would be the placing of the light of London on a more satisfactory and uniform basis. Among other measures the permanent lighting by concealed lamps of public monuments serving as mementoes of the war might be suggested.

In considering general problems in street lighting it was held that much remained to be done in the design of fixtures, especially for use with the gas-filled lamp, which would doubtless be largely used for future street lighting. The distribution of light needed special care, but there was general agreement that the greater part of the light should be directed on the roadway, where it was chiefly needed. Street-lighting requirements were now quite different from what they were a few years ago, in view of the great increase in the volume of traffic and the high speed of motor vehicles.

On the question of the co-ordination of public and external private lighting, the speaker said that a difficulty in street lighting was the darkness of surrounding surfaces, which prevented good diffusion of light, occasioned sharp shadows, and accentuated the glare from light sources seen against this dark background. These conditions might be improved by co-ordination between public and private lighting. If suitably shaded and diffused, such external privately installed lamps would yield valuable assistance to street lighting. Municipalities might consider co-operation with consumers in main thoroughfares, allowing a concession in charges if requirements as regards uniform procedure in equipping lamps were adopted. Similarly, the appearance by night of important streets and squares would be much improved if some light, not necessarily a large amount, were allotted to the illumination by concealed lamps of public buildings, national monuments, etc. Another important factor was the illumination of nameplates for streets, and the more general use of mildly illuminated plates indicating the nature of buildings would also be helpful.

THE INDUSTRIAL LIGHTING EXHIBIT AT N. E. L. A. CONVENTION.

Important Demonstration of Poor, Fair and Good Factory Lighting at Atlantic City Exhibition.

One of the features of the lighting exhibit under the auspices of the Lamp Committee and the Lighting Sales Bureau at the recent National Electric Light Association convention in Atlantic City, which attracted considerable attention was the novel industrial lighting demonstration. An entire room was fitted up to represent a small machine and repair shop, containing a lathe, drill press, grinder, sewing machine, and Ford truck chassis and engine. One half of the room was painted dark gray above the working-plane, and black below, while the other half was flat white above, and green below. Three separate and independent systems of lighting were installed to show poor, fair, and good practice.

The poor lighting system consisted of four 50-watt bare carbon lamps on drop cords, one 100-watt clear-bulb Mazda C lamp on a drop cord over the bench at the darker end of the room, and one 40-watt Mazda B lamp on a long extension for working under the machine chassis. The intensity provided averaged 0.8 ft-cdl., which is far below that required by any of the state lighting codes. Such an installation, shown in Fig. 1, is typical of the practice in many shops where inefficient carbon lamps and high-candlepower Mazda C lamps without reflectors are commonly used.

The fair system of lighting, Fig. 2, is intended to show the result of an attempt to increase the illumination intensity without particular knowledge of good lighting. Two 150-watt Mazda C bowl-frosted lamps in deep bowl porcelain-enameled reflectors were used to provide the general lighting, and three units with similar reflecting equipment but smaller lamps were suspended on drop cords over the benches for local lighting. The lamps used for this purpose were two 60-watt Mazda B lamps and one 100-watt Mazda C. Such a system provides something like 2 to 3 ft-cdl. intensity and would meet the requirements of a state code. However, it does not provide for the best shop efficiency.

The good lighting system represented an installation designed to give "productive intensities." General illumination at more than double the intensity provided by the fair system was supplied from eight 150-watt Mazda C lamps in RLM dome reflectors. Four of these lamps were bowl-frosted, and four were equipped with opal caps. In connection with this installation, the sewing machine was fitted with a suitably shielded 10-watt Mazda B lamp, to show a possible need for local lighting when sewing on dark goods. On the other hand, this general overhead lighting system showed conclusively that no local lighting as required in the poor system was needed for a workman repairing an automobile engine.

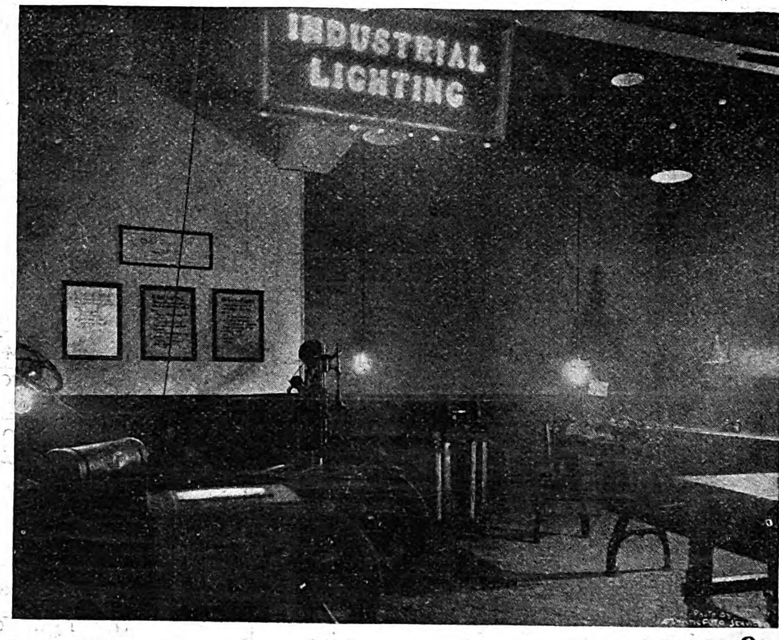


Fig. 1.—Deep Shadows and Gloom Prohibit Good Work Here.

During the exhibit a large model of a foot-candle meter was kept on the automobile chassis, to effectively show the change in intensity which occurred when the various systems were substituted one from another. The dual system of wall finish gave a convincing demonstration of the effect of white paint to increase the utilization of light and produce more cheerful surroundings.

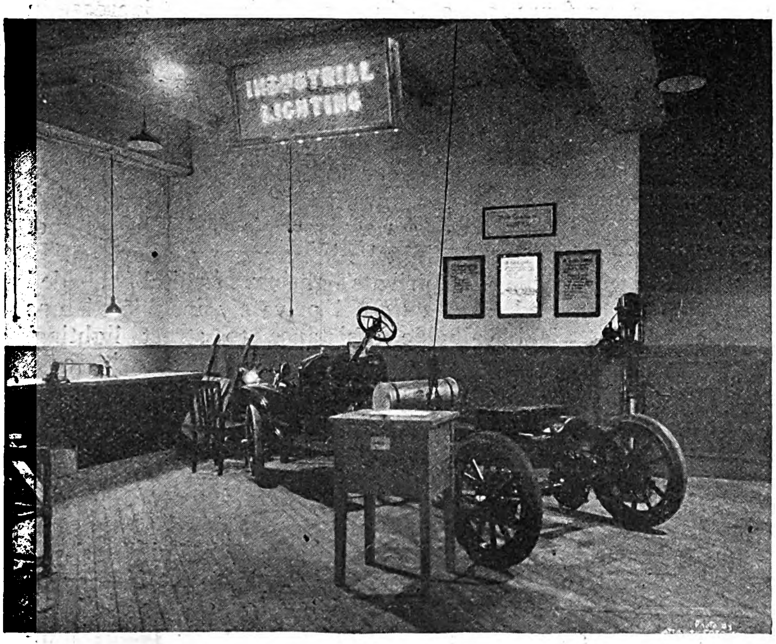

Fig. 2.—Some Improvement, But Shadows Are Still Deep.

SWEDISH DEVELOPMENTS IN THE USE OF ELECTRIC POWER.

Electrification of All Railways Being Undertaken—Demand for Appliances and Equipment Increasing.

Probably in no other country in the world, with the possible exception of the neighboring state of Norway, is there more intensive development in progress in the utilization of electrical energy than in Sweden.

There is in Sweden a remarkable tendency to apply the use of such power to every phase of the economic life of the country—to industry, to public utilities, to State and privately-owned railroads, to agriculture and to home life in remote districts as well as in the cities. The importance of the development is out of all proportion to population. Sweden's population is less than that of New York City, and is widely scattered over an area of 173,000 square miles, broken by mountains, and extending within the Arctic Circle.

Sweden possesses some coal, but it is not of the highest quality, and the supply is inadequate for domestic needs. Her immense forests are her greatest present source of national income, but the day has passed when wood fuel can be broadly and economically employed. War markets afforded great incentive to the expansion of old and new industries, yet the difficulty and cost of importing raw materials, especially coal, created a handicap which would have been insurmountable but for the driving power at hand in the Swedish lakes and streams. The value of existing and future development of this tremendous national asset has been emphasized by bitter experience.

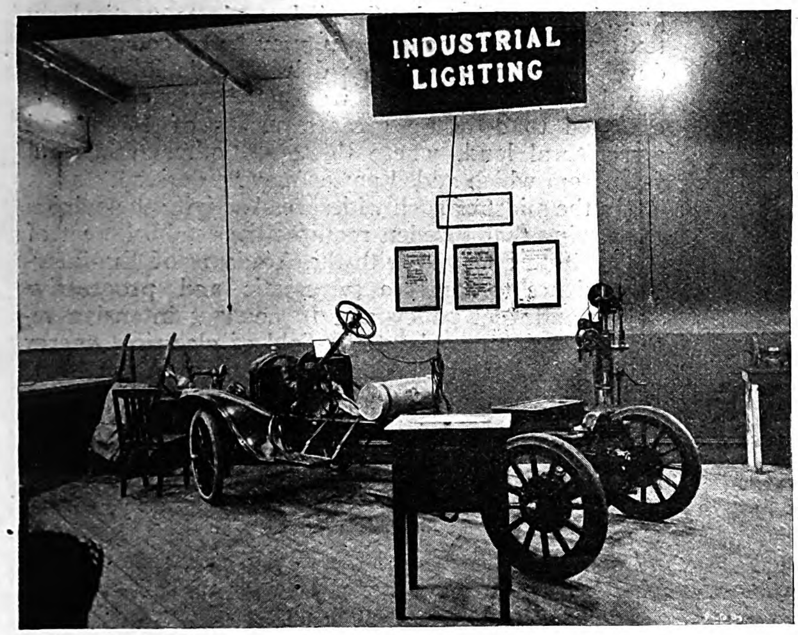

Fig. 3.—Note the Absence of Dense Shadow, the Definition of Detail, and the Cheerful Atmosphere Under a Properly Designed System.

Great strides were made during the war, and greater developments are planned. Sweden has seen a new vision of industrial and commercial greatness, but the past four years' experience has brought home to her the weakness of her position so long as she is dependent upon imported fuel. The solution lies in a full utilization of her magnificent "white coal" resources, the development of which is proceeding on a remarkable scale. There is no desire to repeat the war experience of running her railroads on wood, 40,000,000 cubic meters of which was consumed in 1917, or upon imported coal at 175 crowns ($46.90) per ton, the price in October, 1918. Power, comparatively cheap, abundant, and available with little regard to conditions abroad, will assist immensely in realizing the industrial and commercial possibilities.

The amount of water power normally available in Sweden may be conservatively set at 5,000,000 hp. Such a figure places her above any other country in Europe in this respect, with the exception of Norway. Water power has been used in her industries for centuries, and before the outbreak of war produced more than one-half of the mechanical power in the country, the total consumption exceeding 1,000,000 hp.

The demand for electrical energy has not been confined to any particular branch of industry. The call has been universal from the great iron mines of Norrland, within the Arctic Circle, to the extreme South, where power is already being transferred to Denmark by cable and still greater export is planned. The electrification of the railroads has already commenced and it is to be pushed as rapidly as possible. It is felt that trains must be made more rapid and the locomotives more powerful, to attain higher average speed rather than a greater maximum speed. In many cases of long hauls, as for instance, Stockholm to Kiruna, it is believed electric operation will cut the running time in half.

In 1915 the Government requested the Railway Department to make a thorough investigation and report on the question of electrification. The report, only recently completed, states that in view of the desirability of extending the existing system, the abnormal cost of fuel, and the greater efficiency and economy possible, the introduction of electric service is essential. It is estimated that the work will require ten years and it is proposed that separate conduits be established for lighting along the railways and for the distribution of power to agriculturists. It is felt that electrification would be profitable even were water power not available, since coal can be utilized in a steam power station with far greater efficiency than in the locomotive. Peat and inferior coal could also be used if necessary.

It has been estimated that the saving in fuel alone during the last four years, if the system had been electrified at the outbreak of war, would have equalled the entire cost of installation. Railroad coal, which cost $20 per ton in 1917, had risen to $46.90 per ton in October, 1918. The fuel item alone in the latter year amounted to nearly 70% of the entire cost of running the State lines in 1917, and largely accounted for the net deficit resulting from gross revenues never before approached in Swedish history.

Electrification has already been applied with a high degree of success. The first attempt on a large scale, aside from the electric street railways of such cities as Malmo, Göteborg, and Stockholm, was on the Kiruna-Riksgränsen line in Norrland, well within the Arctic Circle. This line is 93 miles long and carries annually a heavy tonnage of iron ore. Single-phase current at 80,000 volts is sent from the Government power stations at Porjus to four transformer stations along the line, of which the first is 87 miles and the last 160 miles distant. The voltage is stepped down to 15,000, at which voltage power is supplied to the contact device.

The freight locomotives in this case weigh about 100 tons and the passenger locomotives about 70 tons: A normal freight train includes 2 electric locomotives and 41 cars of 46 tons each, a total weight of 2000 to 2100 tons. Normal speed for freight is 18½ m.p.h. and the maximum 31 m.p.h. Maximum speed for passenger trains is 62½ m.p.h. In the first year of operation the road transported 1,104,000 tons of ore, barely one-third of its normal capacity. In spite of this low traffic, a distinct saving over steam operation was scored.

For the electrification of railways seven main sources of power are available: Lagan; the Indal, Ume and Dal rivers, the power plants on the Lule river, the stream of Motala and the Göta river. Many of the existing installations are already fully loaded. Trollhättan, one of the two great State power undertakings, has been several times enlarged and now yields 150,000 hp. with a normal supply of water. It is said, however, that it will be fully loaded in 1921, though a complete system of water-economy and the regulation of Lake Vänern may increase the capacity to 300,000 hp. The Vargön Fall and Lilla Edet, also on the Göta river, are expected to yield 40,000 hp. and 65,000 hp. respectively. The first installment at Lilla Edet, to yield 26,500 hp., is already in process, the works being so planned that extensions can be made when needed.

The Motala works are being equipped for an initial yield of 10,000 hp. The Lule river has been estimated to be capable of producing 600,000 hp. The great Government plant at Porjus, which already supplies current for the Kiruna-Riksgränsen line in Noorland, will require its maximum capacity to meet projected railway and large-scale industrial demands in that territory. Works at Harspränget, also on the Lule, are planned on a basis of 150,000 hp., and the same river affords other falls worth harnessing.

It is further proposed to link up Trollhättan and the power system of East Sweden, called the Alvkarleby system, to permit a more complete utilization of all power generated in these widely separated regions. The State owns the important falls at Vargön and at Tyttbo, on the Dal, and it is proposed to harness them soon, as well as to regulate the level of Lake Vänern and undeveloped sites on the Dal. Other falls, such as those at Kerseforsen in the Lagan and Ljungsfallen on the Motala river, are being held in readiness to assist in the electrification of the railroads.

New power works completed during 1917 comprised about 65,000 hp., including a third instalment at Trollhättan of 26,500 hp. Works begun during 1918 called for 90,000 hp., including 25,000 hp. additional at Porjus. Stockholm has just begun to receive power from the new station near Untran, which cost the city about $8,000,000. The installation will deliver about 14,000 kw. and is said to effect a saving of $4,000,000 annually in coal. The transmission line has a voltage of 100,000, greater by 30,000 volts than the previous pressure.

The Torpshammer Aktiebolaget is building a new power plant at Torpshammer (Sundsvall) to develop 30,000 hp. to supply the growing industries at Svärtik. While a new company, with headquarters at Norrkoping and a capital of $800,000, it expects to effect a more efficient distribution of the energy already available to certain districts in Oestergotland. Still another power station is projected at Agnas, near Bjursholm in the county of Vasterbotton. The company involved has a capital of $26,800, but no information is available as to the capacity of the installation. The marked tendency of Swedish industries toward consolidation is instanced by the recent formation of the Aktiebolaget Bergalagens Combine Power Control, a combination of 33 of the largest power producers of central Sweden. The purpose of this body is at present said to be rather the more complete utilization of the existing productive capacity of its members than the construction of new stations.

It is interesting to note the growing effort to provide electric power throughout Sweden for other than industrial requirements. The Railway Department's report upon the electrification of the roads recommends the distribution of power to argiculturists, while the whole question of the electrification of country districts has now been taken under detailed consideration by Royal Commissions, by county councils and by various agricultural societies. The councils in particular have been urged to take a more general interest in those districts particularly suited for the spreading of information and the formation of the necessary organizations. It is hoped that by such means, coupled with the creation of free ports and the improvement of the existing canal system by which many inland industrial centers may be stirred to greater activity and made accessible to ocean shipping, home markets for Swedish products, particularly textiles and household goods, may be extended. The development of electrically driven roads in northern Sweden, where immense iron mines are located, is expected to open up great stretches of forest and agricultural land, where there are other important falls from which added power may be derived.

In the midst of such widespread activity the opinion is growing that Sweden requires the establishment of an Institute affiliated with the Academy of Engineering Science to draft a systematic and progressive power and fuel policy and to conduct intensive research work throughout the field of electrical energy and its application. This movement apparently has the hearty support of the press and the Water Power Commission.

The latter body, granted $2,200,000 in 1918, asked an additional $268,000 for the purchase of further sites, etc., the same amount for the current year, and $690,000 for 1920, to be used in the construction of new power stations and the improvement of existing plants. Apparently the appropriations sought had reference to the new stations planned at Tyttbo and Umea and extensive improvements at Norrforsarna and Sorforsarna Stations.

To foster such development as has been outlined above the Swedish Government has recently created the State Water Power Loan Fund and the State Power Transmission Loan Fund, with yearly grants of 2,000,000 kroner and 1,000,000 kroner respectively.

The stated purpose of the first fund is to permit loans up to two-thirds of the cost of harnessing waterfalls belonging either to the State or to private individuals and for the regulation of water levels; the last is for loans to co-operative associations for the building of distribution systems and power-transmission wires. It was found, however, that the appropriations were insufficient, since applications under the Transmission Loan Fund soon reached 6,000,000 kroner. The Board of Trade and the Board of Agriculture, in a joint memorandum, have asked that the sums available be doubled during 1919 and 1920 in order to permit greater assistance in the electrification of the country districts.

The above indicates something of the magnitude of existing and projected hydroelectric development in Sweden. Progress during the war would have been even more rapid but for the difficulty of importing finished equipment and raw materials required for domestic manufacture of turbines, dynamos and other machinery. Such articles as lamps, fuses, switches, electric motors, and numerous other items had been almost exclusively imported from Germany. The electrical industry, for a long time very important in Sweden, expanded as greatly during the war as the shortage of raw materials would permit, but the sudden accession of interest in electrification and industrial expansion throughout the country has created a great demand for mechanical and electrical appliances of all kinds.

The production of the heavier types of machinery required is an important industry in Sweden, but the drop in her German imports in many allied lines has been seriously felt.

Heretofore, Sweden has paid heavy toll to Germany for her lack of direct shipping connections with outlying countries. Plans now being formulated will bring Swedish ports into direct and regular communication with this country and the new policy of her big men is predicated upon the cultivation of closer commercial and financial relations with the United States.

The rapid development of the electro-metallurgical and chemical industries in Sweden is reflected in the following table:

Year.	No. Plants.	No. Kilowatts.	Value Product (Kroner).
1904	8	9,000	4,500,000
1908	10	13,500	7,500,000
1911	14	25,000	11,000,000
1913	22	60,000	20,000,000
1915	36	78,000	31,000,000
1917	75	128,000	55,000,000

Prior to the war our part in supplying electrical equipment to Sweden was almost nil. The following figures show the importance of the trade from the German standpoint. It is only in the past two years that our share has grown appreciably and it would appear to be entirely up to the American exporter of these commodities whether the figures rise to new heights or fall back to their old level.

GERMAN EXPORTS TO SWEDEN.

	1909	1910	1911	1912	1913
Electric Cables	$1,023,000	$1,021,000	$752,000	$565,000	$500,000
Electric Appliance for Illumination, Transmission of Power, etc.	188,000	262,000	334,000	340,000	481,000
Electric Incandescent Lamps	340,000	329,000	513,000	373,000	406,000
Electric Meters, Registers, etc.	99,000	151,000	189,000	217,000	261,000

U. S. EXPORTS TO SWEDEN.

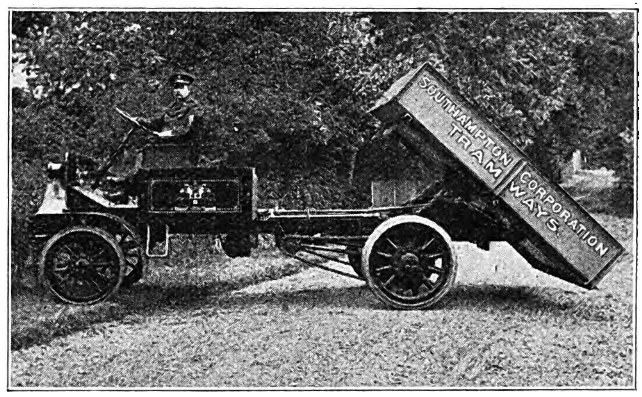
	1913.	1914.	1915.	1916.	1917.
Batteries	.....	$ 569	$ 3,809	$ 537	$ 8,540
Dynamos or Generators	48	.....	.....	1,168	17,359
Ins. Wire and Cables	.....	1,253	535	1,276	29,406
Meters, other Meas. Instruments	.....	.....	2,000	1,858	1,150
Motors	5,298	1,400	6,400	711	11,000
Transformers	.....	30,113	.....	.....	.....
All other	5,500	10,700	19,000	31,500	88,500

In spite of the handicaps of the war period, Swedish private enterprise and the purchasing power of the people have increased, and her labor situation appears more favorable than that of her neighbors. A period of temporary depression must follow the speculation and rapid expansion of the war years, but Sweden's future for the long pull never appeared brighter than at present.

STORAGE-BATTERY DUMPING WAGON FOR SOUTHAMPTON TRAMWAYS.

The accompanying illustration shows a 2-ton electric battery dumping or tip wagon that is in use on the municipal electric tramway system at Southampton, England. It is employed for permanent way and general carting work. It was introduced during the earlier years of the war and our picture which was then on the way to the ELECTRICAL REVIEW was intercepted by the British postal censor and in due course found its way back to our British correspondent. It is not apparent on the face of it what secret intelligence the said censor imagined the picture was intended to convey, but as the press postal censorship was recently withdrawn, we are now enabled to leave the reader to solve the riddle.

W. T. Robson, general manager and engineer of the tramways, tells us that the vehicle has been in daily service for three years without a break and is still running satisfactorily. Writing to our correspondent in August, 1916, Mr. Robson said that there was ample



Southampton's Battery Truck Dumping.

evidence to show that a considerable financial saving would result. In reply to an up-to-date inquiry, he says: "We have not worked out any recent costs, but I may say that the vehicle has displaced three horses, carries out all our own carting work, and in addition we are able to loan it for the benefit of other departments to a very great extent indeed."

The chassis is of the ordinary G.M. 2-ton type and the battery equipment consists of 60 type A8 Edison cells. An electric tower wagon of similar type had previously been put into service with equally good results.

FRENCH MARKET FOR ELECTRICAL GOODS.

Prior to the war a considerable amount of electrical goods was imported from Germany by French dealers in competition with other dealers handling French-made goods. It is thought that most of the inquiries in this line now come from the former class of dealers, who have lost their connections and who, naturally, have no claim on French manufacturers already represented. The French houses are more nearly fireproof than American houses and the same precautions do not have to be taken, so that American dealers exporting to France will have to furnish French patterns in several fittings that differ essentially from American practice. Among the more common instances will be: Bayonet sockets instead of screw sockets, tumbler switches instead of snap switches, sheet-metal tube with crimped joint and lined with treated paper instead of heavy metal conduit. This light conduit employs sleeve unions instead of screwed joints.

There have been inquiries regarding the conduit mentioned above, which is scarce in France at present. Other inquiries refer to: Multipolar snap switches, flush-type push-button switches, all fittings requiring hard rubber in their manufacture, high-candlepower low-voltage incandescent lamps for motion picture machines.

Editorial Comment

Index to Volume LXXIV Ready

THE index to Volume LXXIV of the ELECTRICAL REVIEW, comprising the 26 issues from January 4 to June 28, 1919, inclusive, is now ready for distribution. A copy will be sent to any subscriber upon request to the publishers.

Caution in Institute Changes

NUMEROUS changes in the activities of the American Institute of Electrical Engineers were discussed at the recent Lake Placid convention, as reported in this issue. These matters should be given most careful consideration and no hasty decisions arrived at without knowing that they meet the wishes of the great mass of the members and are for the good of the Institute. We urge special caution respecting any changes in the Institute's publications and doubt the wisdom of radical action on this matter.

Burglar Alarms Needed

AS LONG as we have inadequate police protection, crooked criminal lawyers, spineless judges and juries, we may expect a recurrence of raids on banks, paymasters and jewelers by daring automobile bandits. These victimized interests must therefore safeguard themselves as best they may. An excellent help in this line is a reliable burglar alarm. The bandits depend on their automobile for a quick escape. A speedy alarm is therefore an essential to their capture. A loud alarm sounded during the raid is likely to scare the criminals before they can effect their robbery, as has happened on several occasions where banks were equipped with reliable alarms. Electrical contractors can therefore aid the community by installing such alarms.

Economical Ore Handling

ONE of the principal reasons why the American iron and steel industry has forged ahead so rapidly is its very extended use of labor-saving machinery, nearly all of which is now being electrically driven. The use of motor drives in rolling mills and around blast furnaces and open-hearth furnaces has been frequently discussed, but the use of electricity in unloading ore vessels, while little less spectacular, is not so well known. In an illustrated article in this issue we describe the construction and operation of some gigantic electrically operated ore-unloading machines that have proven extremely economical in service. With two operators, one of these machines does the work that formerly took a small army of shovelers and barrow or truck pushers, and the work is done very expeditiously. In one case eight machines unloaded seven ore vessels totaling a load of 70,000 tons of ore within 22 hours. Such performances as these obtained through efficient, powerful machines electrically driven will keep our iron and steel industry in the forefront in the international competition for business in spite of high wages to the operatives.

Electric Brass Furnaces

FOR many years considerable attention has been devoted toward reducing the high loss of volatile metal that occurs in melting brass and cuprous alloys. One of the ways of reducing this loss, the latest and best, is to use the electric furnace instead of furnaces employing coal, oil or gas.

The huge demands for brass and its alloys created by the war resulted in effort being concentrated upon evolving a furnace that would do away with the extravagant waste of zinc in the process of producing castings and alloys. Out of this has come the electric brass furnace of today, of which there are a number on the market.

The electric brass furnace, like the steel furnace, represents a good load-factor and a comparatively heavy load. The capacity of the brass furnace is smaller than the steel furnace in units made so far, and there are many reasons why they may be expected to always remain so. There are many foundries scattered over the country—and we have often said before that the foundry is the one place where the electric furnace ought to be—where brass can be melted electrically with a big saving in zinc loss and all that goes with it.

Handling Competing of Merchandise

THE article by Mr. Thomas J. Casey in this issue contains some very interesting suggestions for the electrical contractor who is considering the establishment of a retail store. The recommendation that dealers do not handle competing lines of merchandise is well taken as the tendency in merchandising in the electrical industry is decidedly along these lines. Manufacturers are finding it desirable to give exclusive sales rights to jobbers who do not handle competing stocks, and likewise many jobbers are giving serious consideration to the policy of entering into agreements with dealers in different localities to represent them exclusively.

Electrical dealers can do no better than adopt the successful policies of the manufacturers and jobbers and benefit from their experiences.

It is well known that electrical appliances require intelligent selling, but little opportunity is given the salesman to exercise intelligent selling if, as in the case of a flatiron, the final choice between from one to a dozen different makes must be left to the customer. In spite of the great progress that has been made, the average housewife knows very little about electrical appliances. If a prospective purchaser enters a store for the purpose of buying an electric iron and asks the salesman which is the best, he is placed in a very difficult position if his house handles several different makes of the same size. It is far more satisfactory from every standpoint and undoubtedly productive of less confusion to be able to answer that one make has been selected as the most satisfactory for their customers and endeavor to make a sale on this basis. If the customer desires a particular make of product it can either be secured or it is better to have the customer go elsewhere.

The most successful retailers in other industries have almost universally adopted this policy of handling non-competing lines. It would be well for electrical merchants to give serious consideration to this matter.

The Progress of the Contractor-Dealer Association

ANYONE who has kept in touch with the activities of electrical contractor-dealers as reflected through the workings of the National Association of Electrical Contractors and Dealers cannot help but be impressed with the substantial progress that has been made by this branch of the industry during the past two years. Largely through the efforts of Mr. William L. Goodwin and his loyal supporters the electrical contractor has been rejuvenated, and today is also a progressive dealer rapidly adopting all of the modern principles of merchandising.

There are still many electrical contractors who refuse to advance and who were apparently satisfied with the chaotic conditions that existed a few years ago. And there are still so-called electrical dealers who maintain that the distribution of electrical merchandise should be confined to them, although they make practically no effort to modernize their business and keep abreast of the times. These same contractors and dealers are usually the first to complain of competition from central stations and others and to demand the same liberal treatment from manufacturers and jobbers. Needless to say, these contractors and dealers are the ones who most need the Association and it is hoped that the influence of the forthcoming convention at Milwaukee will reach out to these men.

In his notable address at the New Orleans convention two years ago Mr. Goodwin among other things pointed out that there is strength in numbers and that if the contractor-dealer fraternity desired to arrive at and maintain its place in the industry, it must build up a strong organization. The National Association of Electrical Contractors and Dealers has justified itself from every angle, and it will undoubtedly be but a short time before membership in the Association will characterize a contractor-dealer as one worthy of a place in the industry.

Service Costs and Rates

WHEN central-station service was in its infancy there was no knowledge of what it cost to furnish it and the rates established for it were set arbitrarily at such figures as were believed to insure at least a fair profit. For a great many years this condition continued, central-station companies making little or no attempt to ascertain what it cost to serve different classes of customers and often not knowing till the end of each year whether a profit or deficit had resulted from the year's operations. As a consequence of setting rates chiefly by guesswork, there were frequent discriminations not only between different classes of customers, but also among the customers of each class.

This condition was true likewise in the case of other utilities and was one of the causes that led to the adoption of commission regulation of public utilities. As such regulation has developed during the last dozen years it has been instrumental in bringing about a complete change in the making of utility rates. Instead of setting these arbitrarily without any consideration of the actual cost of rendering the service and charging as much as it was believed the customer would stand without quitting the service, it is now usual to make a careful analysis of the costs and then set the rates so that no class of customers is served at a loss and so that there is left enough margin over the cost to insure a reasonable return on the investment. Therefore, before discussing how rates shall be fixed it is necessary to study how the costs can be analyzed to show the various elements of cost affecting each class of service.

It is this order of treatment that has been adopted by Mr. H. E. Eisenmenger in his series of articles on "Central-Station Rates in Theory and Practice," which begins in this issue. Although part of this first article may seem elementary, it is necessary to know the fundamental principles before their application can be intelligently considered. These fundamental principles can be applied to any kind of utility service; for instance, the author shows their application to postal service—a branch of utility service that is claimed to be greatly in need of cost analysis. A preliminary study of the principles as applied to electric rates is also made in this installment, which will be carried out in detail in future articles of the series, which are to appear weekly, as announced in our last issue. We believe that, as we then stated, our readers will find these articles not only timely but highly informative. An introduction to the series written by Mr. S. E.

Doane, chief engineer of the National Lamp Works, with whom Mr. Eisenmenger was associated for some ten years in rate researches and investigations of similar central-station problems, has unfortunately not been received in time to be included at the beginning of the series. It will be inserted in due time, however, without seriously affecting the continuity of the articles. It is hoped, in fact, that it will add interest to the articles and emphasize the importance of thorough consideration of the subject.

Automatic Telephony Coming to Rescue

TELEPHONE companies are facing a problem of rapidly increasing difficulty in connection with maintaining their operating organizations in efficiency and strength. This is especially true of the larger cities. To train an operator to take care of her work properly and efficiently has usually required special instruction for several weeks or even months, and the large telephone companies have for many years been compelled to maintain, at considerable expense, operators' schools for training the large number of beginners continually needed to replace recurring gaps in the operating force.

There are several reasons for the forming of these gaps as soon as they are filled. One of the principal ones is that men readily appreciate a pleasant voice and courteous attention when it comes via wire, so much so that many even confirmed bachelors have fallen victims to the frequently unintentional charmer. In short, the percentage of marriages among telephone operators is probably higher than among any other class of gainfully employed young women. Strangely, however, this is not true of telephone operators in several other countries, for in a number of European countries it has become customary to keep spinsters and widows at operating work until they reach the ripe age of 70 or thereabouts. American operators' schools have perhaps been too efficient in developing in the girls not only courtesy and alertness but also amiability and poise.

Another reason for the gaps among operators is that most companies have not been able to pay very high salaries for the services of the operators, so that these remained on the alert for opportunities in other occupations that brought greater remuneration. Other girls found the work too strenuous for their nervous temperaments. The companies have tried to make the work less exacting and, by giving frequent rest periods and furnishing pleasant rest rooms and lunch rooms, have done their utmost to develop the welfare of the girls as well as their interest and pride in their work. But the gaps are no sooner filled than they open again so that there is a continual procession of girls training, working a short time and quitting. Needless to say, this high labor turnover is an expensive burden to the operating department and incidentally accounts very largely for justifiable complaints of poor service.

On top of these difficulties, which have become aggravated during the war because of the tempting salary offers in numerous other occupations, have recently come concerted demands for higher compensation, culminating in a strike in at least one city—Boston.

Over 25 years ago some of these difficulties were foreseen in the earliest inventions that aimed to replace the human element in telephone operating by means of automatic machinery. During the intervening years there have been great advances in automatic telephony. Several systems have been developed, of which at least one has come into quite extensive and successful use. The service rendered by the "girlless" 'phone is surprisingly prompt, free from wrong connections and cutoffs, and satisfactory in every way. It has been shown that there is no feature of telephone service that cannot be furnished through the automatic instrument; long-distance, information and emergency calls can be handled by a small number of operators. Foreigners unfamiliar with our language and people with impediments in speech can secure their connections much more readily than with a manual system. The perfected automatic telephone exchange equipment is a marvel of invention on a par with the linotype machine or printing telegraph and equally with these ingenious mechanisms a striking achievement in labor-saving apparatus.

It is not surprising, therefore, that the executives of the largest telephone companies have at last turned to automatic telephony to rescue their operating departments from their increasingly desperate situation. It has been understood to be the new policy of the large Bell companies to change over to automatic equipment those exchanges that have the heaviest traffic, incidentally making other rearrangements of offices, cables, etc., as would promote economy. It is not right to assume that these companies did not recognize the advantages of automatic telephony many years ago. They had a peculiar situation to face in that many millions of dollars of investment were tied up in their manual switchboards and the sudden change to automatic would mean not only losing much of this capital through discarding of the manual equipment, but also necessitate securing great amounts of new capital to purchase the automatic apparatus.

Now, however, because of the increasing cost of manual service, the economy in operation from adoption of automatic service will be greater and it becomes financially expedient to change over, since this economy will within a reasonable time offset the interest on the additional capital investment. Consequently, we shall see more and more use of the automatic telephone in our large as well as medium sized cities, this being but another instance of the use of electrical machinery to replace more and more costly and fickle manual labor—a development that is making rapid headway now and will continue to accelerate in the future.

Current Events

Plans for Contractor-Dealer Meeting—American Institute Discusses Organization—Trumbull Electric Changes Hands

LARGE ATTENDANCE EXPECTED AT MILWAUKEE CONVENTION.

Arrangements Completed for Nineteenth Annual Convention of National Association of Electrical Contractors and Dealers—Comprehensive Program of Papers.

Final arrangements have been completed for the nineteenth annual convention of the National Association of Electrical Contractors and Dealers, which will be held at the Hotel Pfister, Milwaukee, Wis., during the week of July 14. As previously announced in the ELECTRICAL REVIEW, Monday and Tuesday will be taken up by meetings of the Executive Committee, the first general session being on Wednesday morning. An address of welcome will be made by Gov. E. L. Philipp of Wisconsin and Chairman C. W. Peet will respond. An address on "Co-operation in Business" will be made by Frank B. White, of the National Agricultural Publishers' Association, and Frank Stockdale will speak on "Keeping Up with Rising Costs" at the afternoon session on Wednesday. The meeting on Thursday will be held at Waukesha Beach, the principal address being by W. L. Goodwin on "Merchandising Opportunities." A number of interesting reports and addresses dealing with various phases of contractor-dealer activities have been arranged for Friday.

The entertainment includes a reception and dance at the Hotel Pfister on Wednesday evening, sports and games at Waukesha Beach on Thursday afternoon, and an informal dinner on Friday evening. Announcement has been made that there will be special entertainment features for the ladies.

W. H. Morton, general manager of the Association, anticipates the largest attendance in the history of the organization.

CLOSING SESSIONS OF A. I. E. E. CONVENTION EMBRACE MANY SUBJECTS.

Discussions of Papers, Publication of Periodicals and Changes in Activities Some Topics.

The concluding sessions of the A. I. E. E. Convention at Lake Placid (the first two days' sessions were presented in last week's issue of the ELECTRICAL REVIEW) comprised discussions of papers and the making and discussion of proposals to change the existing mode of issuing Institute publications and broaden the activities of the Institute.

TRANSMISSION AND DISTRIBUTION TOPICS RECEIVE DISCUSSION.

After the presentation of the Transmission and Distribution Committee's report by E. B. Meyer on Thursday morning a spirited discussion on the dissipation of heat from cables and its effect on insulation took place. W. A. Del Mar spoke of the urgent need for specifications for paper and varnished cambric insulation. He recommended a study of the relative current-carrying capacities of cables in duct and earth. D. W. Roper emphasized the necessity of determining whether cables come up to A. I. E. E. specifications. P. M. Lincoln said that local conditions are so important that this problem devolves more upon the operating rather than the manufacturing company, and co-operation between the two is needed.

R. W. Atkinson said that copper temperatures may be determined when duct temperature, sheath temperature, cable load and characteristics are known. Professor Clark urged that funds be furnished to enable research to be carried on that will enable insulators of higher standards to be produced. C. P. Martin advocated that a standard method of testing high-tension insulators be adopted by the Institute.

H. R. Summerhayes pointed out that excessive heating of a few seconds from short-circuit currents may have a serious effect upon insulation. Colonel Jewett, of the Western Electric Co., spoke of research on insulating materials now being carried on under the auspices of the National Research Council. The success of this venture depends almost entirely upon the co-operation obtainable from the manufacturing and operating companies concerned. Dr. Steinmetz stated that, in his opinion, porcelain does not age; but it is the unequal expansion and contraction of the composite parts, namely, cement, porcelain and metallic pins, with temperature changes that is the seat of trouble in causing insulator deterioration. C. S. MacCalla told of an interesting experience of the Central Colorado Power Co. A large number of link insulators are used on the 100,000-volt lines. With this type of insulator, as distinguished from the cement-pin type, after correcting for failures from lighting, failures due to aging were only one-tenth of 1%.

The papers on "High-Tension Single-Conductor Cable for Polyphase Systems" and "The Dielectric Field in an Electric Power Cable" by W. S. Clark and G. B. Shanklin and R. W. Atkinson, respectively, were discussed by H. W. Fisher, Standard Underground Cable Co.; W. A. Del Mar, Electric Cable Co. and Habirshaw Electric Cable Co.; Philip Torchio, New York Edison Co.; D. W. Roper, Commonwealth Edison Co.; H. L. Wallau, Cleveland Electric Illuminating Co.

W. A. Del Mar presented a diagram showing electrical lines of force and heat flow around both sector-type and circular three-conductor cables. This showed that dielectric stress is about 15% greater in the round than in the sector type cable. The heat resistance from conductor to air is about 3% less for the sector than for the round conductor cable. The current-carrying capacity will be, therefore, from 1 to 2% greater than that of the round conductor cable.

Philip Torchio thought that Messrs. Clark and Schanklin were mistaken in saying that three-conductor cable is less advantageous than single conductor. Single-conductor leaded cables have a number of disadvantages, namely, the higher voltage impressed in the sheath with undergrounded sheath and the high charging current when the sheath is grounded. H. L. Wallau gave specific data as to sheath current and reduced voltages.

A. E. Silver's paper on the subject of "Problems of 220-Kv. Power Transmission," excerpts from which appear in this issue, brought out considerable discussion, the consensus of opinion being that such a voltage was practical, and that conditions already exist where systems similar to those proposed could be adopted.

W. S. Murray, formerly electrical engineer of the New Haven Railroad and conservation engineer for the government, in the discussion referred to a superpower line which is proposed between Washington and Boston to serve a territory measuring about 450 miles long by 150 miles wide as a concrete opportunity for application of 220 kv.

A. F. Bang said 220,000-volt transmission lines without spare transformers is considered unwise. He favors single-phase transformers in preference to large three-phase transformers for this service. He also questioned whether external cooling of transformers is justified in every case.

F. W. Peek, Jr., expressed the belief that a line built according to the plan outlined in Mr. Silver's paper would be more reliable than present 33,000-volt lines, and that link-type insulators will overcome most objections to insulators.

J. F. Peters spoke of several factors which being of no consequence at low potentials become serious in the design of high-voltage apparatus, one of which was electrostatic field. Short-circuit stresses will be less severe on high-tension transformers because of the greater magnetic leakage.

A number of speakers favored grounding the neutral of Y-connected systems. Others taking part in the discussion were Philip Torchio, New York Edison Co.; H. B. Dwight, Canadian Westinghouse Co.; A. F. Bang, Pennsylvania Water & Power Co.; S. Warren Mauger, R. M. Spurck and F. F. Brand, General Electric Co.; G. I. Gilchresh and R. P. Jackson, Westinghouse Electric & Mfg. Co.; J. C. Clark, Stanford University; C. F. Harding, Purdue University.

Technical Committees to Have Wider Field of Activity.

Wilfred Sykes, chairman Board's Committee on Technical Activities, stated in his report that the technical committees might to advantage do more than arrange for the presentation of papers, that is, in addition collecting and correlating data, formulating rules, etc. As this sort of work requires considerable time, it would be necessary for committee members to hold office for a longer period of time than one year, as at present. This line of thought was continued by Dr. Steinmetz, who said that the chief value of committees is to supply extensive reviews of developments in their special branches of science or applied science, in such form that it is get-at-able. He made mention of the reports of the N. E. L. A. and the Association of Edison Illuminating Companies, stating that such reports are much more desirable than individual papers. The presentation of individual papers should be made to assist final committee reports, which ought to be more full than is now generally the case. Such a scheme of things would broaden engineers. Only workers should be retained on committees.

Prof. Karapetoff suggested that a research committee be established to act as an intermediary between the National Research Council and the A. I. E. E., taking up individual problems that come up before the technical committees. As the best work is done by individual geniuses rather than by committees, Prof. Karapetoff thinks it inadvisable to dispense entirely with individual papers. David B. Rushmore said that one of two purposes is open to the A. I. E. E. One is to supply every electrical engineer with information he wants. The other, to allow specialists to form separate organizations. The question, therefore, is whether the Institute should enlarge its activities and become an inclusive body or confine its attention to those engineers who are not specialists and become a residual body. He suggested that section chairmen recommend eligible committeemen stating their connections and abilities for work. The performance of each committeeman should be recorded, that the inactive members may be dispensed with. L. W. Chubb offered an alternative method, namely, to select each chairman from the preceding committee, choosing the remaining members on the basis of their former activity.

Discussion Centers Round Development Committee's Report.

The presentations made by the Development Committee in which it was proposed to modify and extend the present activities of the Institute, received a large amount of discussion. Calvert Townley, chairman, pointed out that the principal proposals comprised the substitution of the present monthly proceedings by an engineering periodical; the creation of geographical sections, each represented by a vice-president; rotation of monthly meetings instead of holding them at New York City; federation of local engineering for better co-ordination under national council; holding of regular engineering congress, and decentralization of work. It is proposed to eliminate the publication of Institute papers other than those presented before the general meetings, and papers presented before sections will be abstracted. Articles of general engineering interest and abstracts of papers presented before allied associations will be included in the publication that has been proposed to substitute for the monthly proceedings.

In the discussion on this matter of the Institute periodical, the consensus of opinion seemed to be against doing anything that would tend to lower the present high standard of the Institute's status and its publications. Dr. Steinmetz said he would very much regret seeing either the size or the quality of the Proceedings changed after having retained their present form for 35 years. The proposal to change the form of periodical instead of the publication as issued by the Institute would undoubtedly lower the prestige of the Institute, while soliciting advertising would have many drawbacks. Without adopting the radical steps proposed, it was his opinion that a portion of the $18,000 now expended in binding the transactions could be saved in other ways.

Mr. Vincent, who was supported by Prof. Clark, suggested that it would be better to increase the revenue rather than to curtail the expenditure in the way proposed. He suggested that this might be done by elevating the membership of those persons now below the rank to which they are entitled. Prof. Clark suggested that the cost of binding the transactions should devolve upon the members. L. T. Robinson pointed out that the Institute papers are the most interesting part to many members at present; that young engineers do not have to be attracted by popular articles; and that it was not the intention of the proposed Institute organ to parallel the work of existing engineering periodicals. Mr. Chubb expressed it as his opinion that it would be a great pity to change the present type of technical papers. He failed to see how popularized or generalized papers would be able to supplement present technical ones if a monthly periodical is to be maintained.

Prof. Karapetoff, speaking very strongly, said it would be suicidal for the Institute to adopt any course with a downward trend. The present high standing of the Institute should be maintained. Popularized and generalized information is well taken care of by the present engineering publications that are alike available to everybody. If a publication such as the Development Committee proposed was to be issued, it would have to compete with technical papers now issued by skilled and shrewd business men whose business is publishing and who are equipped with stable and liberal personnel. Dr. Steinmetz pointed out that papers presented before the Institute should be of the highest calibre. Mathematical and theoretical papers are the ones which give prestige to the Institute and permanent value to the Transactions. Inventions, discoveries and developments; theoretical and experimental investigations; and the operation and installation of equipment should also be subjects for discussion so long as they represent the forward step. He suggested that it would be of immense benefit if all papers of affiliated societies could be made available in condensed form. Papers might be accepted on the basis of their abstract value.

A vote was then taken to accept the proposals regarding an engineering publication, as submitted by the Development Committee. President Adams, Philip Torchio and others expressed themselves as being strongly opposed to the inclusion of advertising matter in the Institute's Proceedings.

C. G. DU BOIS NOW PRESIDENT OF WESTERN ELECTRIC COMPANY.

Succeeds H. B. Thayer, Who Retires After 33 Years to Become President of American Telephone & Telegraph Co.

At a meeting of the Board of Directors of the Western Electric Co. held on July 1, Charles G. Du Bois was elected president of the company to succeed H. B. Thayer, who has resigned after 38 years of service to assume the presidency of the American Telephone & Telegraph Co., as announced in our issue of June 28. Mr. Thayer was elected chairman of the Board of Directors of the Western Electric Co.

Mr. Du Bois was born in 1870. After his graduation from Dartmouth College in 1891, he joined the Western Electric Co. in New York City as a clerk in the accounting department, and in 1896 he was appointed chief clerk at the New York office. In 1898 he was elected secretary of the company with offices at Chicago. This work carried with it a general supervision of the entire accounting system of the Western Electric Co.; and in this connection Mr. Du Bois was largely instrumental in working out and securing the adoption of the company's first pension plan.

Shortly after assuming the duties of secretary, Mr. Du Bois was also made supervisor of branch houses. This carried with it the opening of a large number of distributing houses, which are now a part of the company's organization.

In 1907 Mr. Du Bois was transferred from the Western Electric Co. to the American Telephone & Telegraph Co. as its comptroller. In this capacity he inaugurated and supervised a new and comprehensive system of accounting for the Bell Telephone System. In 1917, shortly after the entry of the United States into the war, he went to Washington to serve as comptroller for the American Red Cross. After systematizing the Red Cross accounting work and organizing a department to carry it on, he resumed his duties with the company.

On Oct. 1, 1918, Mr. Du Bois rejoined the Western Electric Co. as vice-president, which office he held until his accession to the presidency. Mr. Du Bois' long association with Mr. Thayer in the administration of the company insures a continuity of policy and methods in the conduct of the business.

Chas. G. Du Bois, the New President.

H. B. Thayer, Retiring President.

TRUMBULL ELECTRIC REPORTED AS SOLD TO GENERAL ELECTRIC.

Trumbull Electric Manufacturing Co., of Plainville, Conn., to Form Part of General Electric System—Plant to Be Enlarged.

According to a reliable Hartford, Conn., newspaper, control of the Trumbull Electric Manufacturing Co., Plainville, Conn., has been acquired by the General Electric Co. The capital stock of the Trumbull company has been $500,000 and its surplus about as large. It is stated that the General Electric Co. will increase the capital, enlarge the plant and greatly extend its business.

The Trumbull Electric Manufacturing Co. is one of the best known manufacturers of switches, panelboards, switchboards and other electrical supplies. It has been very successful since its modest beginning in 1899, when the three brothers, John, Henry and Hugh Trumbull, opened a small factory in an abandoned barn in Plainville; the capital invested was about $250 and six or seven workmen were employed. Within a year the company replaced its wooden factory with a more pretentious brick building and increased its employes to about 40. At present the plant consists of two large four-story buildings with a connecting building of the same height. It is the principal industrial establishment of Plainville and has employed about 500 workers at the time of maximum activity during the war.

Of the Trumbull brothers, Hugh sold his interest in the company several years ago and organized the Trumbull Automobile Co., Bridgeport, Conn. He lost his life in the sinking of the *Lusitania* by a German submarine on May 7, 1915. During the last five or six years Henry Trumbull has been in poor health and has more and more retired from active participation in the business, which has devolved almost entirely upon John Trumbull. The secretary of the company is Stanley Gwillim, who has been associated with it for some 15 years.

WESTERN CENTRAL STATIONS COMPLETE POWER DEAL.

Pacific Power & Light Co. to Tie In to Large Transmission System of Montana Power Co.

According to recent press dispatches, the Pacific Power & Light Co., at Yakima, Wash., has completed arrangements with the Montana Power Co. by which the former will tie in to the big transmission line of the latter company at Lind. This connection will practically double the capacity of the Pacific Power & Light Co.'s plant.

The transmission line of the Montana Power Co. extends from near Billings, Mont., to Seattle, Wash., one of the longest in the world. The transmission voltage is 110,000 volts, which will be stepped down to 66,000 volts for use by the Pacific Power & Light Co. It is expected that during the height of the irrigation season the demand will be about 20,000 hp.

RAILROAD ELECTRIFICATION IN CHICAGO TO BE BEGUN.

Illinois Central to Electrify Suburban Lines First—Part of Big Lake Front Improvement Project.

Railroad electrification in Chicago, the largest railroad center in the world, is likely to begin within a few years in accordance with an agreement concluded by the Illinois Central Railroad, the South Park Commission and the Railway Terminal Committee of the Chicago City Council. The Illinois Central suburban lines are to be electrified throughout within 7 years, the remainder of its trackage north of Twelfth street within 10 years, and all the rest of its passenger and freight tracks within 15 years. The ordinance covering this matter relates to it only as one feature of a very extensive improvement, providing, among other things, for filling in a stretch of Lake Michigan about six miles long by one-half mile wide just east of the railroad tracks, this filled section to form an outer boulevard and parkway connecting Grant and Jackson Parks. The railroad's right-of-way will be widened and it will be relieved of the need of protecting the shore line along its tracks. A new terminal depot, to accommodate several other railroads also, is to be built by the Illinois Central south of its present Park Row station, which will be torn down and its site added to Grant Park. Numerous incidental improvements to be made by the railroad will make its total expenditure for the entire project in the neighborhood of $88,500,000. The South Park Commission will expend about $30,000,000 for the park improvements.

Conspicuously located on the lake shore, the Illinois Central Railroad's Chicago terminal lines have been attacked for many years because of the smoke and cinders emitted in front of one of the best residence and hotel districts in the city. Improvement associations, women's clubs and other organizations have sought to force electrification of these tracks. An outcome of this was a movement for railroad electrification throughout the city, involving a total of about 4000 miles of single track. This was dropped some years ago after an exhaustive report by a special commission showed the expense to be extremely high. The Illinois Central negotiations indicate that the city's electrification policy will be to bring about electrification not on a wholesale scale through a general ordinance but by means of special contract ordinances with the individual railroads as opportunity offers. The present ordinance needs the formal approval of the City Council and the Federal Government, which is assured in each case, according to the most reliable reports.

CO-OPERATIVE COURSE IN ELECTRICAL ENGINEERING TO BE GIVEN.

Massachusetts Institute of Technology and General Electric Co. Arrange Five-Year Course.

An electrical course is to be conducted by the Massachusetts Institute of Technology in co-operation with the General Electric Co. and will afford a distinctive training for the technical and executive responsibilities of the manufacturing industries. The course will cover a period of five years, of which the first two are to be identical with the old and well established course in electrical engineering at the Institute, and the last three are to be divided between instruction at the Institute in Cambridge, Mass., and experience associated with instruction at the West Lynn and other works of the General Electric Co. The work of the final year of the course will be of advanced nature, with emphasis laid on the problems of administration, the design and development of the engineering projects, and in creative work such as research. The training at the works of the General Electric Co. is laid out and will be conducted with a view to the maximum educational value and is intimately correlated with the instruction at the Institute.

The co-operative training which occupies the last three years of the course will be entered upon by the new class on October 6, of this year. The successful completion of the course will lead to the degree of Master of Science. The number of men who may be admitted each year is at present limited to forty, and candidates for admission are subject to the approval of both the Institute of Technology and the General Electric Co. Students who have successfully completed the first two years of the electrical engineering course of the Institute of Technology are eligible to enter this co-operative training, and well qualified students who have completed the substantial equivalent at other institutions are also eligible for admission.

While students are at work at the General Electric Co. plants they will receive regular compensation but are to be under supervision of teachers and their work in the shops is to be supplemented by conferences with works department heads in which technical and administrative problems arising at the works will be discussed.

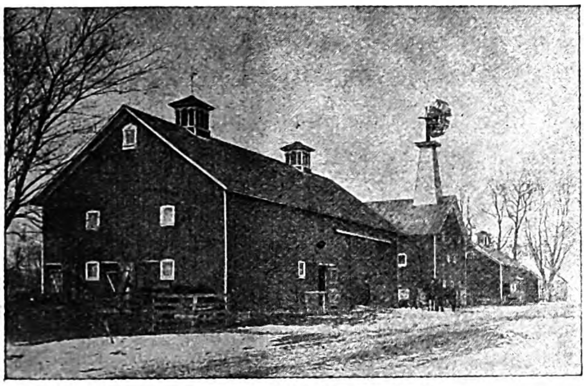
Commercial Practice

Model Farm Electrification—Hospitality of Dayton Utility —Summer Sales by Mail—Summer Appliance Sales

ELECTRICITY HELPS PROGRESSIVE IOWA FARMER.

J. W. Oltrogge, Near Readlyn, Makes Varied Uses of Current Purchased from Distributing System.

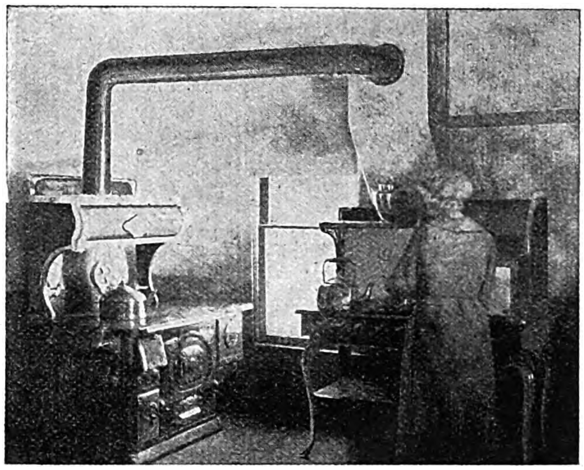
Farmers in Blackhawk County, Iowa, demonstrate emphatically that the use of electricity is just as much a matter of economy and convenience to them as it is to the millionaire in his "model farm." Farmers in this neighborhood on farms of all sizes have electricity lighting their house and buildings, pumping water, grinding feed, and running the dairy machinery. One of the most complete installations is that of J. W. Oltrogge, who lives near Readlyn.



Barns and Stables Electrically Lighted, As Are All the Farm Buildings.

As will be seen from the illustrations, Mr. Oltrogge's buildings are all of first-class construction, and are electrically lighted throughout. Over the door of his garage is a lamp which lights the walk from house to barn, and is controlled from four points. Thus there is no need of a lantern, as the light can be turned on at the house, and extinguished on reaching the barn. In the barn is a 7½-hp. Westinghouse motor driving a Bowser feed mill. Experience has shown just where to set the slide gate in the feed-chute so that the mill gets just enough unground oats and corn, and so it runs without attention. Nearby is a 1-hp. motor belted to a shaft formerly driven by a windmill. This shaft runs outdoors to a pump which delivers to a concrete tank from which pipes run to various watering troughs. One of these troughs which serves the beef animals, is placed in the wall of a shed so that it can be reached from without or within. Formerly there was trouble with this freezing, but Mr. Oltrogge has put in a little electric immersion heater, taking 500 watts, which effectively keeps the water ready to drink. Since there are about 150 head of cattle the saving of this device is obvious. The motor-driven feed cutter, too, means no hauling of feed over heavy roads, and no shortage of ground feed at any time.

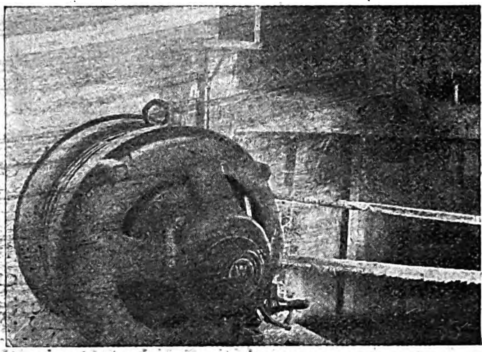
A Light Over the Garage Door Makes It Easy to Go About at Night.



An Electric Range Replaces Coal in the Kitchen.

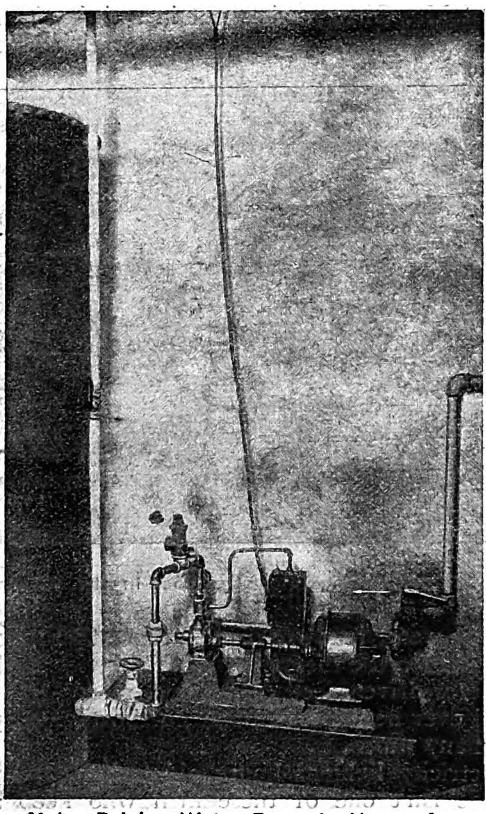
Electricity lightens household tasks too, and Mr. Oltrogge isn't one of these men who keep all the conveniences for himself. His house is well lighted throughout, and has a complete plumbing installation, supplied by a small rotary pump driven by a Westinghouse ⅓-hp. motor. This pump delivers into a 3-ft. by 6-ft. pressure tank. In the laundry is a combined washing machine and wringer driven by a ¼-hp. motor. In summer Mrs. Oltrogge's kitchen is always cool for she uses an electric range. This has three heating units on top and an oven underneath. In winter, too, there is no fear of fuel shortage, and no delay should the range fire go out. Other household equipment is an electric flatiron, a sewing-machine motor, and an electric vacuum cleaner. In the garage is a motor-driven grinder which keeps tools sharp.

Mr. Oltrogge has a farm of 320 acres, on which he usually feeds 150 head of cattle and 300 hogs. His electricity bill totals $8 to $10 per month. Current



A 7½-Hp. Motor Drives Feed Cutter.

is purchased from Tegtmeier Brothers, who operate a 2300-volt distributing system. As is customary in this community, each user pays for his share of whatever line connects with the nearest distributing line. He also pays for his transformer (in this case a 7½-kw. unit) and protective devices. Tegtmeier Brothers install the meters. The rate for current



A ⅓-Hp. Motor Driving Water Pump in House, for Farm and House Services.

decreases with the amount used, thus making it easy for the farmer to run several motor-driven devices. By their aid it is possible for Mr. Oltrogge with the help of one boy, to take care of his stock during the winter alone and in the summer to concentrate his time on really productive work. The saving from this is very high, reducing not only the cost of farming, but the work of catering to farm hands. The farm of Mr. Oltrogge is one where the housewife's work is reduced to a minimum.

DAYTON COMPANY'S HOSPITALITY ENJOYED BY 1400.

The Dayton Power & Light Co. held its eleventh annual picnic Friday, June 27, at Overlook Park. It was by far the best picnic ever held by the company. The events during the afternoon were thoroughly enjoyed and a large number of prizes were awarded.

The ball game between the power stations and the office and sales teams was a very exciting contest and was won by the office and sales, score 7 to 6. The F. M. Tait loving cup was awarded to the office and sales, they securing the greatest number of points in the different contests.

The O. H. Hutchings loving cup was awarded to Earl Compton of the meter department, as being the best all around athlete.

Dancing until 11:30 finished out the day. Music was furnished by the Park Orchestra. The committee in charge was Charles Garman, Burt Taylor, Frank Jones, Joe Gunzelman, W. L. Andrews, Richard Wuichet, Frank Kendig, Carrie Daum, Ralph Scherer and Fred Lewis.

JULY TO BE SEASONAL OPPORTUNITY FOR FLATIRON CAMPAIGN.

With a reduction in electric light rates effective July 1, and a reduction in the cost of the Western Electric 6½-lb. flatiron from $6.50 to $4.90 as incentives—in which the hot weather also is a powerful ally—the Duquesne Light Co., has set out to sell 2500 electric irons during the month of July.

During July, 1917, the company during a similar campaign sold 1776 flatirons. This year they will not be satisfied unless it sells 2500. Every employe is asked to attempt to sell at least one iron, which if they succeed, assures the campaign "going over the top." In the publicity being accorded the campaign special emphasis is being placed upon the fact that the electric flatiron is ideal for the summer months when the temperature is high and the air humid. The cut in price and the lower energy rates are also being featured. The campaign is in charge of P. H. Simon, manager, Electric Shop, Duquesne Light Co.

ELECTRICITY IN AGRICULTURE GIVEN IMPETUS IN ENGLAND.

The recently issued annual report of the British Conjoint Board of Scientific Societies contained further reference to the proposal of the Committee on the Application of Science to Agriculture that the Board of Agriculture should grant funds for designing, constructing and testing practically an electrical tractor and certain other agricultural machines. On the occasion of a deputation to the permanent secretary it was urged upon him that big electrical developments were to be expected both in the supply of motors for homestead purposes and also upon the land. Sir Daniel Hall gave a sympathetic hearing and agreed that much was to be expected in agricultural operations from the future use of electricity but he thought the time inopportune. If manufacturing firms would set about the design so as to be ready at a later and better moment he would deal with the matter then. Sir John Snell presented a development scheme for the supply of electric power to the farms of a district at Bridlington in Yorkshire, which contained 1177 farms of various sizes.

Operating Practice

Cleanliness of Turbogenerators — Dielectric Losses of Cables — Oil Switch Explosions — Rates of Steam Making

SPARKS AS WELL AS ARCS CAUSE TURBO-GENERATOR FIRES.

Cleanliness Precaution Against One Form of Fire.

Short circuits internally have resulted in turbogenerators catching fire and destroying themselves. Proper relay protection so that a machine in trouble is quickly isolated and the air supply shut off do much to prevent internal fires starting, or if started, from spreading.

However, not all fires are due to heavy-current arcs. Many result from dust and dirt that has collected in the windings, this accumulation of combustible material acting as tinder to a spark. A spark may occur from a number of causes. On the other hand, a spark will probably do little damage if the surfaces of the windings are clean and free from such materials as oil, dust, grease and pieces of cotton waste, etc., which are combustible and may be inflammable. It is well to take precautions against internal turbogenerator fires. It is well to furnish means for fighting these fires should they take place. But it is also well to make some effort to keep the machines clean internally by conditioning the air—which also increases the capacity of the machine—and by not allowing cotton waste and lint to be used for wiping purposes around these machines. By following these simple precautions sparks will create little hazard.

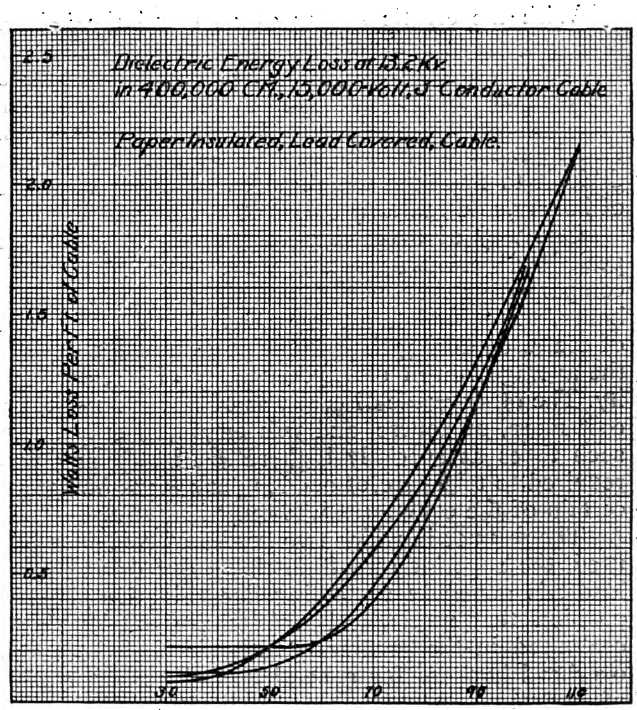
CLAUSE IN CABLE SPECIFICATIONS CARES FOR DIELECTRIC LOSSES.

Maximum Dielectric Loss with Temperature Increase Guaranteed.

Much attention has been given the matter of underground cable rating of recent years because of the growing importance of this phase of transmission and the effect that cable failures have upon life of cables, reliability of service and investment required to give reserve and safe capacity.

It is well known that at the higher potentials, the decrease of dielectric resistance with increasing temperature is such that above a certain temperature, the dielectric losses due temperature are such that although load current ceases, the resistance of the dielectric is such that the losses due the potential through the dielectric are sufficient to cause eventual breakdown resulting from the cumulative effect of temperature upon dielectric strength. One way in which this increasing dielectric loss can be prevented is by keeping within the safe dielectric temperature range. Another method employed is to exceed this limit when necessary and then disconnect the cable from the potential until the cable cools off.

The dielectric properties of a cable decide the safe operating temperatures of that cable and determine at what temperature the cumulative effect of the dielectric loss will cause dielectric failure. One large central-station company has already added clauses to its underground cable specifications requiring cable manufacturers to submit with their bids a table or curve guaranteeing values of dielectric loss that will not be exceeded under various temperature conditions. With this data on hand, and with the help of a temperature



Curves Showing Watts Loss Per Cable-Foot at Different Temperatures. Paper-Insulated, Lead-Covered, 15,000-Volt, 3-Conductor Cable. Applied Potential of 13,200 Volts.

survey made of the cable duct routes, it is possible to very closely determine the safe loading of the various cables, in this way obtaining full safe current densities and at the same time reduce cable breakdowns and service interruptions from this cause to a minimum.

OIL FUMES MENACE TO OIL CIRCUIT-BREAKERS.

After repeated operation, such as may occur in closing a circuit several times on a short-circuited line, oil circuit-breakers sometimes blow up. This happens with circuit-breakers operating not only at the higher voltages but also at potentials in the neighborhood of 2300. The cause of these explosions, while they may sometimes be due to the breakdown of the switch bushings, is usually that an oil vapor has collected above the oil, and this, becoming ignited, has resulted in the explosion and the tearing off of the oil-switch tank.

The collection of oil vapor can be prevented by maintaining a circulation of air above the oil level; this is done in one instance by the use of a vent or valve, which closes before the switch opens. However, for those circuit-breakers where provision is not specially made to prevent the collection of oil vapors, it is a wise measure to refrain from closing them more than necessary in quick succession on short circuit. In any case it is well to examine switch contacts after the switch has repeatedly functioned in rupturing heavy currents.

FACTORS INFLUENCING RATES OF STEAM MAKING.

Partitional Hoppers, Stoker Arrangements and Mechanical Draft Are Involved.

By W. H. De Muth.

With the erratic supply of coal and the inferior and dirty grades available during parts of the war, came many innovations aiming to overcome some of the difficulties involved. One of the greatest difficulties was due to the high dirt and non-combustible content in the coal, a condition that made it extremely difficult to maintain the required steaming capacities of boilers, and radically curtailed overload capacity.

One way of overcoming this situation during the peak load periods that take place almost daily for a comparatively short period, namely, for about 1½ to 2 hours, was to maintain two grades of coal. The grade of coal used during the greater portion of the day was the average run of coal, presumably of inferior quality. The other grade of coal was of better quality, and cost more, of course, and was employed only during such times as specially high rates of steaming were required to take care of sudden peak loads or because certain of the equipment was out of service.

The manner in which two grades of coal have been used, the superior coal for helping out during heavy loads, is generally something like this: On the supposition that mechanical stokers are employed, the coal used in the greater quantity is loaded into the overhead hoppers for general use. The better grade of coal, costing more, more difficult to obtain, and used only for short periods of time, is dumped on the boiler-room floor. A pile is "spotted" at each stoker, in the middle of the boiler-room aisle. When the sudden demand for steam comes on, or just as it is about to come on, the firemen commence shovelling the coal from the floor into the bins immediately above the stokers.

The above practice is followed by many small companies, and also by one of the largest utilities in the country. But the policy is not altogether the best one to follow, as can be shown by the following.

Two-Part Coal Hopper Has Merits.

At best, in most generating stations only a few of the total boilers installed are required to be supplied with the higher grade of coal. Instead of dumping this coal upon the boiler-room floor in front of these boilers it would be very much preferable to have subdivided coal hoppers—hoppers with compartments in them, for a certain number of the boilers installed. One of these compartments of each hopper could be smaller than the other, if the use of the more expensive coal is not large compared to the use of the inferior grade of coal.

This arrangement has the very real advantage that the good coal is available for any emergency immediately on notice irrespective of men available or maintaining a reserve of firemen, the boiler-room floor is not littered up and difficulties as to moving the coal and dispatching the coals do not occur. With the divided coal hopper both grades of coal can be handled efficiently; both grades of coal are on hand ready for immediate use without calling for any additional outlay of labor.

Two Types of Stokers Instead of Two Grades of Coal.

However, there is another way of obtaining higher steaming rates than by adopting two grades of coal. Using two different coals complicates plant layout, bookkeeping, labor and the keeping of station data. Moreover, coal deliveries become more complex and station performance is entirely dependent upon two different coal deliveries instead of one, a condition that in this case does not improve reliability but tends to reduce it.

A better way of changing the steam-making capacity of boilers than to resort to two different grades of coal is to employ two different types of stokers. Doing this means that the rates of combustion are changed instead of changing the calorific value of the fuels. Use of two different types of stokers seems to be the scientific method of enabling existing stations to take care of peak loads and emergencies when inferior grades of coal only can be obtained.

For illustration, take a typical example. Many plants are equipped with chain-grate stokers, a type of stoker that employs natural draft, although be it said there are several forms of this stoker now on the market that utilize mechanical draft. A chain-grate stoker is well adapted to burning certain coals. But it also is not able to increase its rate of combustion above a certain limit, about 250%, without getting into trouble and resulting in loss of economy. On the other hand, the underfeed type of stoker is able to go from normal to 300 and even to 400% of rating on short notice and for periods of time that are usually sufficient for the ordinary emergency. A station containing chain grates and underfeeds is flexibly adapted to handle change in coal and change in load.

The use of two types of stokers has many advantages. At the same time such an innovation necessitates considerable expense and takes time. There is still another practice that may be adopted in some cases and one that while being less expensive initially and less radical than the use of two different types of stokers, is also flexible in results. Reference is made to the use of mechanical draft under some of the existing stokers.

A stack is the least flexible way imaginable of controlling draft. One is placed unmercifully at the mercy of climatic conditions. If sufficient draft is furnished to take care of high ratings, by the design of the stack, air infiltration and waste of coal are to be expected at normal loads. On the other hand, a stack designed "close" will be found to introduce serious limitations when higher rates are urgently needed. Mechanical draft makes one independent of the weather and largely immune from troubles incident to varying grades of fuel. It answers immediately to the demands for higher rates of steaming. The most efficient and economical arrangement is that where natural draft can be utilized during normal and light loads and mechanical draft during the heavier loads and forced ratings.

Contracting-Construction

Wiring Ampere-Hour Meter for Tractors — Banks Need Burglar Alarms — Trade Acceptances in Building Work

CONNECTING CHARGE-CONTROLLING AMPERE-HOUR METER FOR TRUCK.

Use of Special Trip Conductor in Charging Plug and Cable to Terminate Battery Charge Automatically.

Success in the use of electric industrial trucks and tractors depends chiefly on the care that is given to the storage batteries that furnish the current for operation. Of special importance is it to charge the battery completely after it is wholly discharged and yet not prolong the charge excessively after it is time to cut it off; because this means not only waste of energy, but may damage the plates on account of the violent gasing from heavy current at the end of charge. If the truck or tractor has not been heavily used when it comes time to charge it again it will not require as much charge as one that was in continuous use during the day. Consequently there are apt to be various states of discharge among the trucks put on charge at the end of the working day and these trucks should each receive a charge proportioned to the service it rendered since it was last charged.

Doubtless the best way to insure this is to provide on each truck, tractor or industrial battery locomotive an ampere-hour meter with zero contact point. Such a meter has the added advantage that it permits the driver to see at a glance just how many ampere-hours of useful charge he has left in his battery at any time while in service so that he is not likely to run it to exhaustion and be stalled at an unfavorable point. Ampere-hour meters for this service are built so that they record how many ampere-hours have been discharged while the truck or vehicle is in operation. When the outfit is put back on charge the indicating hand proceeds to move back to zero, but at a slower rate than during discharge; this is to compensate for the inefficiency of the battery—that is, because it needs to have more energy put back into it than was taken out during charge. Usually about 15% more charge is needed, in the case of lead-type storage batteries, than was obtained on discharge, although this percentage is usually adjustable within certain limits to permit of an occasional extra long overcharge.

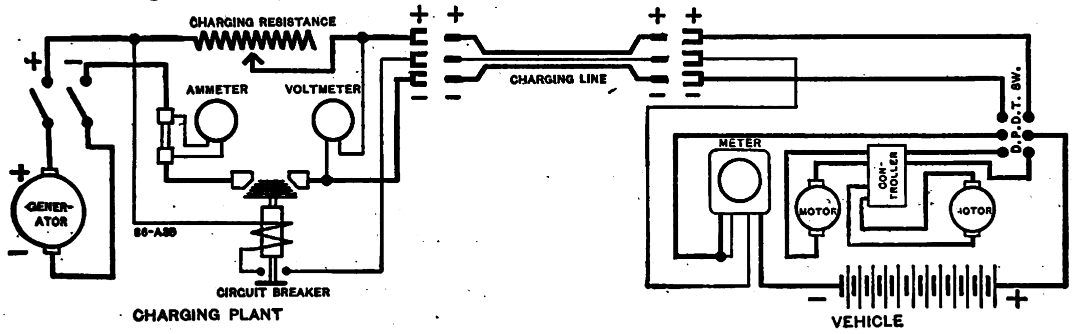
The connection by which this automatic cutoff is obtained is shown in the accompanying diagram. The heavy circuit connected to the meter is the series charge or discharge circuit. Two lighter wires also are connected to the meter. These form part of the potential or shunt trip circuit of the circuit-breaker on the panel of the charging plant. One side of this shunt circuit is connected just below the meter to the opposite side of the main circuit from that to which the other end of the breaker's trip coil is connected. The other light wire in the meter leads to a contact that is tripped when the indicating hand returns to the zero point. When the needle so returns it opens the trip circuit and the breaker then opens the charging circuit. The breaker also serves as a no-voltage cutoff.

In connecting this meter it is necessary to use a three-pole charging plug and charging cable; one wire in the latter and one terminal in the plugs and receptacles may be somewhat lighter, since it serves merely to carry a very small current. The diagram also shows the general method of connecting up the entire charging and vehicle circuits. The diagram was prepared by the Sangamo Electric Co., Springfield, Ill., which has just put out a new type of ampere-hour meter of rugged construction for truck and tractor service, a detailed description of which was published in our issue of last week.

BANK ROBBERIES SHOW OPPORTUNITIES FOR INSTALLING BURGLAR ALARMS.

Electrical Contractors Can Come to Relief of Smaller Bankers Who Are Being Victimized by Automobile Bandits—Requirements of Reliable Alarm Systems.

Numerous bold robberies of banks in the smaller towns and in the outlying parts and suburbs of large cities have again called attention to the need for installation of reliable electric burglar-alarm systems. Only a few years ago, at a time when there was a similar epidemic of handit raids, the Illinois Bankers' Association recommended to its members that they install a good alarm system in each of their banks, since it had been shown that this served in several



Wiring Diagram of Typical Installation of Automatic Charge-Controlling Ampere-Hour Meter on Battery Trunk, Showing Circuit-Breaker on Charging Panel Controlled by Meter Contact at Full Charge Point.

cases to scare the robbers before they could seize any booty and caused them to turn and flee in order to escape capture; in other cases it led to capture or shooting of at least part of the gang while they were attempting to escape. Only a week ago a case occurred in Chicago in an outlying bank in which a gang of automobile bandits attempted to hold up the bank, which was well equipped with burglar alarms. The alarm was set off by one of the tellers pushing one of the numerous push buttons without attracting any attention and ringing of the gongs aroused the neighboring merchants as well as scared the would-be bank raiders so that the latter hastily concluded to flee if they were to escape almost sure capture or death.

Some years ago the opportunity for reliable contractors installing dependable alarm systems was pointed out in these columns. It is not necessary to dwell on the value of such systems to banks not otherwise well guarded. Any contractor with a good reputation in the community can readily convince his own banker, if not other bankers of the town, of the importance of having a good alarm system as a safeguard against loss and of not trusting to luck in warding off a bold attack.

A dependable system means, first, a closed-circuit system, because any open-circuit alarm can be too readily put out of order by cutting of the wire at any point on the circuit. As an additional precaution the wiring of the battery and bell sections of the system should be in conduit to prevent tampering. All push buttons, of course, must be of the closed-contact type and be well distributed throughout the establishment so that no matter where the tellers or clerks may be when the raid is attempted or how few attendants there are in the bank at the time it will be possible to operate a button easily and without attracting attention. Obviously, the buttons must be located so that they will not accidentally be pushed, as that would cause needless and annoying alarm.

All alarm bells and gongs should be of big size and continuously ringing type so as to sound a vigorous and prolonged alarm. Preferably, one of them should also be installed in front of the bank, this being a weatherproof gong, of course; this outside gong will serve to arouse the neighbors. If it is not easily possible to connect the system to the police headquarters, it should at least be possible to arrange one, two or more telephones so that the receivers will be pulled off their hooks readily; then the telephone operator will hear the commotion and notify the police, constable or sheriff of the town.

Banks are not the only places that need such protection. Paymasters' offices in factories and other plants, jewelers, stores and other establishments where money or valuables are likely to be kept need similar alarm systems.

TRADE ACCEPTANCES COVERING BUILDING OPERATIONS.

Federal Reserve Board Not in Favor of Extending Acceptances to Cover Labor Alone in Building Contracts.

The Federal Reserve Board has received various inquiries with reference to the right of the various parties concerned in building contracts to draw trade acceptances against each other for the purpose of financing the different steps in the process of building.

The Board finds it difficult, if not impossible, to answer any general hypothetical questions with reference to this subject because of the fact that the elements necessary to determine the eligibility of various trade acceptances depend largely not only upon the general nature of the business which they finance, but upon the technical terms of the contract covering the particular transaction out of which they grow. There does not seem to be any doubt that a trade acceptance drawn by a manufacturer or material man upon a builder is eligible for rediscount as a trade acceptance, for that comes clearly within the terms of the Board's definition of such an instrument. It is equally clear, however, that if the nature of the contract under which the building operations are being conducted is such that the contractor, for instance, does not get title either to the materials furnished or to the building as it is being erected, he cannot properly make a trade acceptance of a draft drawn upon him by the subcontractor or builder, because of the fact that he has not been the purchaser of goods sold within the meaning of the Board's regulations.

It is apparent that building contracts vary so greatly in different localities and are always so intricate in their nature that it is impossible to promulgate any general ruling as to the possibility of the use of the trade acceptance to finance structural work and other building operations in general. Each case would have to be determined upon the facts as ascertained in the light of the contract under which the operations are being conducted.

If the drawer of the draft has sold "goods" to the drawee, the drawee may properly accept, and the draft thus accepted would constitute a trade acceptance, if otherwise in conformity with the Board's regulations; but it should be noted that labor in itself is not considered "goods" within the meaning of these regulations. The Board has ruled, however, that a draft drawn to cover the purchase price of goods sold, plus the cost of installing those goods, may be eligible for acceptance as a trade acceptance. (See Federal Reserve *Bulletin* of April, 1918, page 310.) At this time, however, the Board is not inclined to extend the scope of its definition of the word "goods" to include labor alone.

It should be understood of course, that nothing in this ruling should be construed to imply that a note or bill of exchange, the proceeds of which have been used or are to be used for the payment of wages or for services rendered, is not eligible for rediscount. It is merely intended to indicate that in order to constitute a specified preferred class of eligible bills of exchange specially designated as trade acceptances, the transactions out of which the acceptance grows must be one involving the sale of "goods" within the meaning of the Board's regulations.

This ruling is issued with the understanding that trade acceptances should not be used so as to extend the usual and customary terms of credit.

CODE RULES FOR SIGNALING SYSTEMS TO BE REVISED.

Members of the National Fire Protection Association and others interested are notified that the regulations governing the wiring of signaling systems are under revision and if they have any ideas to offer should communicate them to Ralph Sweetland, chairman of the Committee on Signaling Systems, 141 Milk street, Boston, Mass. These regulations refer especially to Rule 85 of the National Electrical Code.

Contractor-Dealer

Timely Aids to Fan Sales — Mr. Casey Gives Valuable Merchandising Suggestions — Experience of Some Dealers

USEFUL IDEAS IN SELLING ELECTRIC FANS.

Timely Hints for the Dealer Derived from the Experience of the Hydro-Electric Power Commission of Ontario.

The electric fan is an article which can be used the year around for many services other than the services for which it was originally developed, and the public is gradually learning more and more to use the fan at all seasons. This fact has been emphasized in many issues of the ELECTRICAL REVIEW and we are glad to see it being taken up by other electrical papers. For instance, the *Bulletin* of the Hydro-Electric Power Commission of Ontario says, as an aid to uniform heat distribution in winter the electric fan is almost as valuable as it is to prevent discomfort from the heat in summer. It can be used for drying clothes, photographic plates, vegetables, etc.; for driving steam and odors from the kitchen, refrigerator, closets, etc.; for keeping the frost from show windows, and dozens of other services which make it an article of year-around utility.

From a sales angle, however, the fan is still a seasonable proposition, and can be sold to the best advantage during the one or two hot months of the year only. After the purchaser has obtained his fan, he will use it for many of the extra services for which it is suitable, but in 99 cases out of 100 the appeal which makes the sale and the only one which will do so is the hot-weather-comfort appeal, and, curiously enough, this appeal is effective only right at the time when the prospect is actually experiencing the discomfort of hot weather.

The heat of one day is forgotten the next, provided a cool breeze has sprung up to dissipate the heat, and when one hot day or week has ended in a cool wave, apparently no one ever expects to experience another. So sensitive are fan sales to weather conditions, in fact, that, other things being equal, the sales of fans from day to day will fluctuate in exact ratio to the fluctuations of temperature.

When warm weather is present, every possible means of placing the message of fan comfort before the public should be utilized to the limit. The sales helps furnished by the fan manufacturer should be employed so that every possible user of a fan will get the message in some form. Newspaper advertisements, movie slides, window displays, mailing folders, all available advertising helps should be held in readiness, so that they can be put to work on the first hot day.

These advertising helps should, of course, be supplemented by personal and telephone calls, where the prospects are best for sales. Lists of such prospects should be made up in advance of the fan weather, so they will be ready for use when the hot weather breaks and a hot spell starts in.

Lists should be made up of homes where there are small babies and invalids. These can be compiled from news items in the press and from birth records. Such prospects could be covered by telephone calls. A tactful reference to the value of a fan as an aid to convalescence or as a comfort to the little one, with an inquiry as to whether the prospect would like to have one sent for trial, will bring many trial requests at small expense, and once the fan gets into such homes on trial, the results it shows will usually make the sale.

Small offices, such as the doctor's, dentist's, lawyer's, architects and others, can also be solicited by telephone. A cheery reference to the heat and a request to permit a fan to be sent over to demonstrate how much better the work will go with its help, will usually result in a sale.

Hospitals are excellent prospects, as the fan is a real aid to quick convalescence during hot weather. When the hospital board cannot be influenced by direct salesmanship, often they can be sold through indirect methods. For example, a fan sold or loaned to one private patient in the hospital will make such a strong contrast between the room where the fan is used and others not so equipped, that doctors and nurses will be strongly impressed with the value of fans, and their remarks will help put the message across with the management and directors.

Wherever the fan can be shown in operation, it is always in itself the best possible fan salesman. A demonstration is better than the best verbal arguments of the best salesman. During hot weather the store should be equipped with fans in operation, so that no person can come into the store for any purpose without getting a demonstration of fan comfort. Price tags, counter signs and folders should be arranged about, so as to invite a direct inquiry from the caller before he leaves the store.

The passers-by on the street can be reached in a similar way by having a fan in operation just outside the window or door, so that it directs a breeze toward the sidewalk. A sign near the fan, such as, "If you enjoy this breeze, take it with you. Come inside for particulars," or something of this nature, should be used to clinch the sales message of the fan.

If sales policies will permit it, fans should be sent out on trial at every opportunity. However, in doing this it is very important that they be sent at the right time. On a cool day a fan sent out on trial is effort wasted. On a severely hot day, it nearly always means a sale, as mighty few people are willing to give the fan up when they are enjoying its use.

It is also well to emphasize the low current consumption of the fan by pointing out that it uses no more current than an ordinary incandescent lamp, and that it will not add a noticeable amount to the monthly current bill. Many people imagine, because a fan makes a great stir and commotion in the air, that it must use a lot of current. This impression should, of course, be corrected.

Better Merchandising—Its Methods and Advantages

Why Electrical Contractors Should Open Stores—Value of Service as an Advertisement—Advantages of Part-Payment Plans—Selling Hints

By THOMAS J. CASEY

Vice-President, Hurley Machine Co., Chicago.

ONE of the greatest problems confronting the electrical industry at the present time is the need for more and better retail stores conducted by wideawake ethical merchants with a reasonably good understanding of electricity and modern business practice. This lack of stores besides not offering any encouragement to the use of electrical appliances in the home, is so great that it makes it difficult rather than easy for the self-convinced customer to purchase them.

And this condition naturally suggests the question, "Why shouldn't electrical contractors conduct retail stores for the sale of electrical appliances in conjunction with their contracting business?" The writer has never heard one real satisfactory reason advanced in answer to this question nor does there appear to be any.

The profits from a properly conducted retail electrical establishment are surely as great, or greater, than those of electrical contracting and in addition are much more reliable and stable and are not subject to seasonable conditions. This is proven by the fact that many contractors who engaged in the retail business simply as a matter of convenience for their customers have since practically discontinued contracting. However, as the amount of detail supervision in connection with a store is small when compared with contracting both can usually be conducted without interference or overtaxing the owner's efforts.

One objection that is often raised is that the contractor is not a salesman. If this were true, how does he obtain his contracting business? Doesn't it require better salesmanship and the customer's confidence to a greater extent to secure a wiring contract which is more expensive than an electric appliance and which becomes a permanent part of the customer's home and cannot be exchanged or thrown out? And having thus obtained the customer's confidence by installing satisfactory wiring, is there any reason why he should not capitalize this confidence by selling the appliances to be used in connection with the wiring also? The time has passed when people had their homes wired for lighting only. On the contrary, lighting is becoming a secondary consideration to be enjoyed as a by-product to the many other conveniences and helps that electricity makes possible. The contractor is the logical man to furnish these appliances for he already has the customer's confidence and it is his duty to assist the customer in getting the greatest return on the wiring investment.

Thomas J. Casey.

Starting the Store.

In starting the store there are several features that should be carefully considered. The first and most important perhaps is the location. This, of course, is determined largely by local conditions but it should be convenient to the trade and situated so that it can be easily located. In choosing a store special attention should be given to the available show window space and its prominence as compared with those of the adjacent stores.

Next comes the selection of stock. Very often this is done in a half-hearted manner, only a few appliances being purchased at a time, these being of the smaller and cheaper grades. This seldom makes for success nowadays, for the public demands service and will trade only where they can get what they want when they want it. The dealer, therefore, should have a sufficient stock to supply the demand immediately and this should be of a good, dependable quality if he intends to continue in business.

The third feature of the store is its arrangement and attractiveness. The most important part of this is the window displays. The show window is the

ity. After apparently exerting every effort to sell merchandise, they find that the people will not buy electrical goods sufficiently to warrant their keeping in business. Upon investigating, however, it is found that in practically every instance the dealer himself is at fault and when another dealer opens a store in the town with the same or a similar line of merchandise he invariably meets with the success that the first could have achieved had he used the right methods.

When a dealer is confronted with this difficulty, therefore, he should first analyze his own methods and business rather than rebuke the community in which he lives and from which he derives his living. In far too many cases his own estimation of the community can be blamed for his difficulties, for, above all, a dealer to be successful must have faith in his community and try to be its foremost booster. Another recourse which the dealer has in such instances is to appeal to the manufacture or supply jobber who will often be able to solve the problem for him.

A Timely Newspaper Advertisement That Brought a Flood of Orders.

Advantages of Part-Payment Plans.

Another feature which should not be neglected in the conduct of a successful retailing business is the part-payment or installment plan. A great many merchants object to such methods, feeling that it lowers the standing of the store and places their business on a level with the cheap installment house. This contention is exaggerated for, although most inferior goods are on the installment plan, it does not necessarily follow that all goods sold by such methods are inferior. Nor will they reduce the standard of the establishment in the minds of its wealthier patrons because the installment idea has become part of our life nowadays and no matter what a man's financial position may be, he employs it to some extent at least, for example, in paying his rent, etc. Such methods have been employed for years by many of the most reputable concerns, notably in the sale of pianos and talking machines, where the great success that has been achieved is largely the result of the part-payment plan.

The reason for this feeling among the well-to-do class in particular is easily explained. The majority of men give their wives a fixed weekly or monthly allowance from which they are to pay all expenses of running the home, and it is a source of satisfaction to the wife to make this go as far as possible. To make a cash payment for an appliance from this allowance or to save for it before purchasing is a difficulty which the installment plan solves. In addition the part-payment plan makes possible the immediate purchase of goods from the amounts ordinarily carried when customers are seized with the impulse to buy. Such plans should be arranged on, quite easy payments, however, which means that the average monthly payment on articles selling for around $100 should not be more than $10.

The added expense of such plans should be borne by the customer in the form of a slight additional price. Dealers should not be timorous about making such charges for the customers expect to pay them and are skeptical of the value of the goods if they don't have to.

Another advantage of the part-payment plan is that it brings people into the store. Many of the large department stores spent great sums in advertising goods which they sell at little or no profit, simply to attract customers to their places of business, realizing that they will undoubtedly purchase other goods before leaving. When a dealer sells an appliance or device on the installment plan he makes it necessary for that customer to come into his store a certain number of times that he would not have done otherwise, which not only gives the dealer an opportunity to sell him other appliances but makes him more familiar with the dealer, his store, salespeople, and methods which encourages further patronage.

Sales Hints.

A common fault among electrical dealers is that while they earnestly endeavor to advertise and display their goods to the best advantage, they leave the goods to sell themselves in the store or employ poor methods of selling. This was demonstrated in a western city not long ago.

The dealer in this place was apparently exerting every effort to sell merchandise but with only fair success. His advertising was faultless, his store neat and attractive, he employed the most approved business methods, and a good force of salespeople, but still he did not improve. One of the devices he was not very successful with was the electric washing machine. These were prominently displayed in his store near the entrance, where everyone entering and leaving could not help but notice them. Upon investigation it was found that while a great many people paused to examine these machines, none of the salespeople ever paid attention to them. A salesman was therefore delegated to try to sell those customers who appeared interested but only a little better success was obtained.

Then the salesman's methods were studied. When a customer paused at the washing machine he would approach with the inquestion, "Are you interested?" Invariably the answer was "no" and the customer walked out. The question in itself suggested that answer and also gave the customer the impression that she was not to look unless she intended to purchase. The fallacy of such methods is apparent. The salesman was instructed to approach the prospects in this manner, "Madam, if you will stand here I'll show you how this machine operates." The customer would unconsciously stand as requested and become more and more interested as the demonstration proceeded. By such methods the dealer's sale of washing machines was increased from barely 15 a month to more than 75 and a similar increase was noticed throughout the store.

Another valuable method is to group appliances that naturally suggest each other by their uses. For example, if during a sale the electric toaster is especially featured, an electric percolator or hot plate or similar appliance should be prominently displayed with the toaster. Or if an iron is featured it should be displayed on top of a washing machine or near an ironer. In this way the salesman in explaining the feature merchandise has an opportunity to demonstrate the others. This often results in the purchase of both, if not at the same time at some later date.

Advantages of Carrying But One Line of Merchandise.

In the writer's opinion it is a mistake for any dealer to carry more than one line of merchandise. By doing so he not only tends to confuse his customers but he is prevented from using his most forceful methods on any of his lines.

For example: A customer enters a store carrying several competing lines of vacuum cleaners, all priced about the same, and in the customer's mind, one as good as another. The customer is confused as he cannot tell which is the best purchase, and the salesman hesitates to center his efforts on any one make for fear of conflicting or condemning some other make that the customer may have secretly decided upon before coming to the store. Furthermore, if the salesman endeavors to push one make too strongly the customer is very apt to think that the profits of that particular make are greater than any other and he therefore can only point out the faults of the various types. In any event, the customer is impressed with the fact that some vacuum cleaners have faults and shortcomings and these probably exist in all of them and decides not to buy.

If on the contrary, the customer goes to a store handling only one line, the salesman can point out the good points of that particular make rather than its poor features without fear of conflicting with any other make. He can explain that this particular type is absolutely the best on the market, in his opinion, otherwise he would not carry it. He can concentrate on that machine, show its operation and advantages and in all probability will make the sale.

However, the dealer should select a line that he can depend on to meet his claims for it, for such a sale carries with it the dealer's recommendation, if not his guarantee, and he is held responsible for its performance. If the machine satisfies, the dealer can feel certain of that customer's future patronage; if not, his store has lost caste as well as the device.

WHAT CAUSES BLACK SPOTS IN POWER WASHING MACHINES.

Very often women using power washing machines complain of black spots that appear on the clothes that have been washed. These spots are very difficult to remove and usually are found only on the clothes that are washed last, although they may also be found all through the wash.

Many dealers, when customers complain of these spots, blame the soap that is used, but this is usually wrong. The trouble is that the washer is filled too full of water which works into the bearings and loosens the lubricating oil there, causing it to run into the tub, and this causes the spots. The reason the spots are noticed more often near the end of the wash is that the water in the tub, having cooled during the wash, is heated when hot water is poured in without any of the cold water being drawn off.

MAKING CUSTOMERS APPRECIATE VALUE OF DEALER'S SERVICE.

Novel Plan Adopted by Contractor-Dealer to Compare His Service with That of Mail-Order Firm.

It is often a difficult matter to make customers appreciate the value of the service rendered by the local contractor-dealer as compared with the large mail-order house. However, one dealer in a small western city seems to have found a very effective means of keeping trade from going to the mail-order firms, according to a recent account in *Contact,* the Westinghouse Electric & Manufacturing Co.'s publication for its dealers.

This contractor-dealer purchased one of the irons sold by the mail-order firm which he displayed, in the original package, on the counter beside his regular stock of irons. When a prospective purchaser would mention the mail-order iron and its price, he would offer to sell her this iron at the same price as the mail-order house charged, but would insist that the customer purchase it in the package, without opening it. the same as he would purchase it by mail. In this way the value of the service rendered by the dealer was plainly shown, and although he has had the mail order iron for some time and has brought forth this argument very often, it still remains unpurchased and has proved a very profitable investment for the dealer.

HOT-WEATHER APPLIANCE SALE BY MAIL.

A hot-weather drive on toasters and household irons is being conducted by the Public Service Co. of Northern Illinois in all of the communities it serves. A choice of two irons and two toasters is given the prospect and the appliances are being sent out on the basis of a 10 days' free trial. If retained the price is paid in monthly installments.

An attractive mailing card printed in two colors and giving illustrations and full details of the appliances has been sent to every customer. A self-addressed return post card is provided for the customer, the idea being to conduct the campaign entirely by mail.

LAMP SALE EXPERIENCES IN NEW YORK CITY.

It has been found in New York City that under proper conditions more incandescent lamps can be sold by the central stations, jobbers, dealers and manufacturers than the central stations were able to dispose of under their renewal or combined sale and renewal policies.

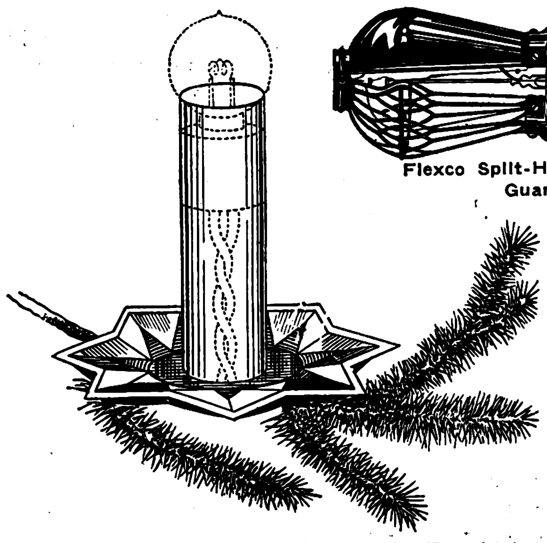
New Appliances

Candle-Sticks for Tree Lamps—Tungar Outfit for Private Garages — Portable Lamp with Reflector — Quad Heater

Van Christmas Tree Candle-stick.

It is still quite a long time to next Christmas but wise dealers prepare during the summer for the sale of winter goods. The large demands for Christmas tree lighting sets last year are likely to be very greatly exceeded this year since we are now quite definitely out of the war and decided prosperity is gradually looming ahead. It is therefore the part of prudence to think of the demands of the next Christmas season and prepare for the same in ample time

Many purchasers of electric tree lighting outfits have expressed a desire to have the electric lights, if possible, resemble the old candle for sentimental reasons only. This has been made possible by the development of a candle-



Christmas Tree Candle-stick for Electric Tree-Lighting Sets.

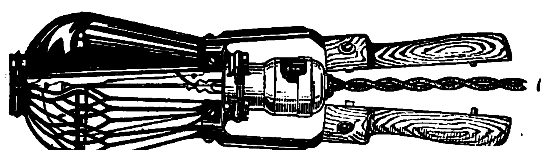
stick especially suited to the electric lights usually provided for tree lighting. It consists of a white tube mounted on an ornamental candle tray or reflector on the bottom of which is a spring clip for fastening the outfit to the limb of the tree. These trays are made in four colors, red, blue, green and gold. The candle-sticks are sold in sets of 8, there being two of each of the four colors in each set.

These candle-sticks are easily installed. The lighting outfit is first strung on the tree, then the lamps are unscrewed from their sockets (one at a time) and the sockets pushed up through the tube of the candle-stick to just come flush with the top; the lamp is now screwed back into the socket and the candle-stick complete with lamp is finally fastened to the limb of the tree by the spring clip at the bottom.

The effect is very pleasing, reproducing the old-fashioned candle lighting effect without its fire hazard and inconvenience. Many of these candle sets were used last Christmas and created very favorable comment as well as a demand for more of them. They are made by C. B. Van Antwerp & Co., 26 West Lake street, Chicago, Ill.

Portable Inspection and Trouble Lamp with Reflector and Guard.

One of the highly efficient conveniences for everyday use in factories, mills, machine shops, foundries, garages, power plants or shops of any kind, is the new Flexco split-handle reflector portable lamp guard, a product of the Flexible Steel Lacing Co., Chicago, Ill.



Flexco Split-Handle Portable Lamp with Guard and Reflector.

In every plant there are innumerable places which make the need of an efficient portable electric light imperative. In engine pits, under machines and automobiles, in warehouse pits and other places not lighted under ordinary circumstances the Flexco split-handle portable carries the light safely and conveniently. This new product eliminates fire hazard because it does away with the careless use of torches and lighted matches in out-of-the-way places where a light is often needed.

The three advantages of this ingenious contrivance—(1) taking the light where wanted because it is portable, (2) protecting the bulb from breakage, (3) reflecting the light away from the eyes of the user and toward the work to be illuminated—make it a very valuable convenience for every shop and plant where light is needed in many unusual places.

The guard is made of expanded steel, well coated with tin. The split handle is adjusted by means of screws, and it hinges with the guard as a base. It clamps over the socket of an extension or drop cord without rewiring. The cord runs through the grooves in the split handle.

This contrivance is another of the popular products of the Flexible Steel Lacing Co., manufacturer of Alligator steel belt lacing, Flexco and Flexco-Lok lamp guards and "High Duty" fasteners for conveyor and elevator belts.

New Private-Garage Type of Tungar Rectifier.

A new size Tungar battery-charging rectifier has been developed by the General Electric Co., Schenectady, N. Y., for charging storage batteries from an alternating-current circuit.

It has been designed especially to meet the requirements of the automobile owner who desires to charge his starting and lighting battery at home, or in a private garage. Special effort was made to make this device as simple, compact and efficient as possible.

This Tungar outfit will charge:

1 three-cell battery at 5 amperes, 2 three-cell batteries at 3 amperes, 3 three-cell batteries at 1½ amperes, 1 six-cell battery at 3 amperes.

It operates on a standard 115-volt, 60-cycle, alternating-current lighting circuit.

The essential parts consist of a Tungar bulb for rectifying the current, and a transformer for reducing the voltage. Both are contained in a sheet-metal case of attractive design.

This Tungar rectifier operates on exactly the same principle as the other rectifiers of this type.

The operation is very simple. Set the Tungar on the floor, on the running board of the car, or hang it on the wall. Connect the direct-current leads to the battery with the spring clips which are provided and screw the attaching plug into a convenient lamp socket. The Tungar starts charging immediately. It has been approved by Underwriters' Laboratories, and can be safely operated over night without attention.

New Radiant Air Heater of Quad Type.

American Electrical Heater Co., Detroit, Mich., has added to its line of air heaters a new design known as the "American Beauty Quad." It is an amplification of its twin radiant heater but has four units, two on each side of the standard and superposed over each other. Each unit is rated at 330 watts, making the total 1320 totals. Each pair can be controlled separately. Each unit has its own reflector that can be adjusted within a certain angle.

Since each of the reflectors is of circular outline and approximately parabolic shape, it makes a very efficient means of directing the heat to a considerable distance. Each reflector being separately adjustable, the entire combination affords a convenient means for either projecting the heat over an area or concentrating it at a desired point.

Trade Activities

Holtzer-Cabot Electric Holds Sales Convention—Francis Vaughn Manufacturing Organizes — Special Literature

Electric Furnace Construction Co., Philadelphia, Pa., has received an order for an electric furnace for the manufacture of ferro-alloys for Spain, by the Sociedad Espanola de Construccion Naval, the advisory committee of which consists of the firms of Sir W. G. Armstrong Whitworth & Co., Vickers, Ltd., and John Brown & Co. It is said that this is the first furnace of its kind to be erected in Spain for converting their own natural ores into ferro-alloys.

The Cutler-Hammer Manufacturing Co., Milwaukee, Wis., in the Independence Day issue of the C-H Messenger, the house organ of the company, devotes numerous pages to photographs and names of C-H men who served their country during the recent world war. The list includes nearly 300 names and of this number eight men made the supreme sacrifice. This number of the C-H Messenger is gotten up in an attractive manner and is carried out in the national colors.

The Electric Hoist Manufacturers' Association, New York City, has issued a very interesting and instructive booklet entitled "Facts for Operators of Electric Hoists," discussing the care and use of electric hoists. This was prepared by the engineering committee and is available to all interested by applying to W. C. Briggs, secretary of the association, 30 Church street, New York City. A new booklet on track, supports, current conductors, etc., will be issued soon by this organization.

Francis Vaughn Manufacturing Co., Milwaukee, Wis., has been incorporated with a capital stock of $50,000 to manufacture electrical and other devices, instruments and appliances. Francis Vaughn, 271 31st street, head of the new enterprise, is senior partner in the firm of Vaughn & Meyer, consulting engineers of Milwaukee and Wausau, Wis., and Minneapolis. He is also business director of the Milwaukee School of Engineering and a leader in electrical affairs in Milwaukee as well as throughout Wisconsin.

R. A. Nuttall Co., Tractor Department, Pittsburgh, Pa., is distributing a booklet devoted to the subject of "pedigreed" gears and serves to better acquaint tractor owners and prospective owners of the need of scientifically designed and constructed gears and will prove helpful in making the selection of a tractor. It contains considerable information on the subject, explaining clearly the difficult work that tractor gears must perform and points out the causes of gear troubles and inefficiency, how inefficient gears waste power, etc. The booklet covers 16 pages and is replete with illustrations.

Duparquet, Huot & Moneuse Co., 108-114 West 22nd street, New York, manufacturer of French ranges, kitchen equipment, utensils and furnishings, has ready for distribution to the trade a new 88-page catalog dealing exclusively with heavy-duty electric cooking equipment for the hotel, restaurant, cafe, factory, club, hospital, steamship, yacht, mansion, sanitarium or kindred institutions.

Moran & Hastings Manufacturing Co., 16-18 West Washington street, Chicago, is sending out a circular on "Raymo" adjustable fixtures designed especially for the office, storage room or factory. Over 1700 of these fixtures have been installed and are meeting the rapidly increasing demand for efficient lighting units. The fixture, heat deflector and fitter are finished in roman gold; the husks, arms and studs are finished in white enamel, presenting a very attractive appearance.

Automatic Electrical Devices Co., Cincinnati, Ohio, has issued Bulletin 615 dealing with the Ogden automatic metallic drum controller (Type NS) for use on storage battery industrial trucks, tractors and locomotives. This type of controller, which was described in our issue of June 28, was designed to meet Government specifications for use in munition plants and the like. It was produced in enormous quantities for use by the War Department. Now that these orders have ceased the company is in a position to furnish these controllers for general commercial use. The bulletin describes the details of construction and the numerous advantages of this type of controller, which has been built especially to withstand the severe service to which this type of equipment is subjected.

Sales Convention and Outing of the Holtzer-Cabot Electric Co. — The sales convention of the Holtzer-Cabot Electric Co. was held recently at the home office and factory in Boston. E. R. Harding, vice-president, with four of his Chicago executives, were present, besides the branch managers and other salesmen from various cities. Several important items were discussed each day, including many new and improved devices which were demonstrated by the engineering staff. These meetings have been productive of so much good that it is planned to have them four or five times a year. As the various territories present different aspects of merchandising, the free interchange of opinions is of great assistance to all the selling staff.

The convention was closed by a week-end stay at South Yarmouth on Cape Cod, about 80 miles from Boston. Personally owned automobiles carried a party of 21 both ways along the ideal Massachusetts roads. The opposing teams in all games and contests were captured respectively by E. R. Harding, vice-president, and T. W. Ness, sales manager. All the honors, however, seemed to go to the Westerners. Mr. Harding's team carried off the prize for the bowling tournament by a very close margin. Mr. Harding also took first prize in catching the largest fish. The hard-fought baseball game also went to the Chicago men, although the fans from Washington and New York made a very good showing. The courtesy of Messrs. Schirmer, Sr. and Jr., was extended to the whole party; their two beautiful country homes on the shore were given over entirely for the accommodation and entertainment of the visitors, a courtesy that was much appreciated.

Signal Systems Division of the Holtzer-Cabot Electric Co., Boston.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Portland, Me.—Considerable electrical and mechanical equipment will be required for the proposed plant to be erected near Portland, by the American Can Co., 120 Broadway, New York, N. Y. Bids for the new plant are now being asked. The structure, with equipment, is estimated to cost about $300,000.

Lynn, Mass.—The Board of Water Commissioners has arranged for the erection of a new electric pumping plant at Hawkes Pond, near Saugus, Mass., to cost about $15,000.

New Bedford, Mass.—Considerable electrical equipment, including motors, industrial control apparatus, etc., will be installed in the new mill to be erected by the Fairhaven Mills. The structure will be two-story, located on Coggeshall street, and is estimated to cost $100,000.

Putnam, Conn.—The Nightingale-Morse Mills, Putnam, Conn., manufacturer of textiles, has awarded a building contract to the H. Wales Lines Co., 134 State street, Meriden, Conn., for the construction of a new hydroelectric power plant to cost about $80,000. The structure will be used for works operation.

Westerly, R. I.—A power plant for works operation will be installed by the Rhode Island Silk Co., in connection with the construction of a new mill, estimated to cost about $125,000. The power plant will be one-story, about 40x40 ft.

Albany, N. Y.—The state authorities are having plans prepared by State Architect Lewis F. Pilcher for power and boiler plant improvements at a number of state institutions. The work will include a new boiler plant at the Potsdam Normal School, Potsdam, to cost about $100,000; new boilers, stokers and ash handling equipment at the Central Islip State Hosptal, Central Islip, to increase the capacity of the present plant at this location, with cost estimated at $135,000; new generators at the Brooklyn State Hospital, to increase the present capacity, to cost about $15,000; new boilers and auxiliary equipment at the Oneonta Normal School, Oneonta, to cost $10 000; and a new pumping plant at Sing Sing Prison, Ossining.

Brooklyn, N. Y.—Brooklyn Rapid Transit Co., 85 Clinton street, has acquired property at the corner of Kent avenue and South Sixth street as a site for the erection of a new electric power station. The property was held at about $350,000.

Brooklyn, N. Y.—Mergenthaler Linotype Co., 24 Ryerson street, has completed plans for extensions and improvements in its boiler plant to increase the present capacity.

Brooklyn, N. Y.—Long Island Lighting Co. has been granted permission by the Public Service Commission, Second District, to issue bonds for $180,000 and stock for $80,000, the proceeds to be used for extensions and improvements in its plant and distributing system.

Buffalo, N. Y.—Robinson-Cataract Electric Co., 151 West Mohawk street, has awarded a contract to the Turner Construction Co., Prudential building, for the erection of its proposed six-story works building at 128-130 South Elmwood avenue. The structure will be 45x115 ft., and is estimated to cost $100,000.

Glens Falls, N. Y.—Arrow Grip Manufacturing Co. is planning a new two-story plant to cost $150,000 and is to be equipped for the manufacture of patented grips to secure automobile chains in place.

Middleport, N. Y.—Western New York Utilities Co., Inc., is extending its power line to Barker, a distance of 13 miles.

New York, N. Y.—A new indirect electric lighting system and other electrical improvements will be made by the South & Central American Commercial Co., Inc., in the portion of the building at 119-121 Pearl street, recently leased for a number of years at a rental of about $100,000 for a new establishment. The company will occupy four floors at the new location.

New York, N. Y.—New York Edison Co., 130 East 15th street, has filed plans for the erection of a two-story building, 25x75 ft., at Hester and Norfolk streets, to cost about $35,000.

New York, N. Y.—Public Service Commissioner John H. Delaney has made application to the Board of Estimate for an appropriation of $520.000 to provide for the expense of the Public Service Commission for the new quarter to begin July 1. This is an increase of about $43,000 over the amount granted for similar purposes for the quarter just ended.

New York, N. Y.—The Up-State Public Service Commission has passed an order authorizing the Long Island Lighting Co. to issue $180,000 5% 25-year first mortgage bonds, and $80,000 in common stock. The proceeds of the securities to be used exclusively for construction and betterments. Address E. J. Phillips, 50 Church street.

New York, N. Y.—An electric traveling crane, motors and other electrical equipment will be installed in the new works of Julius Blum & Co., manufacturere of steel tubing, shafting, etc., 532-40 West 22nd street. The company is now located at 510-12 West 24th street, and has secured a long lease on the five-story building at the new location. Alterations and improvements will be made before removal.

Ossining, N. Y.—The Catholic Foreign Mission Society of America will build a new power plant at its local institution. A mechanical laundry plant will also be installed.

Pierrepont Manor, N. Y.—Northern New York Milk Co. will install boilers, electric power motors and an ammonia ice plant in connection with the milk station, evaporating plant and milk shipping station, which it plans to build. Estimated cost, $200,000. Address F. P. Redfield, Adams.

Atlantic City, N. J.—Considerable electrical equipment will be required for the new hotel to be erected by the Ritz-Carlton Co. at Illinois avenue and the Boardwalk, on the site adjoining the Hotel Traymore. The structure will be 12-story, with about 800 sleeping rooms and baths, and is estimated to cost $3,750,000, exclusive of site, which is valued at about $1,000,000. The electrical work will include boiler and refrigerating equipment, mechanical laundry apparatus, fixtures, ornamental lights, etc. The new hotel will be erected by Cramp & Co., Denckla building, Philadelphia, Pa., building contractors.

Long Branch, N. J.—The War Department, Washington, is arranging for the purchase of the present site of Camp Alfred Vail at Little Silver, near Long Branch. The property includes about 450 acres, and the consideration is estimated at $125,000. The department has a number of buildings at this location at the present time, and proposes to use the site for an extensive radio station for research and experimental work.

Newark, N. J.—Electrical service at the proposed Essex Mountain Sanatorium, now in course of erection by the Board of Freeholders, is estimated to cost about $30,000, including the installation of apparatus, fixtures, etc.

Newark, N. J.—In connection with a two-story and basement addition to its plant for increased capacity, the Seton Leather Co., 62 Verona avenue, will build a new one-story boiler plant, about 40x40 ft. The entire improvement is estimated to cost about $40,000.

Phillipsburg, N. J.—The City Council in conjunction with members of the local Merchants' Committee, is considering plans for extensions and improvements in the street lighting system. It is proposed to install new standards along South Main street, from Jersey to Jefferson streets, in the business section, and to make similar installations in other sections.

Pompton Lakes, N. J.—The new municipal electric power plant has now been placed in operation under regular service. The borough for some time past has been purchasing electric energy from E. I. du Pont de Nemours & Co., the service being rendered from the electric power plant at its local power works.

Succasunna, N. J.—The Township Committee, Roxbury Township, has awarded contracts for lighting the streets of the district to the New Jersey Power & Light Co., Dover; and the Mills Brook Electric Light Co., Netcong. The companies will commence the immediate construction of new pole lines for the installation; about 100 lights will be furnished by the New Jersey company and 55 lights by the Mills Brook organization. A terminal for each utility company will be located at Landing. The roads to be lighted include the main highways from Kenvil to Succasunna, to Ledgewood and to the Lower Flanders Road. The contract calls for the completion of the work and the inauguration of service early in August.

Trenton, N. J.—Electric pumping equipment and other electrical apparatus will be installed in the proposed sewerage disposal plant now being planned by the City Commission. The plant will have a disposal capacity of about 25,000,000 gal. of sewerage every 24 hours. The first unit is estimated to cost about $500,000.

West Orange, N. J.—Considerable electrical and mechanical equipment, including electric motors, lighting fixtures, switch controls, etc., will be required for the new junior high school to be erected by the Board of Education. The structure will be three-story and basement, and is estimated to cost $290,000. Guilbert & Betelle, 665 Broad street, Newark, are architects.

Altoona, Pa.—An electric power plant, ice-manufacturing plant, mechanical laundry and other departments for general service will be erected by the Le Roy Hotel Co., in connection with the complete rebuilding and remodeling of its hostelry. Considerable electrical apparatus, including fixtures, ornamental lights, etc., will also be required for the structure. The new hotel is estimated to cost $600,000. Walter Frieling, Hutchinson building, Altoona, is architect.

Easton, Pa.—To increase the capacity of its local plant, the Pennsylvania Utilities Co. has perfected plans for the installation of three new boilers at its local power plant. One of the units will be 1000 hp. and the other two, each 650 hp. They will be provided with auxiliary operating equipment, including Westinghouse type underfeed stokers.

Homestead, Pa.—Homestead Gas & Electric Co. has received a contract for electrical work and equipment in the new produce building now in course of erection on Seventh avenue, by G. T. Debolt.

Meadville, Pa.—Fire recently destroyed the local car barns of the Northwestern Pennsylvania Railway Company, including electrical and mechanical equipment, with loss estimated at $64,000. It is understood that the structure will be rebuilt.

DATES AHEAD.

National Association of Electrical Contractors and Dealers. Annual convention, Milwaukee, Wis., July 15, 16 and 17. General manager, William H. Morton, 110 West 40th street, New York City.

Ohio Electric Light Association. Annual meeting, Cedar Point, Ohio, July 15-18. Headquarters, Breakers Hotel. Secretary, D. L. Gaskill, Greenville, Ohio.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 19-21. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26, 1919. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston block, Seattle.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Philadelphia, Pa. — Hess-Bright Manufacturing Co. is having plans drawn for a two-story addition, 40x100 ft.

Philadelphia, Pa.—The Bureau of Yards and Docks, Navy Department, is planning for extensive additions to the different buildings at the League Island Navy Yard. The Senate has voted to increase the appropriation for the work from $1,500,000 to $3,800 000, making available sufficient funds to carry out the proposed plans. The work will include a new central power plant with electric distributing system, estimated to cost $500,000; a new machine shop for light manufacturing to cost $400,000; new pattern shop, $400,000, and machinery and equipment, including electrically operated apparatus, with improved facilities for handling guns, armor, structural steel, turrets and other items used in connection with shipbuilding and ship fixture work. In the industrial buildings to be erected a large quantity of electrically operated machinery with individual motor drive will be installed. The Bureau has also arranged for the completion of the drydock now in course of erection at a total cost of $4,700,000. Electric cranes, hoisting, handling and conveying machinery will be used in connection with the operation of this dock.

Pittsburgh, Pa.—In connection with its welfare operations for employes, the Westinghouse Electric & Manufacturing Co., East Pittsburgh, is building a new two-story and basement lunch room, 100x240 feet, to cost about $40,000.

Pittsburgh, Pa.—Duquesne Light Co. will build a new condenser plant and switching station at Carnegie, near Woodville, Pa., to cost about $10,000.

Reading, Pa.—Metropolitan Edison Co. has arranged for the remodeling of its former power station at Lebanon into a modern substation for service in this district. The station will be tied in with the new No. 2 high tension line now in course of construction between the main power plant and Lebanon, extending from Reading. This line will provide considerably increased capacity throughout this district.

York Haven, Pa.—York Haven Water & Power Co. is preparing plans for a one-story machine shop, 45x65 ft., to cost $25,000.

Wilmington, Del. — Hall Radio Corp., Chicago, Ill., a Delaware corporation, has filed notice of change of name to the Hall Research Corp.

Wilmington, Del.—The King Street Improvement Association, recently organized for the betterment of this business thoroughfare, is planinng for the installation of new electric light standards on the street. The association is negotiating with the Board of Street and Sewer Directors for the improvement. Charles Topkis is president of the association.

Baltimore, Md.—Eastern Rolling Mill Co. has awarded a contract to the General Electric Co., New York, N. Y., for electrical equipment for its proposed works near the Bayview Asylum, Eastern avenue road. Contract for furnaces has been given to George J. Hagan & Co., Pittsburgh. The present plant is estimated to cost about $1,000,000 and will be devoted to the production of steel plates for automobile body manufacture, fenders, etc. It is said that later extensions, now contemplated, with machinery and equipment, will cost about $500,000. J. M. Jones is president.

Clearspring, Md.—Local citizens are organizing a company to construct and operate a distributing system for furnishing electric light and power throughout this section. It is proposed to render service at a cost of about 10 cents per kw-hr. Negotiations are under way with the Hagerstown & Frederick Railway Co. to furnish power at high voltage from its hydroelectric power plant on the Potomac River at Dam No. 5. A local substation will be erected to cut down the high-tension electric energy for commercial service.

Indian Head, Md.—The Bureau of Yards and Docks, Navy Department, Washington, has under advisement the remodeling and extension of the power plant and will receive bids for electrical machinery.

NORTH CENTRAL STATES.

Lebanon, Ohio.—An election will be held to vote on the question of issuing $120,000 electric light bonds. A complete new plant is necessary. Address village clerk.

Mansfield, Ohio.—Plans are being

prepared in the New York office of Henry L. Doherty & Co. for the erection of a new 10,000-kw. turbine at the company's central power station at Melco, 11 miles southeast of Mansfield, which when completed will duplicate the present plant and double the capacity. The new improvement will cost $350,000 and work will begin in 30 days.

Anderson, Ind.—Remy Electric division of the General Motors Corp. has adopted a new working schedule. A 48-hour week will be adopted and the employes will receive the same pay as they now receive for fifty hours. The men will work in two shifts, "A" employes working from 6:45 a. m. to 2:45 p. m. and "B" employes working from 3 p. m. to 11 p. m. About 3100 employes are affected by the new working hour schedule.

Indianapolis, Ind.—The merger of the Indianapolis Street Railway Co. with the Indianapolis Traction & Terminal Co. has been approved by the Indiana secretary of state and the charter has been issued. The former company has been operated by the Indianapolis Traction & Terminal Co. under a leasehold for a number of years. The capital stock of the new company will be $7,500,000. Directors include Henry Jameson, Charles S. Becker, Walter J. Ball, W. T. Durbin, R. K. Willman, H. C. Thomson, J. A. McGowan, John J. Appel and Robert I. Todd.

Kendallville, Ind.—Both Kendallville and La Grange are considering the sale of light and power to South Milford, Ind.

Chicago, Ill.—Cole Storage Battery Co. has acquired a building at 2435-39 Indiana avenue for the establishment of a new plant. The structure will be remodeled to accommodate the new works at a cost of $10,000.

East St. Louis, Ill.—Fire partially wrecked the plant of the local electric light and power company, causing a complete suspension of business and industrial activity in the city, as well as in Belleville, Alton, Edwardsville and other nearby cities. Repairs were rapidly made and service resumed. The fire was caused by oil on a switchboard becoming ignited and starting a blaze.

Peoria, Ill.—Davenport, Springfield & Southern Railway Co. is the name of the new transportation company that is being organized for the purpose of building an electric railroad, connecting the various towns between Davenport, Springfield and Metropolis. H. R. Campbell is chief engineer.

Vienna, Ill.—The council is planning to install an up-to-date power plant. Address city clerk.

Burlington, Iowa.—A special election is to be held to decide on construction and maintaining municipal light distributing system. Cost, $30,000. Address city clerk, E. P. Weinstein.

Davenport, Iowa. — White Lily Washing Machine Co. is building an addition to its plant to consist of two units. The extensions will cost about $165,000.

New Hampton, Iowa.—Northeast Iowa Power Co. received permission to construct a seven-mile electric light transmission line south from Fredericksburg. All farmers on the line voted to install the line.

Oelwein, Iowa.—Albert E. Green, Detroit, Mich., through his attorney, L. G. Hard, Dubuque, Iowa, has purchased the plant of the Oelwein Gas & Power Co. for $25,000. The property was sold by Lee McNeeley, clerk of the United States Court, who had been appointed special master by Judge Henry Reed. The Oelwein Gas & Power Co. has been involved in litigation for several months, the plant having been closed for failure to pay off its bonds. Mr. Green held the bonds and was successful in securing it. He expects to dispose of the plant.

Caruthersville, Mo.—Plans are being prepared by Black & Veatch, engineers, for the complete reconstruction and extension of the water and electric light systems.

Kansas City, Mo.—Black Steel & Wire Co. has completed plans for the erection of a new steel plant at its wire rope mill. This plant will consist of two furnaces for making steel ingots, together with electrically driven rolling mills and attendant machinery for the manufacture of steel ingots and rolling into wire road bars and shapes. The plant will have a capacity of 100 tons a day. W. E. Moore & Co., engineers.

Norborne, Mo.—Water, Light & Transit Co. has purchased the Norborne fuel, light and ice plant and is planning to furnish the Norborne lighting system with power by a transmission line from Carrollton.

Sikeston, Mo.—Election to vote $90,000 in bonds for proposed municipal light plant was defeated.

Springfield, Mo.—Springfield Gas & Electric Co. will construct an electric power plant to cost about $100,000.

St. Joseph, Mo.—J. W. Squires, Kansas City, Mo., has been commissioned to draw the plans and specifications for the improvements and extensions to the municipal light plant. He will begin at once with the preliminaries. A contract will be drawn allowing him 5% of the outlay for his services, which will amount to $25,000. Actual work will be begun this fall and the work will take between a year and 15 months.

Green Bay, Wis.—The city contemplates an ornamental lighting system on streets. Clarence A. Gross is on the committee.

Duluth, Minn.—The council adopted Commissioner P. G. Phillips' resolution for a better lighting system. The Duluth Edison Electric Co. will replace arc lights with new units, and will install eight lights to the block.

Minneapolis, Minn.—Sales Department of the Minneapolis General Electric Co. during the week ended June 20 secured 320 new electric light and power customers with 188 kw. of lighting and 265 hp. in motors, which includes contract for 150 hp. additional with the Washed Sand & Gravel Co. and 50 hp. with the Phoenix building displacing a steam plant operating the elevators. New business connected to the company's lines shows an increase of 106 customers with 94 kw. of lighting and 46 hp. in motors. A gain of 19% is shown in electric energy output over the corresponding week last year.

Tyler, Minn.—The village council is considering the purchase of additional equipment for municipal electric light plant.

Chanute, Kans.—An election will be held soon to vote $65,000 bonds for extensions and improvements in the electric lighting system. C. G. Wood, city clerk.

Hiawatha, Kans.—New pumps and other improvements are planned for the water system. Estimated cost, $25,000.

Hudson, Kans.—The city will vote on the question of issuing $15,000 in bonds for building a transmission line. E. R. Arnold, city clerk.

Kansas City, Kans.—The council is planning to expend $50,000 in improving city light plant. Howard R. Payne, city clerk.

Sharon Springs, Kans.—Engineers Black & Veatch, 507 Interstate building, Kansas City, Kans., are preparing plans for an electric light plant. Harry H. Wheeler, city clerk.

Springhill, Kans.—The electric light plant built five years ago has been closed and current will be furnished from Olathe, a distance of 10 miles from Springhill.

St. John, Kans.—The city is having plans prepared for building and extending the waterworks and electric light plant, for which $50,000 have been voted. Burns & McDonald, Interstate building, Kansas City, Mo., engineers.

Wichita, Kans.—The city permit has been granted for another unit for the Kansas Gas & Electric Co. plant to cost $275,000.

Minden, Neb.—Election to vote $35,000 bonds for lighting plant will be called in the near future.

Phillips, Neb.—Bonds have been voted for the erection of an electric transmission system by Grand Island Power Co. Address village clerk.

Pierre, S. D.—C. V. Seastone of Mead & Seastone, engineers, employed by the Hydroelectric Commission to make a preliminary survey of the Missouri river, has been here for the past ten days and has had a force of his men at work. The engineers will go over the entire river, and by a system of elimination determine the site which complies with the statutory requirements for the place where most power can be developed for the least money and where the current generated can be transmitted to every part of the state.

Watertown, S. D.—Engineer Lewis C. Larson, 18 Hendon avenue, St. Paul, is preparing plans for an electric light and power plant at an estimated cost of $175,000. Brown Mathier, city auditor.

SOUTH CENTRAL STATES.

Springfield, Ky.—Springfield Water & Electric Co. plans to change the plant to alternating current system and install panel switchboard, alternators, engines, etc. H. W. Mayfield, engineer, 298 W. Oak street, Ludlow, Ky.

Fort Smith, Ark.—Commonwealth Public Service Corp. will erect in the near future a large central power station in Johnson county near Clarksville. The plant will cost $200,000. Steam turbine engines will be used to generate the power.

Okemah, Okla.—Election to vote $23,000 bonds for waterworks improvements and $50,000 for electric light improvements, carried.

Tulsa, Okla.—According to Fred W. Insull, president of the Public Service Co. of Oklahoma, a new central power station will be erected for the purpose of generating and distributing electrical energy throughout the territory tributary to and within a radius of 50 miles of Tulsa. The station will be one of the steam turbine type and built to burn either coal or oil, the first of the units to consist of 8000 kw.

Dallas, Tex.—A chain of electric flour mills with a capacity each of 50 barrels daily is the plan of the Mutual Milling Co. recently organized here with a capital stock of $100,000. The concern has taken over a mill at Frisco, has built a new one at Grapevine and has had one in operation here for six months. It purposes to erect several more in Dallas and nearby towns. R. S. Fisher, president.

Dallas, Tex.—Dallas Power & Light Co. will build a substation here. The company has been granted permission by the city commission to construct a high-tension power transmission line in the proposed substation.

Luling, Tex.—The board of commissioners has been petitioned to call an election to vote on issuing $75,000 bonds, the proceeds to be used in constructing a municipal electric light plant and waterworks system here.

Sherman, Tex.—Plans have been submitted to the city commission for the erection of a power and light plant which will cost $650,000.

Waco, Tex.—O. A. Ryfle of Houston is promoting the organization of the Waco-Temple Interurban Railway Co. for the purpose of constructing an interurban electric railway between Waco and Temple, about 125 miles via the route that is proposed. Other men interested with Mr. Ryfle in the project are J. F. Wright, S. J. McGlasson, E. G. Van Zand and J. L. Davidson, all of Waco.

WESTERN STATES.

Grover, Colo.—A $34,000 bond issue has been voted for waterworks, etc.

Toledo, Ore.—The Fisher-Storey sawmill recently destroyed by fire is to be motor driven, power being supplied from a power plant built as a part of the mill.

Manti, Utah.—An election will be held to vote on the question of issuing $25,000 electric light and power bonds. Address city clerk.

Seattle, Wash.—Seattle has appropriated $1,000,000 for improvements and betterments in the street railway department and to enlarge the Cedar river power plant. The appropriations were for $500,000 for the railway system and $430,000 for the lighting plant.

California City, Cal.—The Bureau of Yards and Docks, Navy Department, has authorized the construction of an electric power plant at the naval coaling station to cost about $20,000. Officials at the Mare Island navy yard, Vallejo, will be in charge.

NEW PUBLICATIONS

Electrical Characteristics and Testing of Dry Cells.—The Bureau of Standards, Department of Commerce, has issued Circular No. 79 entitled "Electrical Characteristics and Testing of Dry Cells." This publication covers 44 pages and is divided into five sections. The first section is devoted to a brief discussion of the development of the dry cells and the succeeding chapters deal with the theory and construction of the dry cell; sizes and kinds of dry cells; electrical characteristics of dry cells; and testing dry cells. An appendix giving specifications for dry cells is included.

The Ultra-Violet and Visible Transmission of Eye-Protective Glasses is the title of Bulletin No. 119 issued by the Bureau of Standards and prepared by K. S. Gibson, assistant physicist, and H. J. McNicholas, assistant physicist of the Bureau of Standards. This paper presents a report upon the investigation undertaken by the Bureau on spectral transmission of glasses, and deals with the visible and ultra-violet transmissions. Under this investigation 82 samples of eye-protective glasses were studied in regard to their transmission of ultra-violet and visible radiant energy. Four different methods were used to obtain the desired data, part of the work being done in the physical laboratory of Cornell University and part at the Bureau of Standards. A brief summary is given of the good or bad qualities of the various kinds of glass in comparison with colorless glass as regards protection against ultra-violet radiant energy. A brief elementary discussion is given, explaining the meaning of terms used in spectrophotometry and illustrating how to compute the transmissions for thicknesses other than measures. Sample transmission curves are given with all values plotted, illustrating the kind of agreements and disagreements obtained on the different instruments.

PROPOSALS

Electrical Equipment.—The Board of Education, Buffalo, N. Y., is taking bids for electrical equipment, including motors, control apparatus and other industrial appliances for use in the vocational schools during the coming year. Headquarters of the Board are at 1401 New York Telephone building. William D. Fisher, secretary.

Electric Passenger Elevator.—Bids will be opened in the office of the Supervising Architect, Treasury Department, Washington, D. C., at 3 p. m., July 31, for the remodeling of an electric passenger elevator in the United States post office, court house and custom house at Providence, R. I., in accordance with the drawings and specification, copies of which may be had at the above office in the discretion of the supervising architect. James A. Wetmore, acting supervising architect.

Electrical Fixtures, Etc.—Bids will be received July 28 for furnishing all materials and doing all work necessary to complete the installation of electrical fixtures, lamps, shades, etc., in accordance with plans and specifications for building A. B. C. D. and E. bridge and tower, the industrial arts and power plant group, gymnasium and stadium group of the East Side High Public School building located at Erie and Madison roads, at Cincinnati, Ohio, in accordance with plans and specifications on file at the office of C. W. Handman, business manager, 511 West Court street, Cincinnati, Ohio.

Drills, Press, Pumps.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for 175 electric portable drills, 9/16 inch, 110 volts, universal motor, to be delivered at South Brooklyn, N. Y. (Schedule 4147); a miscellaneous quantity of electric portable drills, two speeds, 125 volts, direct current, delivery at the Philadelphia navy yard (Schedule 4175); one motor-driven trimming press, delivery at Puget Sound, Wash. (Schedule 4172), and 16 main boiler feed turbine-driven pumps for battleships Nos. 49, 50, 51, and 52, and spare parts, delivery at Mare Island, Calif., Norfolk, Va., and Brooklyn, N. Y. (Schedule 4161).

INCORPORATIONS

Mt. Auburn, Ill.—Wurl Electric Light Co. has been incorporated with a capital of $5000, to operate an electric light plant.

Newark, N. J.—Newark Electric Repair Co. Capital, $50,000. To operate a local electrical equipment manufacturing and repair plant. Incorporators: J. S. Jaehnig, L. W. Jaehnig, Newark, and F. H. Walsh, East Orange.

New York, N. Y.—Challenge Storage Battery Corp. Capital, $50,000. To manufacture storage batteries. Incorporators: G. D. Davis, S. and B. Apostuloff, 123 Manhattan avenue.

New York, N. Y.—Multiple Electric Products Co. Capital, $250,000. To manufacture and deal in electrical appliances. Incorporators: J. H. Wallace, Yonkers; E. Frankel, 700 West 179th street, New York, and Andrew C. Knoeller, Jersey City, N. J.

Personal

Bertram Smith Becomes President Automatic Electric Devices—Vinton L. Staley Joins Electric Products Company

J. P. DAVIS, purchasing agent of the Belden Manufacturing Co., Chicago, has been elected second vice-president of the Purchasing Agents' Association of Chicago.

L. J. DRIGGS, construction engineer of the Pennsylvania Public Service Co., at Phillipsburg, is now construction engineer of the Citizens' Light, Heat & Power Co., Johnstown.

FRED B. GROSS, after 20 months' service overseas with the 77th Division, has been honorably discharged and has rejoined the Plant Engineering & Equipment Co. as advertising manager at the new offices at 192 Broadway, New York City.

LIEUT. LINUS G. KNAPP, formerly employed with the Rochester Railway & Light Co., as statistician, has returned to civil life after twenty-two months' service in the army, and is now in charge of the auditing department of the Genesee Light & Power Co., Batavia, N. Y.

J. W. McCABE, who until recently was assistant manager of sales for the Chicago Pneumatic Tool Co., Buffalo, N. Y., has been appointed special representative for the company's foreign trade department and will depart shortly for an extended trip throughout the Orient, Philippine Islands and Australia.

LOUIS MARSHALL REAM, Thompson, Conn., who has been engaged in the inspection of wire for the Government at Washington during the war, has been discharged from the service and resumed his duties as assistant superintendent of the South works of the American Steel & Wire Co., Worcester, Mass.

FOSTER CALLAHAN, recently a first lieutenant of Field Artillery in the United States Army, has returned to civil life as representative in several southeastern states of the Safety Insulated Wire & Cable Co., New York. Mr. Callahan formerly covered this territory in another connection and is well known in the electrical industry.

E. T. COOK, formerly a well known electrical contractor, has joined the sales force of the San Francisco branch of the Trumbull Electric Manufacturing Co. Previous to joining the Trumbull company, Mr. Cook was for 16 months overseas with the 26th Engineers, and while in service rose to the rank of master engineer, senior grade.

SAMUEL F. JOOR, a well known consulting engineer of Chicago, has joined the American Steam Conveyor Corp., Chicago, in the capacity of sales engineer. Mr. Joor has had wide experience in the conveyor field, at one time being western manager and sales engineer of the Jeffrey Manufacturing Co. and previous to that time affiliated with the Link-Belt Co.

BERTRAM SMITH has tendered his resignation as assistant vice-president and general manager of the Edison Storage Battery Co., to become president and general manager of the Automatic Electrical Devices Co.. Cincinnati, Ohio. In severing his connection with the former company Mr. Smith terminates over twenty years' service in the storage battery industry, having been secretary and treasurer of the Old National Battery Co., which marketed the "Sperry plate." After its absorption by the United States Light & Heating Co., he was for a number of years manager of the western territory with headquarters at Chicago. In 1913 he resigned to become assistant manager of the Edison Storage Battery Supply Co., on the Pacific Coast, with headquarters at San Francisco, and two years later was appointed manager of the Detroit sales district of the Edison Storage Battery Co., Orange, N. J. In this position Mr. Smith established a record for the sale of Edison batteries. In September, 1918, he was promoted to the position of assistant vice-president and general manager, and continued in this capacity until his recent appointment with the Automatic Electrical Devices Co.

Bertram Smith.

GEORGE H. WARING, for the past two years general manager of the Utah Gas & Coke Co., Salt Lake City, has been elected to the office of vice-president and assistant general manager of the American Public Utilities Co., Grand Rapids, Mich., and will have general supervision of all the plants and properties owned by that concern and Kelsey, Brewer & Co. He is one of the foremost gas engineers in the United States and an all around public utility operator of wide experience with a very successful record. Mr. Waring was born at Cement, Bartow county, Ga., in 1871, and was graduated from the Alabama Polytechnic Institute in 1890 with the degree of Bachelor of Science. He entered the gas business in 1892 as cadet assistant to the superintendent of the gas company in Atlanta, Ga. In 1895 he joined the construction engineering force of the United Gas Improvement Co., and superintended the rebuilding of the gas plant at Kansas City, Mo. From 1910 to 1917 he served as vice-president and general manager of the Consolidated Railway & Lighting Co., Charleston, S. C., resigning that position to accept the appointment of manager of the Utah Gas & Coke Co. Mr. Waring was a charter member of the American Gas Institute, the Illuminating Engineering Society and other organizations.

GEORGE ELTZ, after resigning his commission in the navy, has returned to the research laboratory of the Western Electric Co. Mr. Eltz was associated with naval aviation radio.

R. E. BURGER, president and general manager of the Richland Public Service Co. of Ohio, has tendered his resignation to become chief engineer of Henry L. Doherty & Co., public utility operators, New York City.

VINTON L. STALEY, formerly connected with the General Electric Co. as district sales manager of the Edison Lamp Works at Pittsburgh, Pa., has become associated with the Electric Products Co., Cleveland, Ohio, in the capacity of sales engineer. During the war Mr. Staley held a commission as lieutenant in the Chemical Warfare Service, being stationed at Nela Park, Cleveland, Ohio. Since leaving the service he has been connected with the Powdered Coal Engineering & Equipment Co., Chicago, as sales engineer.

EVAN F. JONES has been appointed president and general manager of the Clinton-Wright Wire Co., Worcester, Mass., a merger of the Wright Wire Co., Worcester and Palmer, Mass., the Morgan Spring Co., Miller Wire Cloth Co., National Manufacturing Co., Worcester, and Clinton Wire Cloth Co., Clinton, Mass. Mr. Jones was formerly purchasing agent of the International Harvester Co. in Chicago and later was connected with the Birmingham Steel Co., Birmingham, Ala. About 11 years ago he removed to Worcester, Mass., when he accepted the appointment of general manager of the Morgan Spring

CHARLES W. COLLIER, who for the past 18 months has been overseas in the national service, has returned to this country and has resumed his advertising work in the publicity department of the St. Louis Brass Manufacturing Co., manufacturer of the Brascolite and various other well-known lighting units. Up to two months ago Mr. Collier was in France with a hospital unit attached with the British, and during that time has had various opportunities to study the French and English methods of printing and newspaper production. Mr. Collier was formerly assistant secretary-treasurer of the St. Louis Advertising Club, and later advertising manager of Kline's.

of the horizontal reaction type

Allis-Chalmers Steam Turbine and Alternator units have earned an enviable record for efficiency and reliability, and the fact that a large proportion of our output is for customers already using our equipment indicates the operator's confidence in our apparatus.

The units are of the straight reaction type, possessing many special and desirable features.

A complete line of standard units ranging in size from 200 K.W. to 12500 K.W. has been developed to meet the most exacting conditions of service.

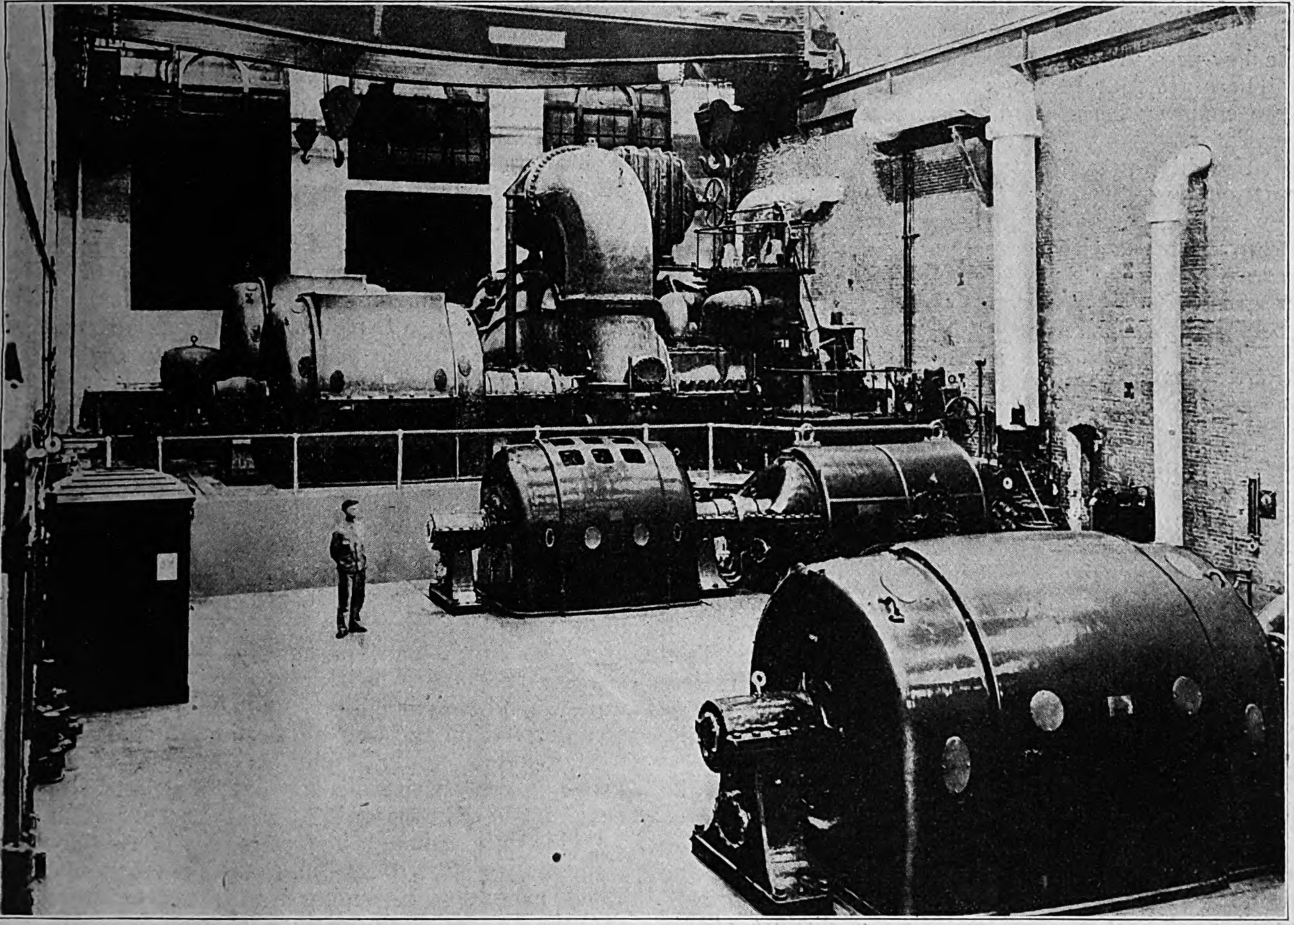
VOL. 75—No. 3. CHICAGO, SATURDAY, JULY 19, 1919. PAGE 91.



45,000-Kw. Westinghouse Turbogenerator Operating in Station of Narragansett Electric Light Company, at Providence, R. I.

The 45,000-Kw. Turbine-Generator Set at Providence

Huge Cross-Compound Unit of the Narragansett Electric Light Co.—Unique Features of the Two Turbine Elements

THE Narragansett Electric Light Co., at Providence, R. I., recently put into operation a 45,000-kw. turbogenerator unit. This machine is of the cross-compound double-unit type, consisting of a high and low-pressure turbine, each connected through a flexible coupling to its own generator, having a capacity of 22,500 kw., and mounted on separate bedplates supported on foundations lying parallel to each other. The generators are arranged to feed separately or together to the main bus.

This type of turbine is very successfully exemplified by the three 30,000-kw. units installed a few years ago in the 74th street station of the Interborough Rapid Transit Co., New York City, and which have attracted a great deal of attention.

DETAILS OF THE TURBINES.

Steam enters the high-pressure turbine through suitable governor-controlled valves, passes through this single-flow element, out through an exhaust on the top, and is conducted by means of a receiver pipe overhead to the middle of the double-flow low-pressure turbine alongside, where it divides, flowing in opposite directions through low-pressure blading, then down through the exhaust chambers into two Westinghouse LeBlanc jet condensers of the latest type.

The energy given up by the steam at full load is equally divided between the high- and low-pressure turbines, the generators dividing the load in half; at lower loads a greater proportion is carried by the high-pressure element.

The unit was designed to operate with a steam pressure at the throttle of 200 lb. with 100° F. superheat and a vacuum of 29 in. in the exhaust. The generators have a capacity of 23,750 kv-a., at 11,000 volts, 3-phase, 60 cycles and 0.95% power-factor. The high-pressure element has a speed of 1800 r. p. m., the low-pressure element of 1200 r.p.m.

There are four bearings to each unit, a flexible pin type coupling being used to connect the turbine and generator.

The high-pressure turbine is of the single-flow reaction type throughout, of simple, rugged construction; all parts coming in contact with high-pressure steam are made of cast steel, while the exhaust chamber and other parts not subjected to high temperature or stresses are of cast iron. The pressure in the high-pressure cylinder varies from a maximum of about 200 lb. at the inlet to atmospheric pressure in the receiver pipe at full load.

The high-pressure end, or steel part of the cylinder, is composed of two steel castings, 5 ft. 10 in. inside diameter and 1¾ in. thick, while at the joint thickness gradually increases until it merges into a flange 3 in. wide, tapering to the outer edge. The 2¼-in. diameter bolts are spaced about one-third of the way from the inside edge, and 6 in. between centers. These bolts, or studs, as they really are, are tapped alternately into upper and lower flanges registering with suitable bosses on the companion flange. This method permits of a closer spacing of bolts, removing less metal, and produces a stronger flange than by any other means. No gasket is used, the joint being scraped to a surface.

The four rings containing the blades are not an integral part of the main cylinder, but are made of separate castings jointed in the middle, resulting in simplicity of construction, freedom from strains, and the absence of those difficulties inherent in a complicated steel casting, besides being a distinct aid in manufacturing as the machine work is not all done on one piece, but can be divided among different machines, and finally assembled when each piece is completed. These rings are clamped in place, again saving expensive work on the main castings.

The high-pressure cylinder is supported on three points, one under the governor, or thrust end, and one on each side of the exhaust, near the center line, thus insuring against distortions, or a possibility of misalinement, due to differential expansions between the turbine and generator supports from unequal temperatures.

The high-pressure spindle consists of a hollow steel drum about 3 ft. in diameter, carrying most of the blading, there being two blade rings of larger diameter on the one end, and corresponding dummy rings, or balance pistons, on the other. The spindle ends are pressed into the drum and are secured with tee-headed shrink links, which are themselves held in place by the blade and dummy rings. The spindle parts are made from ordinary carbon steel. There are 24 rows of blades in the high-pressure turbine, ranging in size from 1-in. blades, 4 in. long, to 1¼-in. blades, 9½ in. long. These blades are unusually strong and rugged. The maximum mean blade speed is 470 ft. per second.

The steam passes out through an exhaust at the top of the cylinder into a 66-in. receiver pipe leading over to the low-pressure turbine. A similar exhaust which connects through an automatic relief valve to the atmosphere is provided directly below. A gate valve is placed in the receiver pipe, in case it is necessary to operate either turbine alone, the high-pressure turbine running non-condensing, under control of its own governor, or the low-pressure turbine, on steam admitted through a 14-in. throttle from the high-pressure line. This is connected in step electrically with some other unit in the system.

The low-pressure element is of the straight double-flow reaction type. The steam entering at the top through the above mentioned receiver pipe, passes around the spindle in an annular chamber of ample proportions, and enters the low-pressure blading, there being 8 rows in each end, ranging from ¾-in. blades 6 in. long, to 1¼-in. blades 18 in. long. The low-pressure cylinder rests on four supports applied near the center line on each side of the exhaust chambers. It is free to expand by sliding axially on these supports, the turbine being anchored to the inboard generator pedestal. A system of radial and axial stays in the exhaust chamber produces extreme rigidity, minimizing the possibility of distortion, or sympathetic vibrations.

The low-pressure spindle is composed of a central hollow drum, rigidly secured to the spindle ends. Upon each of these ends are mounted two disks carrying the low-pressure blades, the maximum mean velocity of which is only 515 ft. per second. Cast steel is used for the blade rings. Phosphor-bronze blades are used throughout, except the last three rows in the low-pressure, which are forged steel. The low-pressure cylinder is entirely of cast iron, composed of a center section and two end sections, bolted and spigoted together, and all split horizontally. The three upper pieces are handled as one, the vertical points never being disturbed.

This unit, although it does consist of two separate elements, is started the same as any other machine. Field excitation is supplied to the generators, the throttle on the high-pressure element is open, and slowly brought up to speed, the low-pressure generator operating as a motor, and coming to speed in step with the other. The two machines as a unit can then be synchronized, and placed on the line, remaining in step, and properly dividing their load.

Condenser Equipment.

The condenser equipment for the above turbine consists of the largest condensing apparatus in the world. The condenser unit is composed of two separate and distinct low-level jet condensers, which can be operated together, or separately, if necessary. If the temperature of the injection water is low enough to warrant it, a workable vacuum can be maintained by only one condenser. These condensers are connected to form a single condensing apparatus by means of an exhaust connection, ample in area to permit operating either condenser alone, when necessary.

The same water level is maintained in each condenser by the use of a water-equalizing connection between one pump body and the other. This is an absolutely necessary feature, and it is provided in order to maintain a constant submergence over the center line of each pump, to provide sufficient head to force water into the runner under vacuum. This water-equalizing connection is so constructed that no surges occur between the condensers, it being made in the form of a toe, the bottom of which forms a reservoir. A baffle running almost to the bottom prevents surging. An air-equalizing connection is provided to maintain the same air pressure in each condenser. If both are in operation, the valve may be either open or closed, but it has been found by trial that if only one condenser is in operation, the valve must be open in order to have the same air pressure in each.

The condensers are equipped with geared turbine-driven pumps, running at 500 r. p. m. instead of 700 r. p. m., which latter is standard. This was necessary owing to the limited headroom in the basement. These pumps are able to operate with a submergence of 50 in. above the center line of the pump shaft, while 72 in. is necessary with a 700 r. p. m. pump. This resulted in a saving in headroom of 22 in.

In starting up this condenser it is necessary to use a priming pump. The main turbine is operated non-condensing, or with a slight vacuum, until sufficient vacuum is obtained for the condenser to lift its own water.

The Narragansett Electric Light Co. has found it convenient in winter time, when the temperature of the injection water is very low, to operate only one condenser of the twin outfit, and still maintain the vacuum desired, thereby cutting the cost of operation in half. In cutting the condensers out, it is only necessary to close the discharge and injection valves to the condenser not in operation and to operate the other independently.

The twin condensers used with the above 45,000-kw. turbine require 18,000,000 lb. of condensing water per hour. 9,000,000 lb. in each condenser. In addition to this 15 per cent more is required for the operation of air pumps.

BEACON LIGHTING EFFECT FOR TRAVELERS INSURANCE TOWER.

A Total of 56 Projectors to Produce Very Striking Beacon at 34th Floor Level.

One of the questions that has been a frequent subject of conjecture among watchers of the new building of the Travelers Insurance Co., Hartford, Conn., was answered a few days ago when it was learned there would be a beacon near the top of the tower which would rival in brilliance and radiative power the beacons in other of the world's famous tall buildings.

Plans relative to the lighting features of the Travelers tower have been made and unmade many times since the erection of the building was begun, but the plan of the beacon has been definitely settled upon. Anyone who can catch a glimpse of the work going on just above the limit of the stonework may see what is going to be put there.

Next above the limit of the stonework, at the thirty-fourth floor level, and below the gilded ironwork which surmounts the tower, there is being built a row of windows running in close continuity around the four sides of the superstructure. Each window is about 4 ft. high and 1 ft., 4 in. wide.

Suspended inside these windows will hang 36 400-watt projectors, 8 to each side and one in each corner, and 8 200-watt projectors, two in each corner on either side the large corner projector. These projectors will throw the light in every direction outward through the windows, so as to give the appearance of a continuous band of brilliant light circling the top of the tower and shining out from it.

Another feature of the tower lighting will be the illumination of the interior of the observation balcony by 12 hidden projectors. Current for all the projectors will be carried into the tower from the city lighting system. It is supposed that the beacon and balcony will be lighted every night, once they are ready for operation. From present appearances, it would seem that the work on the superstructure would not be completed for several weeks yet, possibly not until late summer or early autumn.

DEDICATION OF THE BUREAU OF MINES LABORATORIES.

New Laboratories, Shops and Experiment Station at Pittsburgh to Be Formally Dedicated.

The Bureau of Mines announces that during the week of Sept. 29 the new million dollar laboratories and workshops in Pittsburgh, Pa., will be formally dedicated. High officials of the Government, together with the governors of the principal mining states and the leaders in the mining industries and miners' organizations, will be present to take part in the dedicatory ceremonies. A feature of the dedication will be a great national Safety-First meet, teams of miners from all over the country competing for cups and medals. There will be contests in rescue and in first aid to the injured, and as there is immense rivalry between the teams of the different mining companies, it is expected that these contests will take at least two days for decision. On Sept. 30 the elimination contests will begin at Forbes Field in Pittsburgh, and will continue until only the winning teams are left for the final championship contests, which will take place on Oct. 1 immediately after the elimination trials are completed.

The different laboratories of the Bureau have been completely equipped for the investigation of the various problems relating not only to greater safety, but also to greater efficiency in the mining and metallurgical industries. Visitors will be invited to the electrical and mechanical workshops, and laboratories of the Bureau and also to the petroleum, gas and coal laboratories, the testing gallery of the mine safety section, and the industrial gas-mask division. Another point of interest will be the experimental mine of the Bureau at Bruceton, Pa., twelve miles from Pittsburgh, where an actual explosion of coal dust in the mine will be staged for the benefit of those attending. At the experimental station there is also to be shown a complete exhibit representing the mining and metallurgical industries of the country.

MORE SIGNS FOR SALINA.

Santa Fe avenue will assume the earmarks of Broadway on a small scale at the end of the calendar year, the Salina Light, Power & Gas Co., of Salina, Kansas, has announced, making public its plans for increasing the number of electric signs in the city.

Lamps totaling 29,500 burn in electric signs until midnight daily. The show windows over the city burn nightly 750,000 watts of electricity. The four-sided "Tea Table Flour" sign of the Weber Milling Corp., largest in the state, measuring 48 ft. by 38 ft. on each side, will be lighted shortly. The sign being erected for the Southwest Motor Car. Co. will be lighted in the near future.

Central-Station Rates in Theory and Practice

Second Article of Series—Cost Analysis of Electric Service—Energy Cost and Demand Cost—Some Features Determining Demand Cost—Load Curve and Load-Factor

By H. E. EISENMENGER

This is the second article of a series to appear weekly throughout this volume. A general outline of the series was published in the issue of July 5 and the first article appeared in the issue of July 12. It gave a discussion of costs in general and introduced the subject of cost of electric service in particular. The present article begins the discussion of the three principal elements of this cost, which will be continued through several other installments before the subject of the price of the service (rates) can be intelligently taken up.

PART I.—THE COST OF ELECTRIC SERVICE—(Continued).

II-A. The Three Elements of Cost.

1. The Energy Cost.

SECTION 11. Every kilowatt-hour generated or delivered requires a certain amount of steam—at least in case of steam prime movers—and with that of fuel and water. In other words, the total costs of fuel and water increase with the number of kilowatt-hours generated and can be roughly set proportional to the latter so that we have a fixed unit cost of fuel and of water per kilowatt-hour. The items of fuel and water do not appear in hydroelectric plants; but in all central stations, whatever their prime motive power be, we have the cost of lubricating oil which increases with the size of the generator running, with the number of generators running and with the number of hours they are running. In other words, for a given central station the cost of the lubricating oil increases with the number of kilowatt-hours generated and can be roughly set proportional to the latter so that here too we have a fixed cost per kilowatt-hour. The same applies to the cost of attendance to the generators and the switchboards, to repairs and a number of other items.

This part of the cost, the energy cost, is also called sometimes, though not entirely correctly, the operating cost. We will see that a part of the real operating cost may belong to the "demand cost" (to be discussed in Section 24) and, conversely, the kilowatt-hour cost includes costs which are not operating cost. But, on the whole, roughly speaking, the kilowatt-hour cost and the operating cost are more or less identical.

12. As indicated previously in the example of the letter carrying service, we can establish a distinction in the amount of the energy cost per kilowatt-hour between various classes of customers. The most important one of the possible subdivisions into classes would probably be according to the distance of the customer's location from the generating station, inasmuch as generally a larger portion of the energy is lost in transmission if the energy has to be transmitted over a greater distance. We would be justified in saying that those customers who are located further away from the generating station cause a greater energy cost per kilowatt-hour than those who are located nearer the station and we might find the numerical values by methods similar to those to be shown later. But this distinction according to the location is rarely, if ever, made in practice.

Other variations in the amount of the energy cost per kilowatt-hour will be mentioned later (especially in Section 53) after the necessary fundamentals (load-factor, diversity-factor, etc.) have been discussed.

13. Let it be stated here—although that statement ought to be unnecessary for the careful reader—that the "energy cost" or "kilowatt-hour cost" is something entirely different from the "cost per kilowatt-hour." The cost per kilowatt-hour is the total annual cost of the central station divided by the number of kilowatt-hours generated (or delivered, or sold, as the case may be) anually, and is given in *dollars per kw-hr.* or *cents per kw-hr.* The kilowatt-hour cost (or energy cost), on the other hand, is a certain portion of the central station's total annual cost, corresponding roughly to the annual operating cost. It is given in *dollars per year.* Usually we reduce the kilowatt-hour cost to the kw-hr. generated or sold annually and thus arrive at the *kw-hr. cost per kw-hr.* or *energy cost per kw-hr.*, which is given in dollars per kw-hr. or cents per kw-hr. The kw-hr. cost per kw-hr. is a fraction of the total cost per kw-hr. By multiplying the kw-hr. cost per kw-hr. by the number of kw-hr. consumed annually by a certain consumer, we get the annual kw-hr. cost of that customer as a part of his total annual cost.

It is important to keep these distinctions between the kw-hr. cost and cost per kw-hr. in mind to avoid confusion.

2. The Demand Cost.

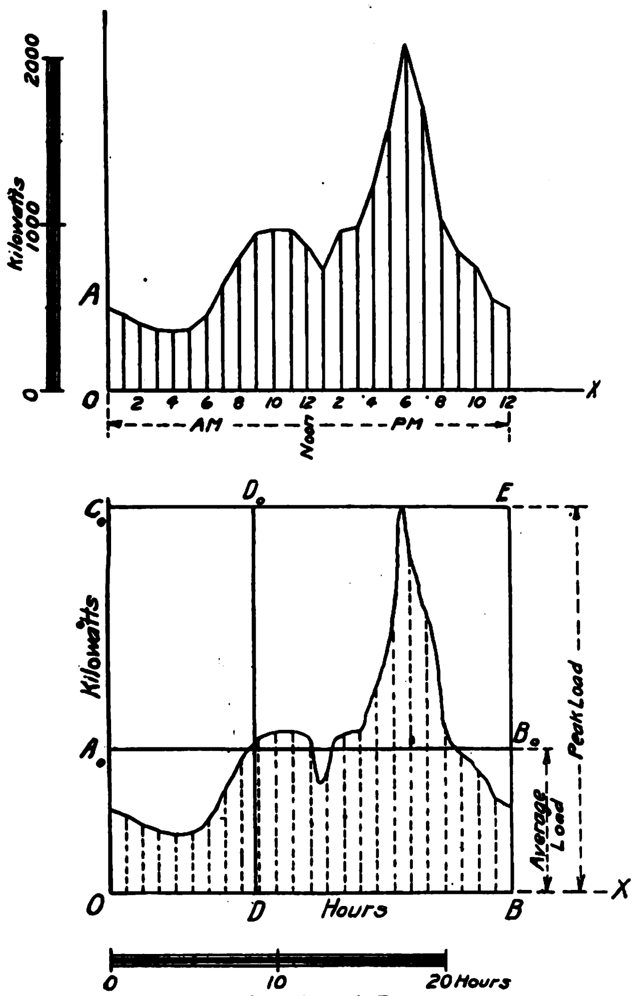
14. The second item to be discussed is the *demand cost*, that is, the part of the total cost which is practically proportional to the maximum demand in kilowatts or watts.

A. THE TOTAL DEMAND COST OF THE PLANT.

1. Capital Invested.

15. Suppose, for the sake of a simple example, that a central station has to deliver 24,000 kw-hr. a day with constant load on the generators all day; that means 1000 kw-hr. in any one-hour period of the day. To supply this, our generators, apparatus, lines, etc., have to have a capacity of 1000 kw. The load-factor[1] is 100%. If, however, these 24,000 kw-hr. would have to be delivered in six hours, for instance in the time between 4:00 p. m. and 10:00 p. m., again with constant load during these hours, the load of the central station will reach 4000 kw., because 4000 kw. × 6 hr. = 24,000 kw-hr. The capacity of the central station will, therefore, have to be four times as great as in the first case, or 4000 kw. instead of 1000[2]. Now a central station of 4000 kw. will cost, though not four times as much, still a good deal more than a 1000-kw. station. The same applies to the transmission and distribution lines, transformers, etc.

16. As a rough approximation we can say that the capital invested is proportional to the capacity of the central station in kilowatts. It should not be forgotten that this is an approximation. It is a well



Figs. A and B.

known fact that as the central station grows, the cost of the equipment per kilowatt goes down. Larger plants can use larger generating units than smaller plants and such units are not only cheaper to manufacture per kilowatt, but they occupy also less floor space per kilowatt, thereby reducing the cost of the building construction, etc., per kilowatt. The same applies to switching apparatus, etc. Moreover, even generating units of the same capacity have been becoming cheaper as the engineering sciences advance.

But as long as we remain within certain upper and lower limits of size near the present plant capacity, also when we do not apply our approximation over a period of too many years, we can assume the capital invested in the generating plant to be proportional to the capacity. If the central-station capacity has grown very much, especially if the manufacturing conditions have changed in the meanwhile, the factor of proportionality will have to be changed; there will be less capital invested per kilowatt in the generating station.

17. Similar considerations as have been explained for the cost of the power plant will also apply to the transmission lines, transformers, etc., so that we may say with a certain degree of approximation that the cost of these parts also is proportional to the peak load of the central station[3].

We thus arrive by a series of approximating assumptions at the result that the total capital invested in the generating plant, lines and transformers is proportional to the peak load of the central station[4].

Insert II—Appendix to Section 15.

Explanation of the Terms "Load Curve" and "Load-Factor."

A.—Load Curve.

Step off on a horizontal line *OX* in Fig. A, 24 equal sections, each one representing one hour of the day. From the end of every one of these sections draw a vertical line upwards and step off on these, beginning at their respective intersection with *OX*, the load in kilowatts of a certain central station at that particular hour, using some arbitrary scale, for instance 1 in. = 1000 kw. If, for example, at 12 o'clock midnight the load is 500 kw., step off ½ in. vertically from the point *O*, thus reaching point *A*. Do the same thing for every full hour of the day (1 o'clock, 2 o'clock, etc.). Joining the point at the upper end of each vertical with both its neighbors to the right and left by a straight line we get a continuous series of straight lines. We are not restricted to entering the loads at the full hours only. We can enter them in the same way for any intermediate time; as quarter hours, minutes, etc., and the series of lines will then more and more approach in any desired degree a steadily curved line (Fig. B).

This curve is called the *load curve* of the central station for the respective day. The load curve can, of course, also be extended over any other interval of time, but usually a 24-hour interval is chosen for reasons of convenient representation. This curve shows clearly at a glance how the load varies within the day. Where it is high above the horizontal axis *OX* the load is large and vice versa. The high parts of the curve are called the peaks and the low parts the valleys. The highest peak represents the peak load, hence the name of the latter.

In exactly the same manner we can draw a load curve for any individual customer or any group of customers.

The general shape of the diagram, Fig. B, is typical for what we can expect in an average central station on an ordinary winter day. Beginning at midnight we see the load is comparatively low, naturally so, because most of the customers have shut off their current entirely. The load is mostly street lighting and street-car service, provided that the latter is not furnished from the street-railway company's

[1] Readers who are not thoroughly familiar with the meaning of the terms "load-factor" and "load curve" should first read Insert II, which gives an explanation of these terms so essential for the understanding of the following sections.

[2] This is not strictly correct, since there must be a certain reserve capacity for breakdowns of a generator set, and the reserve capacity will obviously in general be a greater percentage of the total capacity where we have a small number of generating units than where we have a large one, that is, it will be in general a greater percentage for smaller capacities. But, as a whole, the approximating assumption that the capacity of a central station is proportional to the maximum load of the central station is justifiable.

[3] This implies an additional simplifying assumption, because it is evident that the cost of the lines and transformers depends also on local conditions, that is, on the location of the customers, etc., but, on the whole, in a given locality we can say, that the variable portion of the cost of the lines and transformers will increase roughly in the same percentage as the maximum load on the central station.

[4] These assumptions are, briefly recapitulated, the following:
1. The capacity of the power house is proportional to the peak load.
2. The capital invested in the power house is proportional to the capacity of the power house.
3. The capital invested in the lines, transformers, etc., is proportional to the peak load.

These and the other approximations, to be discussed in the following, will be put together in diagrammatical form at the beginning of Insert IV—"Approximations."

separate power house. A few late birds who are still up at midnight go to bed by and by and the load reaches a minimum until the first early risers turn on their lights. The demand for this kind of lighting rises until daylight comes and then it may decrease. At that time, however, the factories begin to work, drawing a rather heavy power demand. Such stores and offices as need artificial illumination in daytime turn on their lights and thus we get an increase in the load during the earlier part of the forenoon. The motors in the factories which consume a considerable portion of the power generated are then shut off temporarily during the noon hour and accordingly we see a valley in the load curve at noon. At about 4 or 5 o'clock in the winter time the electric lights are turned on everywhere and we get the highest peak of the day. Soon after that time stores and offices close, causing a rapid falling off of the curve.

Of course the daily load curves of central stations differ from each other quite considerably according to the season of the year and to the local conditions[1].

The load curve gives us more information than simply whether the load at a particular time is high or low. The area under the load curve is a direct measure of the number of kilowatt-hours delivered, in other words, it is proportional to the energy delivered (or consumed, respectively). To understand this let us begin with a simple case. A central station is assumed to be delivering 1000 kw. uniformly during 24 hours of the day. Then the number of kilowatt-hours delivered during the day will be 24,000. The load curve will be a rectangle, the height of which is 1 in. (if measured in the scale selected above for the purpose), that is, 1000 kw. The base of the rectangle is, of course, a length representing 24 hours. Since the area of the rectangle is given by the product of base and height, or in our case by $24 \times 1000 = 24{,}000$, we see that in this simple case the area under the load curve is equal to the number of kilowatt-hours. The same will be true not only for a 24-hour period, but also for any other period of time. For instance, if we have 100 kw. during ½ hour, the resulting energy is $100 \times \frac{1}{2} = 50$ kw-hr. and at the same time the area under the rectangle, which is the load curve in this case, is also $100 \times \frac{1}{2} = 50$ units.

If we have different loads in successive periods of time of equal length, for instance, the load changing every 15 minutes, Fig. C, the load curve will be a number of rectangles arranged side by side and the total number of kilowatt-hours will be the sum of the kilowatt-hours delivered (or consumed) in the various periods. The area under the load curve will be the sum of the areas of the individual rectangles. Therefore, in this case also the number of kilowatt-hours is given by the area under the load curve. Now, if in a load curve of that kind the rectangles become narrower and narrower, at the same time increasing in number so that the total horizontal length of the diagram remains constant, the same law will always hold good, no matter how short the periods of time are.

Now we can disintegrate the area under *any* load curve into a number of narrow high rectangles and their aggregate area will equal the area under the original curve the more exactly the larger the number of the rectangles and the smaller consequently their width (Fig. D). We can make the error smaller than any desired limit (however small that may be) by making the rectangles numerous enough. Therefore, we can also say quite generally that the area under any shape of load curve is proportional to the number of kilowatt-hours, that is, to the energy. The unit area is a rectangle with the base, 1 hour, and the height, 1 kw.; it corresponds to 1 kw-hr.

B.—LOAD-FACTOR.

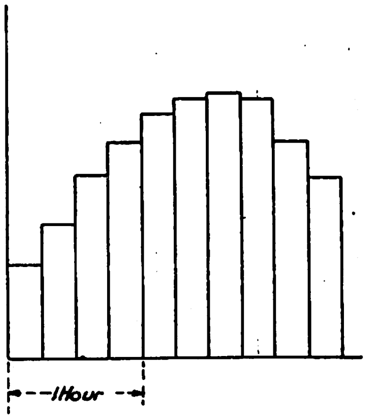
The easiest way to arrive at a conception what the term *"load-factor"* means seems to be to start from the "average load" (or, as it also may be called, the "average power") of a certain period. That is, a load of such size that, if uniformly and without change supplied by the central station (or drawn by the consumer, as the case may be) over a certain period, it results in the same number of kilowatt-hours as are supplied (or consumed) under actual conditions during that period.

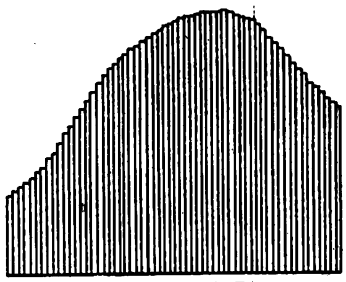
If we transform the area under a given load curve into a rectangle OA_0B_0B (Fig. B), having the same base, OB, as the load curve, the height OA_0 of that rectangle is the average load during the period over which the load curve extends. The reason why this is so is easy to see: This load, OA_0, if supplied during the period OB, results in the number of kilowatt-hours given by the area of the rectangle OA_0B_0B, which means it results in the same number of kilowatt-hours as have been actually supplied or consumed, which means it is the average load.

a.—First Definition of Load-Factor.

The ratio $\frac{\text{average load}}{\text{peak load}}$, or, in other words, $\frac{\text{average power}}{\text{maximum power}}$, is called the *load-factor* of the central station (or consumer, or group of consumers) for the given period of time. It is usually given in per cent. The load-factor belonging to the load curve Fig. B would, therefore, be the ratio, $\frac{BB_0}{BE}$ or 37%. This would be the daily load-factor of a certain day, because the load curve extends over one day. In practice, however, the load-factor is much more frequently referred to either the year or the month, so that we have a yearly or a monthly load-factor.

Since the load curve extending over a month, not to say a year, with its numerous large fluctuations, is a very complicated curve and it is impossible to find a convenient





Figs. C and D.

scale for its practical use, the following definition—which in effect is identical with the above— is preferable.

b.—Second Definition.

If we multiply the numerator and the denominator of the above ratio by the number of hours of the whole period (month or year) the value of the ratio is not changed but the ratio takes another form. The average load multiplied by the period over which it extends is, according to the definition of the average load, equal to the number of kilowatt-hours actually supplied (or consumed). The peak load multiplied by the same period is the maximum number of kilowatt-hours which could possibly be supplied (consumed) with the given maximum power in that period, that is, the number of kilowatt-hours which would be the result of the maximum amount of power applying during the whole period. Therefore, the load-factor can be also defined as a percentage expressing the ratio of the energy actually supplied (consumed) to the energy which could be supplied (consumed) in the same time if the maximum load was utilized during the whole time.

The load-factor according to this definition can be easily determined. The actual number of kw-hr. is determined by an ordinary integrating watt-hour meter, and the energy in kw-hr. which could be supplied (consumed), if the maximum load was utilized during the whole time, is

[1] Fig. L. (Insert VII) will show the load curve of a December day and of a June day of the same central station. It shows how the evening lighting peak in June not only is smaller (due to less commercial lighting) but also comes much later than in December.

simply found as the product of the maximum load in kw. by the length of the time over which the load-factor is to be taken, in hours. The maximum load can be found by an instrument known as a demand meter (to be described in Section 140 and Insert XVI).

c.—Third Definition.

Finally, we can also assume that the actually supplied (or consumed) energy has been produced by the maximum load uniformly and steadily applied. It will require a certain period of time until the energy is thus supplied and the ratio of this time to the total time over which the load-factor is taken (one month or one year) is also equal to the load-factor, as can be easily shown graphically (see below). The load-factor is then expressed in terms of "hours per year" or "hours per month," respectively. A load-factor of 10% can therefore be expressed as a load-factor of 876 hours per year (since the year has 8760 hours) or as a load-factor of 73 hours per month (since the average month has 730 hours), depending on whether the load-factor in question is a yearly or a monthly one.

The graphic representation of and proof for this third form of definition of the load-factor is given by transforming the area under the actual load curve into a rectangle of the same area with the maximum load as height. This rectangle OC_0D_0D (Fig. B), therefore, is equal to the energy actually supplied (or consumed); the large rectangle OC_0EB represents the maximum energy which could possibly be supplied (consumed) in the given period with the given maximum power OC_0. The ratio of the rectangles is the load-factor according to the second definition given above of the load-factor. The ratio of these two rectangles is also given by the ratio $\frac{OD}{OB}$, therefore $\frac{OD}{OB}$ is the load-factor.

Where the maximum load is replaced by one of its substitutes (as will be shown in Section 141 *et seq.*, of the main text—"Substitutes to Approximate the Measured Maximum Demand") the load-factor can also be based on one of these substitutes, notably the connected load instead of on the actual maximum load.

(*To be continued.*)

PROPOSED TUNNEL BETWEEN DENMARK AND SWEDEN.

Electric Railway Line to Connect the Two Countries Through the 31.5-Mile Tunnel.

It appears that the Channel Tunnel between France and England has a rival in a tunnel which it is now proposed to construct from Copenhagen, Denmark, in order to make connection with Sweden, states *The Electrician,* of London, England. The main line from Copenhagen, it is suggested, might connect across a harbor dam with the island of Amagar, the tunnel being entered on the eastern coast of the island, while another adjacent island (Saltholm) would serve as a convenient starting place for sinking shafts and tunnelling in two directions. The total length of the line, which will have four intermediate stations, will be 31½ miles, the actual length of tunnel below the surface of the sea being 11 miles.

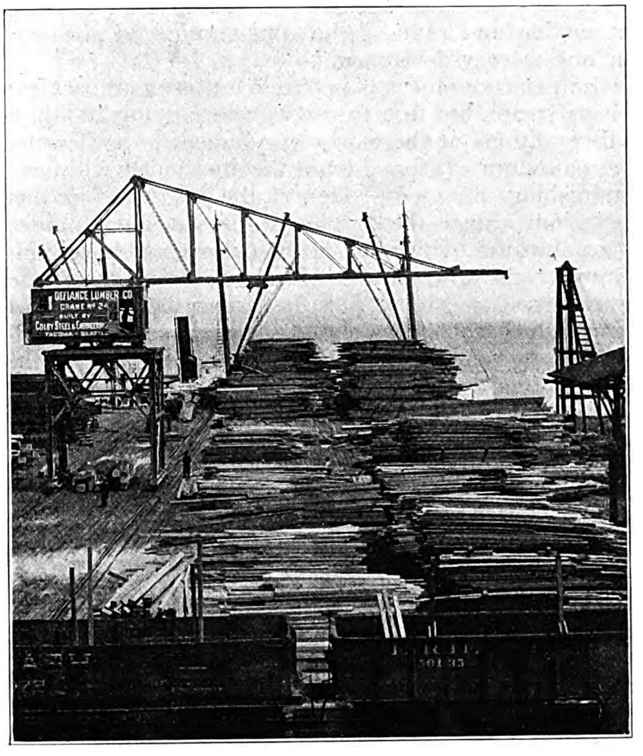
The line is to be supplied electrically from a power station on the isle of Amagar. Initially there will be only a single track, but ultimately two tracks will be available. The bore of the tunnel will be 20 ft. 6 in. The pre-war estimated cost was about $25,000,000.

FLOOD LIGHTS AID IN FIRE-FIGHTING.

At a recent demonstration conducted by the fire department of Dundee, Scotland, it was shown that flood lighting has valuable possibilities as an aid to fire-fighting at night. A floodlight projector mounted upon a tripod frame and equipped with a 1000-watt Mazda C lamp was used. By means of the powerful beam it was possible to identify a fireman working at a height of 400 ft. Although in many cases the light from the fire itself provides sufficient illumination to guide the firemen, very often the members of the department are compelled to work in comparative darkness, which is not only a serious drawback to effectiveness in their work but constitutes a serious life hazard under these conditions. The projector that was used can be operated from a small generator mounted upon the fire engine or it can be supplied from any available central-station circuit. The projector is easily portable.

ELECTRIC REVOLVING BOOM CRANE FOR HANDLING LUMBER.

Facilities for the rapid and economical handling of lumber from sawmills to storage and from the latter to ships or cars, have reached a high stage of efficiency in the use of the revolving gantry crane with horizontal boom, operated by either alternating-current or direct-current motors. A crane of this type lately installed at the mill and shipping dock of the Defiance Lumber Co., Tacoma, Wash., made by the Colby Steel & Engineering Co., Seattle, has 5 tons capacity and is



Electric Crane in Use Handling Lumber.

operated by a 35-hp. motor. The mechanism for the hoist and crane movements is made up of one unit in the cab. By this means the boom revolves in a complete circle, and the operator is able to travel the crane on the track, move the boom in either direction, hoist or lower the load and travel the trolley in or out, all at the same time. Other cranes of this type of 5 tons and 10 tons capacities are in use at shipyards on Puget Sound, where rapid handling of material is required.

ELECTRIC TRUCKS MAKE THEMSELVES KNOWN IN NEW YORK CITY.

Of the total number of trucks in operation in New York City, 10% are said to be propelled electrically. In round figures, there are about 33,000 trucks in operation, those using storage batteries numbering 3288. Before the next year, the number of electrics will be considerably augmented.

The Still Engine — A New Prime Mover

Utilization of Fuel and Cooling Medium Features of the Engine—High Thermal Efficiency and Low Unit of Weight Are Other Valuable Properties — Special Applications

THE Still engine is an engine capable of using in its main working cylinder any form of liquid or gaseous fuel hitherto employed; it makes use of the recoverable heat which passes through the surfaces of the combustion cylinder, as well as into the exhaust gases, for the evaporation of steam, which steam is expanded in the combustion cylinder itself on one side of the main piston, the combustion stroke acting on the other side. It increases the power of the engine and reduces the consumption of the fuel per horsepower developed.

Its primary object is not to use the waste heat for raising steam, but first to use it in improving the thermal conditions of the working cylinder, and so ensure the maximum efficiency from the fuel burnt within it, diminishing, as a consequence, the heat lost in that operation. Since the maximum efficiency is obtained by combustion of the fuel in the cylinder and the minimum by the evaporation of the water in the steam generator, it is evident that the larger the quantity of steam which can be generated per horsepower developed by the combustion cycle, the lower must be the heat efficiency of the whole machine.

Internal-combustion engines are kept cool by the circulation of cold water around their cylinders; the heat thus absorbed causes a rise in temperature of the water as it travels through the jacket, so that the cylinder is subjected to temperature differences and heat stresses, which are an abiding source of trouble and difficulty to the designer.

In the Still engine the jacket and cooling water form part of the circulating system of a steam generator, which may be an integral part of the engine, or external to it. The cooling water therefore enters and leaves the jacket at a constant temperature, regulated by the pressure of the steam, the cooling being effected by converting the water into steam without raising its temperature. Excluding the radiation losses, which are kept low by lagging, all the heat which passes through the walls is thus usefully recovered in the water as steam. The temperature of the cylinder wall is uniform over the whole of its exterior surface, and the heat lost to the cooling water at each stage of the cycle—compression, combustion and expansion—is diminished.

During compression, owing to the walls being at steam temperature, the incoming charge picks up heat, instead of losing it, during the greater part of the stroke, an advantage of the greatest value to the heavy oil types of Still engines, where an air charge is taken in at the full out-stroke, and is compressed to a pressure where its increased temperature ensures the certain ignition and combustion of the fuel which is injected into it.

During combustion and expansion, the uniform and higher mean temperature of the walls reduces the heat lost to the jacket water. Some of the heat thus economized adds to the useful work on the piston, the balance passing out in the exhaust gases for recovery.

Steam from Waste Heat.

After raising their quantum of steam, the exhaust gases are employed in preheating all the water required for the steam generated in the jacket water and in the generator. Trials at full efficiency over long periods and steady loads show terminal stack temperatures as low as 150° F. The heat efficiency of the combined cycles is therefore exceedingly good, with an initial temperature of over 2000° F., and a final exhaust to atmosphere at 150° F.

The quantity of steam capable of being generated from the "waste heat" depends upon the efficiency of the combustion cycle, and on the load. Years of experimental work have proved that the weight of steam recovered may vary from a maximum of about 7 lb. per b. hp-hr. developed by the combustion cycle of a four-stroke constant-volume engine, at full load, to a minimum at light loads which is hardly measurable and which only balances the loss due to radiation.

The steam recovered is a by-product, is limited in amount, its value depending upon the efficiency of its employment. This is carried out in a logical manner. Instead of being expanded in external auxiliary engines, with their thermal and mechanical losses, it is

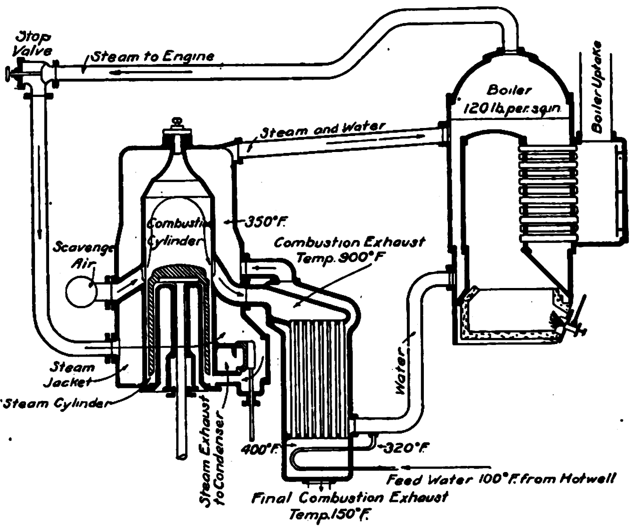


Fig. 1.—Schematic Diagram of the Still Engine.

returned to the combustion cylinders of the Still engine and is expanded on the opposite side of its main piston, one stroke being performed by steam and the other by combustion.

Among the results obtained it may be mentioned that (1) the mechanical efficiency of the whole engine is higher than that obtainable in a normal engine of similar type; (2) the steam, expanding as it does in a cylinder hotter than itself, gives an indicator diagram larger than that theoretically obtainable under ideal conditions in an ordinary steam engine; (3) 29% of additional brake-horsepower is added to the shaft of the engine, without increase in the fuel consumption (steam not condensed); (4) 40% is added with condenser used (air pump separately driven); (5) the initial horsepower due to steam appears as brake-horsepower added to the shaft, all the mechanical losses having already been accounted for in measuring the combustion brake-horsepower.

The average m.e.p. from the combustion stroke was 90 lb. per sq. in. The steam evaporated by the "waste heat" gave 14 lb. per sq. in. m.e.p. on every return stroke, equivalent to $90 + 28 = 118$ lb. per sq. in. m.e.p. in a normal four-stroke engine.

In trials carried on the frictional loss at 65° F. was nearly twice that when the jacket water was at 212° F., the maximum obtainable. In other trials carried on by Still the jacket water was maintained at a constant temperature of 320° F.

By admitting additional steam generated by fuel under the boiler, the steam m.e.p. was raised to 72 lb. per sq. in.: the total m.e.p. was, therefore, equal to $90 + 144 = 234$ lb. per sq. in. m.e.p. in a normal four-stroke engine.

The first experimental engine constructed was a two-stroke engine capable of developing 590 b.hp. from three cylinders at 400 revolutions, bore 8 in. It was a high speed engine, designed with special regard to obtaining data about the recovery of steam from waste heat in jacket and exhaust. It was first operated on town gas of 540 B.t.u. and subsequently converted for oil fuel. Its efficiency was not high, owing to its being a two-stroke engine with a short stroke, but its consumption per brake-horsepower was 15 cu. ft. per hour (31.3% efficiency), a very promising result.

The outbreak of war prevented much progress being made in the design and construction of gas engines, but the results achieved give great promise of

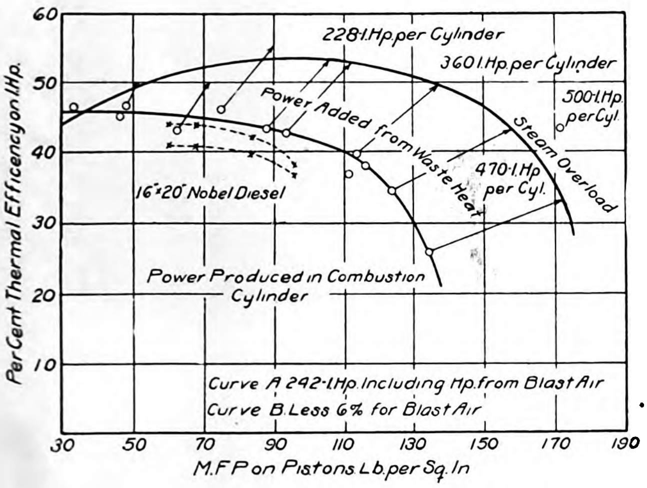

Fig. 2.—Diagram Showing Thermal Efficiency of 13.5 in. by 22 in. Still Engine of the Two-Stroke Opposed Piston Type. Shale Oil Used as Fuel.

future development, for with a combustion indicated efficiency of 36%, radiation 4%, boiler loss 10%, there remains 50% for recovery; allowing 10% efficiency for the steam cycle, a gain of 5% is assured, and the total indicated efficiency of the engine will not be less than 41%. If 20% efficiency is obtained from the steam cycle, as appears possible, the total indicated efficiency will be 46%.

A gas engine which can give a brake thermal efficiency 30% better than its predecessors and which, by governor control alone can meet any demand up to and over 100% overload, while maintaining a good efficiency at that increased output, cannot be neglected.

The Diesel engine relies for ignition solely on the temperature reached by compression of its air charge. On starting, this is carried out in a cold cylinder with a direct loss of heat to the walls during the whole of the compression stroke. A compression pressure of 500 lb. per sq. in. is necessitated to overcome this heat loss. This high pressure increases the cost of construction and upkeep, and, since the maximum explosion pressure capable of being reached in a closed vessel may reach six times the pressure contained in it, the whole design and weight of the engine is detrimentally affected. Its brake thermal efficiency of 30 to 32%, coupled with 20 years of intensive development in all lands, has, however, placed it at the head of all combustion engines in commercial operation using heavy oil fuels.

The Still oil engine starts with the cylinders and pistons preheated. The air charge, from the moment it enters into the cylinders, picks up heat from the containing walls and continues to do so during at least 70% of the compression stroke. The result is that the temperature necessary for firing with certainty the first injected charge of fuel is reached with a compression pressure 50% less than that required in a Diesel engine. This fact is far reaching in its importance, for it gives to the designer great elasticity and freedom of application, for a Still heavy oil engine can be designed for constant pressure or constant volume, or both can be employed in the same engine by correct timing of the fuel injection. It claims for its combustion cycle an efficiency higher than that of the Diesel, less weight and space per horsepower, and for its combined cycle an efficiency not less than 20% higher than any prime mover which uses fuel as its source of heat.

A unit of this type has been subjected to many long and varied tests by representatives of various governments, as well as to constant research work under severe conditions. Its best consumption of fuel (Admiralty shale oil) has been as low as 0.302 lb. per b.hp. (scavenge pump not included), over a test of one hour's duration under normal waste heat conditions. It developed 330 b.hp. for six hours at 360 r.p.m. (a single cylinder) under waste heat conditions. The thermal brake efficiency from below quarter load to full power is maintained at approximately 40% over the whole range.

Engines of this type operating at 120 r.p.m. with a cylinder 22 in. diameter by 36-in. stroke, giving 4200 s.hp. on two shafts, with all auxiliaries and water, would approximate 600 tons. A geared turbine plant in a similar ship would weigh 20% more and would consume approximately 2000 tons more fuel for a double journey lasting 1000 hours.

HARNESSING OF WATER POWER IN MEXICO TO GO AHEAD.

The Mexican government is planning to make a complete survey of all available water-power sites and to estimate the amount of energy which may be generated. Original concessions granted Americans and other foreigners were cancelled by the Carranza government.

Comparison of Mechanical Stokers

Classification of Mechanical Stokers—Salient Features of the Different Stokers — Influence of the Stoker Upon Draft, Combustion Chamber, Etc. — Part II.

By ROBERT JUNE

Mechanical Engineer.

AS HAS already been shown in the preceding articles, the advantages of the mechanical stoker over hand-firing are as follows:

1. Even and continuous firing of the automatic stoker, as compared to the intermittent action of hand-firing.
2. Practically constant and uniform supply of air which can be controlled to some extent to meet actual operating conditions, as contrasted with the wide variations in air supply occurring in hand-firing, with constant opening of fire doors, and varying depth of fuel bed.
3. Continuous and automatic cleaning of fires, leading to better over-all efficiency.
4. Large savings in labor, due to fact that one man can take care of 2000 hp. of stoker-fired boilers, as compared to 250 to 500 hp. of hand-fired.
5. Saving in fuel cost through ability to burn lower grades of coal than can be handled to good advantage with hand-firing.
6. Practical insurance of smokeless operation.

Overfeed Stokers.

Overfeed stokers are of two types—front-feed and side-feed. To the first type belong the Roney, Wilkinson and Acme stokers; to the second type, the Detroit, Murphy and Model.

With the front-feed stoker, the grate, which is arranged in a series of steps, slopes at a considerable downward angle from front to rear. Coal received from the hopper is coked under a short suspended arch and is then fed forward and downward by the rocking action of the movable grates, aided by gravity. The clinker working forward, is emitted at the bottom, being crushed by rolls in some types of installations. For convenience in handling, the dumping grate is frequently divided into several sections.

Front-feed stokers possess the important advantage of permitting easy passage of air through the fire so that complete and efficient combustion is readily secured. On the other hand, their combustion is such that if boilers must be continuously driven at high ratings, the grates may become overheated. In order to avoid this danger of burning, with possible necessary renewal of grates, engineers usually prefer other types of stokers, if it appears probable that boilers must be operated above 200% rating for considerable periods of time. Front-feed stokers used either natural or forced draft.

The side-feed or "V" stoker receives coal from two magazines, located on each side of what, to all intents and purposes, is a Dutch oven. At the bottom of the magazines are coking plates against which the grates, which are inclined at a steep angle toward the center of the furnace, rest at their upper ends. As the coal leaves the magazine, from which it is fed alternately and intermittently, it rests for a short time upon the coking plates. At this point the volatile gases are largely driven off, being mixed with air which has been pre-heated by admission through the arch over the fire.

As combustion proceeds, the fuel travels slowly down the inclined grate toward the clinker grinder, receiving the requisite amount of air through the grates to complete the process of combustion by the time the lower portion of the grates, where the ash and clinker are automatically removed.

The speed at which the stoker boxes push the coal into the grates is of course subject to easy regulation. The grates, being protected at their upper ends and actuated at their lower ends, agitate the fuel bed to a constantly increasing extent as combustion proceeds, thus permitting free admission of air and assuring complete combustion. In stokers of this type the clinker grinder can be adjusted to operate with reference to the amount of ash and clinker in the coal, irrespective of the action of other parts of the mechanism.

For boilers of moderate size, operated at 200%

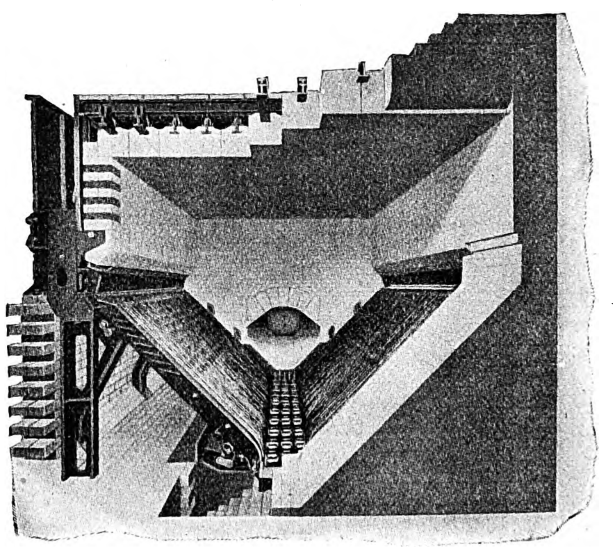

Fig. 1.—Overfeed Type of Stoker.

rating or less, the side-feed stoker makes a desirable and economical installation. It has the advantage of possessing a decidedly larger coking area than other types of stokers, and as its combustion area is likewise very large, it is possible, with careful manipulation, to secure complete and practically smokeless operation. Natural draft is the rule with this stoker.

The Down-Draft Furnace.

While the down-draft furnace is not to be strictly classed as a stoker, since its use involves hand-firing, it nevertheless deserves consideration, since it performs certain of the functions of the mechanical stoker; that is to say, as compared to ordinary hand-firing, it permits the use of lower grades of fuel, assures practically complete combustion, and what is extremely important in many installations, smokeless combustion.

The down-draft furnace consists of two separate grates, one above the other, the upper grate being formed of a series of tubes, opening at their ends into steel drums or manifolds, through which the water of

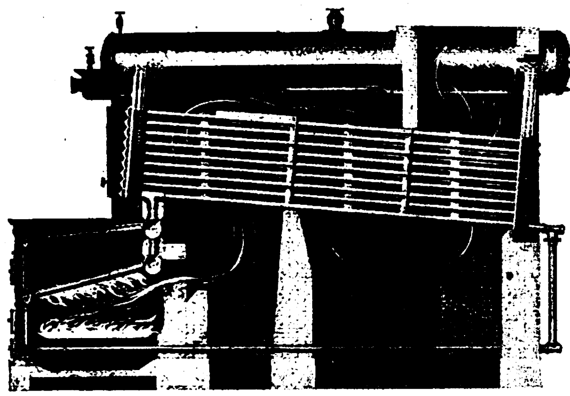

Fig. 2.—Down-draft Type of Stoker.

the boiler circulates, whereas the lower grate is formed of ordinary grate bars. The firing doors are near the top of the furnace and the upper grate only is fired. This grate, it should be noted, slopes upward at a sufficient angle to assure rapid circulation.

A division wall at the back of the furnace prevents the gases from going rearward, hence the draft is downward through the fuel bed, and the volatile matter, as it is evolved, passes directly between the grates into the combustion chamber. The lower grate is fired entirely by coked coal falling through the tubes of the upper grates. As the flames from the lower grate arise, they meet the down-coming gases and the process of combustion is completed.

An objection sometimes raised to the down-draft furnace is that it "cannot be forced above rating," but this is not strictly true as it can be driven to nearly if not fully the same extent as a hand-fired furnace. When installed under conditions within its limitations, it is more economical and satisfactory than hand-firing.

The Under-Feed Stoker.

Among the best-known underfeed stokers are the Taylor, Westinghouse, Type "E," Riley, Jones and American.

The under-feed stoker is the stoker for large installations and exceedingly high ratings. Indeed, so completely has it pre-empted this field that it is unusual to go into a large central station or high-duty large boiler power plant of any sort, built within recent years, and find other types of stokers installed.

There are a number of reasons for this. First of all, the under-feed stoker is adapted to all grades and sizes of free-burning bituminous coal. Next, it is essentially a forced-draft stoker since it operates with restricted air openings, and very deep fires. The forcing capacity is almost unlimited, instances being known where this stoker has been driven to over 400% rating.

Sufficient combustion-chamber space is the principal consideration in making under-feed stoker installations, as with this stoker it is necessary to elevate the boiler a very considerable distance above the floor. Coking arches or plates are dispensed with entirely. The principle of the under-feed stoker is that of a steam-driven ram, which forces the fresh coal into a large receiving retort, contained within the furnace, and from there up under the fuel bed.

The Jones stoker consists of nothing whatever except this retort, or a series of retorts, depending upon the size of the boiler. There are no grate bars and no ashpit, just a blazing pile of coal, continually fed with new supplies pushed up from below. Air is admitted through hollow blast tiles at the upper edges of the retort. Ash and clinker form chiefly on the dead plate between the retorts and are removed by hand at intervals of a few hours. Automatic control of air and fuel supply is secured, definite proportions of each being admitted as the steam pressure tends to rise or fall.

In the Type "E" stoker the retort has a reciprocating sliding bottom which carries the coal forward. It is delivered uniformly from front to rear by auxiliary pushers, and as it rises in the retort, is distributed to the sides of the furnace by means of rocker bars, so set as to slope both ways from the center of the furnace toward the side walls. The progress of the burning fuel and also of the ash and clinker is thus from the center to the sides of the furnace. As the action of the rocker bars is slightly up and down, clinker is kept from forming in large pieces. Dump trays at the side permit cleaning by the act of throwing a single lever.

More elaborate than other underfeed stokers, the Taylor consists of a series of alternate retorts and tuyeres, sharply inclined toward the rear of the furnace. Each retort is fitted with two rams—the upper for pushing the green fuel inward and upward, the lower for forcing the fire toward the dump plates at

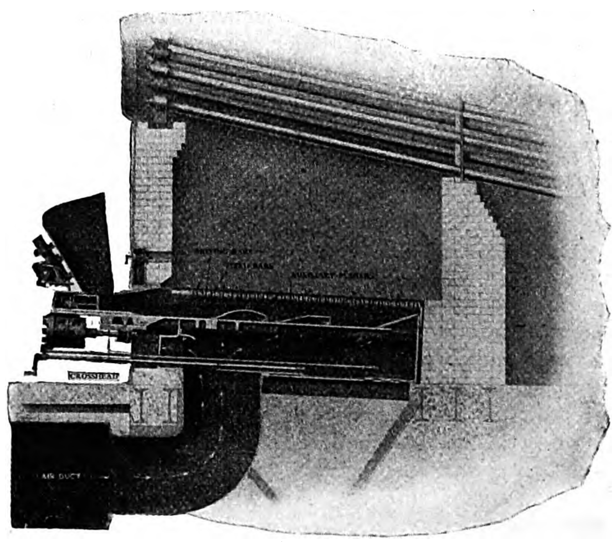

Fig. 3.—Underfeed Type of Stoker.

the rear. The dump plates referred to are hung on the rear of the wind-box. They are controlled from the front of the furnace. This stoker may be operated efficiently and smokelessly at the heaviest known overloads, hence it is frequently found in the largest plants. Stoker and blower are operated by the same engine and power required for this purpose is from 2.5 to 5% of steam generated, making it probably the highest steam user among the stokers.

The Riley is a multiple-retort stoker, the distinctive feature of which is that the sides of the retort reciprocate relative to the bottom. This arrangement results in the fuel being moved at a uniform rate out of the retort and across the ash supporting plates

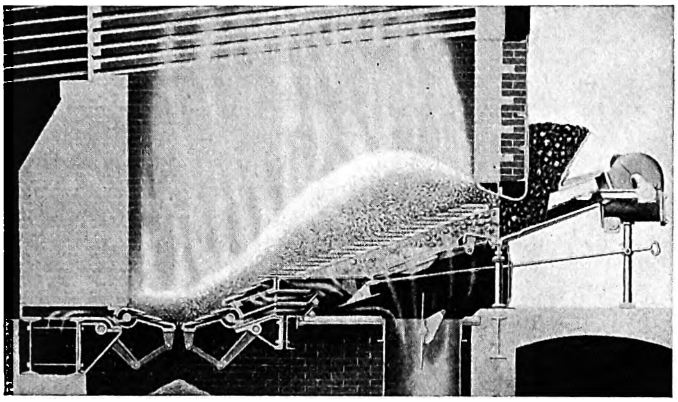

Fig. 4.—Cross-Section Showing Fuel Bed With Underfeed Stoker.

until it is discharged through adjustable openings next to the bridge wall.

Points to Remember Regarding Stoker Operation.

The following are a few of the points to remember regarding stoker operation.

1. Draft must be under close control at all times.
2. Keep air vents open.
3. Look out for air leaks, particularly after making adjustment.
4. Make frequent flue-gas analyses.
5. Keep side walls clean of adhesions.
6. Do not stop stoker long with hopper full of coal.
7. In chain grates make adjustment of gate and speed if fire tends to withdraw from gate or run over end
8. Coking coal may require slice bar.
9. In washing out boiler, do not get water on arches or brickwork.
10. Do not pull dead plates entirely clear of ash.
11. Keep ash-pit cleared out.
12. Have all necessary maintenance work attended to promptly.

Summary.

It has been shown that the chain-grate stoker is suitable for boilers of good size up to 250% and that its important characteristic is that the grates must be designed for the fuel burned. It has been shown that the overfeed stoker is particularly suitable for medium sized installations up to 200% rating. The down-draft furnace, particularly for small boilers operated at non-excessive ratings, offers a comparatively inexpensive substitute for certain functions of the mechanical stokers. And, finally, the underfeed stoker has been placed as the apparatus for large boilers, operated at extremely high ratings.

TRANSFER OF GUATEMALAN ELECTRIC PLANT TO AMERICAN COMPANY.

German Plant Taken by Government and Leased to American Interests—Extensions Proposed.

The electric lighting and power plant of Guatemala City (Empresa Electrica de Guatemala) was granted a 30-year concession some 25 years ago for electric lighting and power service in the city of Guatemala. The enterprise has always been a German institution, and more than 90% of the stock was held by the Deutsche Bank of Berlin. By executive decree No. 742 of October 16, 1918, this property was taken over by the Guatemala Alien Property Custodian and by later decree was declared forfeited to the Guatemala Government and nationalized. By executive order this property has now been leased to Henry W. Catlin, No. 71 Broadway, New York, for the term of 10 years, at a cash rental of $40,000 per annum, together with the option of extending the lease for an additional like period. The Government concession under which the old company operated has been extended for the life of the contract and any prorogation. The lessee also becomes the preferred bidder in any future sale of the property.

The plant was erected by the Siemens-Halske Co. (Berlin), and is hydroelectric, with a present capacity of 2000 kw. at 4000 volts three phase alternating current, which is transmitted from the power station at Palin, 28 miles distant from Guatemala City. This is reduced at the local station to 1000 volts for primary distribution over the city. The house service is 120 volts. The entire pole line, both transmission line and for city distribution, is made of 9 and 10-in. I-beams. Some 16,000 incandescent lamps, 280 open arc street lamps, and 2000 hp. in motors are served.

Before the earthquakes of 1917-18 about 30,000 incandescent lamps were connected.

The leasing company also acquires the right to an incompleted additional water power and central station at San Luis, about 6 miles from Palin, the present operating station which, when completed, will give an additional 3000 kw. This additional power will probably be completed promptly by the leasing company, as there is much demand for additional light and power service in that city. It is a common thing to see advertisements of electric motors for sale, "with right of electric service," and at the offices of the company are many applications for power awaiting their turn. The plant as it stands today has an estimated valuation of $1,000,000, and the cost of completing the auxiliary station is estimated to be in the neighborhood of $300,000.

IMPROVEMENTS IN POWER PLANT AT ST. JOSEPH, MO.

New Condensing Turbo Unit—Oil-Burning Equipment—Other Rehabilitation of the Plant.

Improvements in the plant of the St. Joseph Street Railway, Light, Heat & Power Co., St. Joseph, Mo., which will amount to approximately $1,000,000, have been started. Excavations are now completed. The improvements are to include a 12,500-kv-a. turbine-generator complete with surface condensers and auxiliary switchboard equipment. This new unit alone is able to take care of all of the city's present requirements and 20% additional, which includes both light and power and leaves the entire old installation to take care of further increases in the future. Workmen are relocating two 440-hp. boilers and are installing two additional boilers of 1000 hp. each. A complete new arrangement of boiler-feed pumps and accessories will be made. A complete oil-burning system will be installed throughout the plant, which will do away with coal entirely. This includes a 30,000-barrel fuel-oil storage tank, with 800 ft. of track for the supply of oil. Two new steel stacks will be constructed, one 16 by 225 ft. and the other 12 by 225 ft.

NEW PLANT FOR MANUFACTURING RADIO APPARATUS.

Brief Description of the New Kilbourne & Clark Factory at Seattle, Wash.—Motor Drive Throughout.

By W. A. Scott.

A brief outline of the new factory of the Kilbourne & Clark Manufacturing Co., of Seattle, Wash., will be of interest because in it there are exemplified the most advanced facilities for constructing and testing radio apparatus, and because of the world-wide demand for the company's products. Wireless equipment of the Kilbourne & Clark design, which was developed a few years ago, won its way to favor almost at the beginning, with none to challenge its efficiency. During the war its production was increased with great rapidity to keep pace with the tremendous demand for radio apparatus for new ships of war and commerce, and to supply the facilities for operating wireless stations on land, both in the United States and in allied and neutral countries.

This strictly American industry, to which great impetus was given because its product was a war essential, found at the close of the war that a national and international demand had developed for its apparatus.

The new plant at Seattle, designed and equipped to meet the requirements of this specialized industry, was completed and put in operation within the last three months. The building made up of four interconnected structures, is well shown in one of the illustrations presented herewith. It is constructed of reinforced-concrete walls, and wooden floors laid upon concrete slabs, with roofs of saw-tooth type to afford the best possible daylight and ventilation; the roofs are of mill construction, a part of the framework being supported by timber columns.

The main shop building, an interior view of which is given, is 100 ft. wide and 300 ft. long, having a 24-ft. ceiling. The lengthwise direction of this shop structure is north-south.

The three wings built at right angles to it extend easterly toward Whatcom avenue on which the plant fronts. The center wing, as is shown in the illustration, constitutes the office building, which is 60 by 60 ft. The south wing, 60 by 100 ft., is the laboratory and engineering building; and the north wing, 60 by 100 ft., is the stock and storage building. By referring to the exterior illustration it will be noted that there are parkings in front of and on both sides of the office building, and that the north and south wings come out flush to the sidewalk adjoining the paved street.

Electricity for Motive Power and Testing.

Electricity is utilized for all power requirements and testing operations. Energy is supplied from two outdoor 100-kv-a. transformers at the rear of the main shop building, being transmitted at 220 volts through lead-sheathed overhead cables to the main switching panels in the shop. The power load is not a heavy one, as most of the driven machines and tools are for comparatively light work in which precision and speed are the essential requirements.

The 43 Wagner motors installed are practically all alternating current, operating at 220 volts at different speeds, although there are no variable-speed motors.

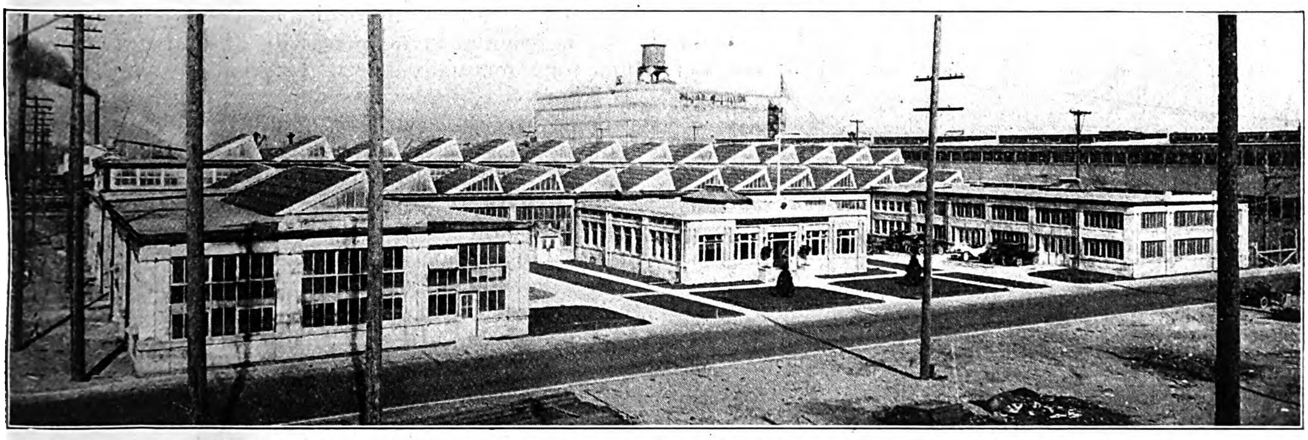
It will be observed, by reference to the interior view of the main shop, that the most of the lathes, drills and milling machines are operated in groups by motors hung from the ceiling. These motors are of 5-hp. and 10-hp. capacities, leather belts being used for transmitting power from the motors to line shafts and for connecting the latter to the tools and machines. There are, however, a number of lathes and other tools of the heavier class which are driven by 10-hp. and 15-hp. individual motors, each set upon the floor and connected to the driven machine by a short leather belt. Some of the heavier tools thus operated consist of a Cleveland automatic lathe, and three Revette lathes.

An interesting feature of the shop work is seen in the tool-making department, where motors of light capacity and high speed, with leather-belt transmission, are required in driving special machines in groups. Here precision tools and devices are made which are adapted to the work in manufacturing wireless apparatus.

In the speedy production of parts required in assembling radio equipment there is maintained a systematic routing of work through the factory, and the mechanical and electrical installations were arranged with that system in view. The thorough inspection methods established are applied to all stages of the manufacturing.

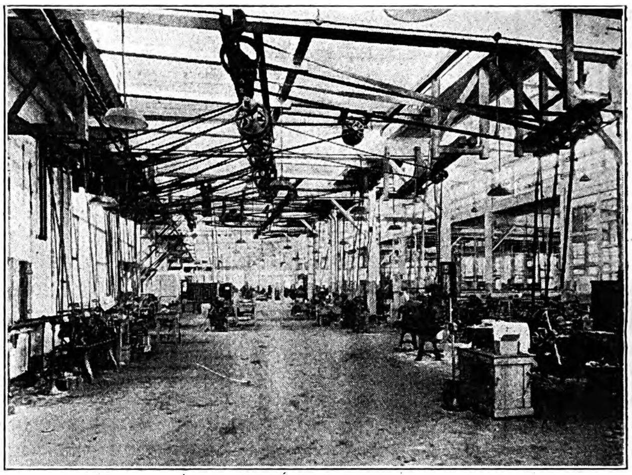
The raw materials used in wireless apparatus consist of steel, brass, copper, aluminum, and insulating material, the last named consisting chiefly of Bakelite-Dilecto, a trade name for a special kind of condensation product of excellent insulating and mechanical properties.

The laboratory is equipped with the latest types of



General View of the New Plant of the Kilbourne & Clark Manufacturing Co. at Seattle, Wash. In Plan View the Buildings Form a Large Letter E.

View of Part of the Laboratory and Testing Department for Development and Testing of Radio Apparatus.



Interior View of the Main Shop Building of Kilbourne & Clark Plant.

instruments and appliances for testing out radio apparatus before shipments or deliveries are made. Many standard and special instruments are also required in research work. As direct-current energy is required in testing part of the apparatus, a 25-kw. motor-generator set was installed in a compartment adjoining the laboratory and testing room, to convert alternating to direct current. This consists of a Wagner motor and a Westinghouse generator. In one of the illustrations is given a view of the laboratory and testing department.

An engineering organization is maintained, not only to make inspections and tests, but to conduct research work and to produce new and improved designs along the lines of the radiotelegraphic development. In this connection there is operated an electrical blue-printing and drying department for the rapid production of shop drawings.

Illuminating Facilities.

The buildings are wired throughout in conduit, providing outlets for high-intensity, glare-free general lighting. The main shop building is illuminated by 110 of the 200 and 400-watt Mazda C lamps, spaced 12 ft. apart, and equipped with Ivanhoe Reflecto-Cap units. The laboratory is served by 100-watt lamps and reflectors of similar type, while the offices are illuminated by 150-watt Mazda C lamps in Perfeclite semi-direct fixtures. Other parts of the plant are lighted by 100-watt units with steel dome reflectors. but without diffuser caps. Except in a few special cases no local lamps are required for machines and tools.

Provision is made for an electric overhead crane of 31-ft. span in the main shop, but which has not yet been installed.

THE AUTOMATIC SUBSTATION FROM AN ECONOMIC STANDPOINT.

How Electric Railways with Light Traffic Can Save Money by Installing Attendantless Substations.

The tendency in the development of modern electrical apparatus is to utilize more and more the automatic features which are proving to be important factors in extending its use. Probably no recent development has created more general interest or possesses more economic possibilities than that of the automatic substation for electric railways, especially interurban.

The automatic substation usually consists of a synchronous converter, a bank of transformers and three or four switchboard panels, on which are mounted electrically operated switches, relays and instruments. It is really almost uncanny in what it will do when the trolley voltage falls below a predetermined safe value. Without human aid the converter starts up and reaches synchronism and assumes its share of the total load on the line. If the load increases to a point dangerous to the converter, it immediately shuts itself down and the line switches all open. If a converter bearing should overheat, instantly a relay operates and the converter shuts itself down. If the load on the line drops to a point where the converter is not required, it automatically comes to rest. It will go through this cycle of starting and stopping just as often as the line conditions make it necessary, it being possible to start up, close all switches, open all switches and stop the converter twice per minute.

Naturally, since such power is at instant call without an attendant at the station certain limitations exist which react to counterbalance the good qualities of automatic switching but they in no way destroy the great commercial advantages of such switching.

A competent engineer must inspect the apparatus weekly and the station must be cleaned up three or four times a month. One engineer could inspect a great many stations on a regular schedule, so this item will add but a trifling labor charge. The cleaning up can be done by ordinary car-barn labor.

The original investment will, of course, be greater than for a manually operated station of equal capacity.

There may be increased hazard to the equipment, although results thus far obtained indicate that the equipment is better protected by automatic switching than by hand switching.

Automatic switching is more complicated than hand switching, but on close acquaintance it becomes quite simple.

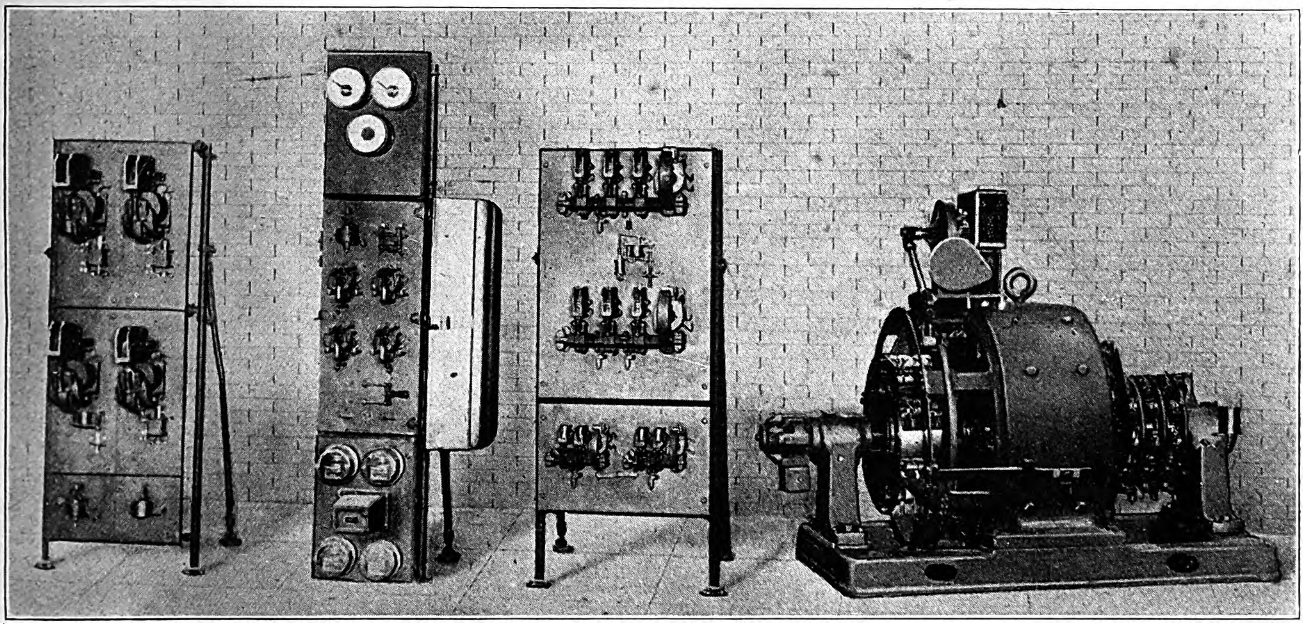
Feeders must be applied with great care to save trolley wires which drop to the ground from annealing.

Since there are no operators to transfer high-tension lines in case of trouble these lines may in certain cases have to be arranged for automatic installations. It may be possible to handle this high-tension switching by remote control.

The economic features which offset the foregoing disadvantages are so great that they leave a heavy balance in favor of the automatic switching. The fact that automatic substations require no attendants should itself effect an economy of $2500 per station, allowing two men per station for hand switching. The absence of attendants leads directly to a second marked advantage, the elimination of labor difficulties. This is an important factor under the present disturbed condition of labor generally and the uncertainties of the future.

Since the automatic station shuts itself down when power is not required, the saving in energy will amount to a considerable item. No-load losses are thus eliminated, which is particularly advantageous on interurban lines where the power requirements are intermittent.

There is also a reduction in feeder loss as the substation can be located exactly where needed without reference to labor operating cost. By relocating or increasing the number of substations enough feeder copper can be saved on many propositions to pay for a great proportion of the cost of automatic switching.



Typical Automatic Substation for an Interurban or Other Light Electric Railway.

There is invariably a reduction of electrolysis due to absolutely correct location of automatic stations, thus reducing the return circuit in length and in losses due to drop.

Experience thus far indicates that reliability of operation will be increased. Considering the ability of the best operators that can be secured and the introduction of the ever varying "human element," the automatic switching should prove by far the more reliable method of operation.

Maintenance has been very low in those cases which have been under operation. This charge will drop exactly in the proportion, that inspection and cleaning of apparatus is kept up and with experience will doubtless drop to a very low value.

Summing up, there is do doubt but what the automatic substation is here to stay and its economic features demand consideration whenever the installation of a new substation is projected. The following table shows typical economies from such an automatic substation:

TYPICAL ECONOMIES OF AUTOMATIC SUBSTATIONS.

Headway between cars	Hours	1	2
Length of line	Miles	25	25
Number of substations		3	3
Capacity of substations	Kw.	300	300
Distance between substations	Miles	10	10
Schedule speed	M.p.h.	25	25
Length of operating day	Hours	20	20
Total substation hours (manual operation)	Hours	60	60
Total substation hours (automatic operation)	Hours	32	20
Running-light loss per station	Kw.	15	15
Energy saved per day (automatic operation)	Kw-hr.	240	600
Energy saved per year (automatic operation)	Kw-hr.	153,300	219,000
Value of energy saving at 1 cent per kw.-hr.		$1,533	$2,190
Labor saving per year (6 operators at $70 per month)		$5,040	$5,040
Total saving per year		$6,673	$7,230
Total investment automatic control—3 stations		$1,800	$1,800
Interest, insurance, maintenance, depreciation, taxes—15%		$2,700	$2,700
Cost of inspection per year		$ 500	$ 500
Total annual charges		$3,200	$3,200
Net annual saving		$3,373	$4,030
Return on investment, per cent		18.7	22.4

CUSTOMER OWNERS HELP SAVE PLANT.

Recently the Minnesota Valley hydro plant of the Northern States Power Co. experienced the highest stage of water on record. Nearly five feet of water was spilling over the dam and the tail water rose to 19 feet, flowing into the plant through the windows and doors. C. D. Hunt, manager of the Southwest Division of the company, reports the following as to what transpired:

"The farmers living in the vicinity of the plant came to our rescue at midnight and faithfully manned the pumps for 48 hours until other means could be employed to lower the water in the generating room of the old part of the plant. It is significant that nine of the farmers who came to our rescue were stockholders in the company. These farmers left their work for 48 hours to assist in the work of saving the plant."

COAL SAVING DUE TO DAYLIGHT SAVING.

During the daylight saving season last year, the Edison Electric Illuminating Co. of Boston saved 4420 long tons of coal because of the extra hour of daylight utilized by turning the clock one hour forward. The decrease in kilowatt-hours from this cause was 5,000,000, representing a loss of revenue of about $350,000.

Editorial Comment

Daylight Saving to Stay

PRESIDENT WILSON'S veto of the Congressional attempt to repeal daylight saving and the failure of the House to pass the measure over his veto settles the fate of this summer-time practice probably for another year. The only avowed opponents of the practice are the farmers who must engage help to work their fields. Apparently they are an influential lot, for they quite readily awed Congress to meet their wishes. We are convinced, however, that the great majority of the country's citizenship is heartily in favor of daylight saving every summer. Electric lighting companies are sufferers from it, but almost without exception they are glad to bow to what is manifestly for the public good.

Machinery Must Replace Emigrants

NOW that peace is here, swarms of aliens are leaving this hospitable land and going back to their native abodes with their pockets swollen with American money earned during their profitable sojourn among us. The great majority of these emigrants have not assimilated our ideas or customs or even our language. Their departure is therefore in one respect no serious loss to our country. But it is a substantial loss to our labor supply. To what extent immigration will replace emigration is very uncertain. There is one certainty, however. It is that machinery will have to be called on more and more to do work that is now done manually, so that the remaining labor will be more effectively applied. Increased use of machinery means more electric motors for driving it and more electric power for keeping the motors running. The electrical industry is ready to do its part in this case just as it has done in relieving the emergency in household work since servants became scarce.

Higher License Fees for Contractors

CHICAGO'S proposed new ordinance governing the licensing of electrical contractors which is reviewed elsewhere in this issue may at first appear to be a rather stiff and expensive proposition calling for a needless outlay which must be borne by the electrical contractor. However, when the conditions existing are understood it surely seems justified. There are at present many journeymen carrying licenses while working for legitimate contractors who compete with their employers for work. In addition, there are many others, such as the maintenance men in large plants who carry on a lively contracting business in the evening and during their other spare hours.

In view of these facts, therefore, it is not surprising that the contractors themselves favor the ordinance and wish to see it become a law. The classifying of licenses is another good feature of the proposed ordinance, for there is no reason why a manufacturer who only has repairs and alterations made in his own equipment should pay the same license fee as the general contractor who does all kinds of electrical work.

A Highly Efficient Engine

ON other pages of this issue are given some of the principal features of the recently developed Still engine, which has aroused a great deal of attention in Great Britain. This unique prime mover deserves as much attention in other countries. Its most important feature is the very high thermal efficiency attained, this being 40% or over. An indicated thermal efficiency of as high as 46% seems probable in future developments of this engine. These high efficiencies are obtained through the combination design of this unit.

Primarily it is an internal-combustion engine whose cylinder-cooling water is kept practically at or just above the boiling point, the steam thus formed being used either in another cylinder or on the other side of the main cylinder to help develop power. Thus the water carries away the heat and utilizes it effectively instead of wasting it as usual. The heat in the exhaust gases is used to preheat the circulating water, so that the gases are discharged at as low as 150° F. Although the engine does not seem to be a very simple one in construction it has very promising possibilities and we expect to see it outdistance the Diesel engine at least.

Keep Food Prices From Soaring

FURTHER increases in the prices of many foodstuffs are offered as the excuse for demands for further wage increases, for increased prices for a variety of commodities and for a reluctance to buy necessities. The net result is a check to the steady expansion of business. Advanced prices in one line react on other lines and there is produced a seemingly endless cycle of continued advances. This is not wholesome to business or industry nor to the country as a whole. A check must be put to it.

Since food prices receive the principal blame, let this be the line to be prevented from further inflation. In view of the fact that food supplies and food distribution will remain abnormal for about a year on account of the inability of Europe to get squarely back on its feet before that time, all attempts at profiteering in foods, cornering of food supplies and unscrupulous speculation in this line should be dealt with as vigorously as they are being treated in France and Italy. Public utility service is firmly under public control. Is food less essential, so that it should not be controlled? Stop the food profiteer, so as to stabilize wages and prices of commodities and thus permit commerce, industry and labor to supply the wants of the world.

Electric Lighting Needed Still More in Summer Resorts

VACATION time is here with its hegira of city folks to the country, seashore and mountains. The hot and sweltering city is gladly left behind for the pleasure of the big outdoors and the relaxation of simple, rural life. And after a few days of this simple life some of its shortcomings force themselves on the average city person who dislikes to do without the more essential conveniences of modern urban life. If the resort at which he is stopping is one of those that were almost universal up to a few years ago, he misses electric lighting probably more than any other utility to which he is accustomed.

The reason for this is obvious. Electric light is the most safe and convenient kind of illumination. Oil lamps, acetylene or gasoline lights are far from being its equivalent. They are very hazardous under any conditions and especially so in the wooden buildings still so very common in summer resorts, even among the more expensive ones. Electric lighting permits dispensing entirely with matches, a fruitful source of disastrous fires. The competing types of lighting mentioned above are also by no means as convenient, comfortable or healthful, especially on a very hot or sultry evening.

In the last few years considerable headway has been made in providing electric lighting in summer hotels and cottages. Where resorts are quite close together they are now frequently served from the lines of some neighboring central station. In other cases where a number of hotels or private houses are clustered into a small community that is itself remote from any regularly established central station or transmission line, it has become the practice to install a self-contained lighting plant of such size as to serve the community. In still more cases of isolated resorts it has become quite common to put in a lighting plant of the farm-lighting type with storage battery to carry the load of the late night hours.

These installations of electric lighting in summer resorts, whether they be any of the types referred to or modifications thereof, are proving to be very popular, especially if their capacity is large enough to also permit the use of small portable appliances, such as hair curlers, fans for very hot nights, travelers' flat-irons for pressing ladies' dress accessories, etc. There is much room for installation of more of these electric lighting systems in the resorts that are still trying to get along with other methods of lighting that are not only obsolete but seriously endanger the lives of their guests.

Real Co-operation in the Electrical Industry at Last

CO-OPERATION, such as has been long desired and talked about as a necessary adjunct to the electrical industry, was demonstrated for the first time in a national way at a conference called by the Executive Committee of the National Association of Electrical Contractors and Dealers in Milwaukee on Monday of this week. On this occasion the various branches of the industry were called together to discuss and develop the Bureau of Education and Research which has been organized by this association. In addition to the representatives of this association there were present the authorized representatives of the Associated Manufacturers of Electrical Supplies, the Electrical Supply Jobbers' Association and the National Electric Light Association and the electrical press.

The picture presented by these men gathered together to discuss a national proposition of vital importance is surely evidence that the co-operation idea has at last taken root in our industry. Nor did they gather merely to discuss co-operation, as is generally the case, but for the purpose of developing and starting a co-operative effort for putting real co-operation into effect.

The Bureau of Education and Research is an elaborate and extensive plan for promoting the sale and use of electric apparatus. The idea of the plan, as explained in an earlier issue of the ELECTRICAL REVIEW, consists of an educational campaign to be carried on among the contractor-dealers of the country by which it is expected to materially increase the sale of electrical appliances and improve the conditions among the trade. However, in order to accomplish its purpose a fund had to be established which the contractor-dealers' association was not able to finance from among its own members. Its officers, therefore, called upon the other branches of the industry for assistance which resulted in the conference.

After considerable discussion a fair and equitable plan was devised by which all branches of the industry contribute to the support of the movement. The expense of the national work is to be borne by the manufacturers of electrical appliances in proportion to the amount of sales obtained through the efforts of the members of the National Association of Electrical Contractors and Dealers. The expense of the local propaganda is to be borne by the local jobbers, the central stations and the larger contractor-dealers in like proportion.

Aside from the importance of this plan, however, the principal feature is that for the first time in its history all the branches of the electrical industry got together on a national proposition, thrashed it out on an equitable basis and really did co-operate. For this reason, especially, it is hoped that the plan will prove a tremendous success and encourage future activities along similar lines.

Big Electrical Conventions at Milwaukee and Cedar Point —Electric Railway Investigation Bringing Out Real Facts

WORK ACCOMPLISHED FEATURE OF CONTRACTORS' NATIONAL CONVENTION.

Great Enthusiasm Displayed by Members at Opening Session in Milwaukee on Wednesday.

A very striking feature of the opening session of the annual convention of the National Association of Electrical Contractors and Dealers, which was held at Milwaukee on July 16 to 18, was the large amount of work that has been accomplished by the association during the past year and which has been developed to a point where it can be put into effect during the ensuing year. Although the association has been organized for many years, several radical organization changes were made in it during the past two years, the development of which was greatly restricted by the prevailing conditions during the war. However, since the armistice was signed the association has been actively engaged along many lines for the benefit of its membership and the amount of work which it has accomplished is truly remarkable.

The energy and enthusiasm of the members present was evidenced by the lively discussions which took place after each address during the opening sessions and which it is seemed would take place during the remainder of the convention. Over 400 members registered from all parts of the country and, in addition, there were a very large number of representatives of electrical manufacturers, supply jobbers and other electrical interests present who took an active part in the proceedings.

The meeting was opened by P. C. Burrill of the Herman Andrae Co., of Milwaukee, chairman of the Wisconsin State Association of Electrical Contractors and Dealers. In his address Mr. Burrill described the industrial conditions which exist in this country at the present time and which create a great demand for the services of the electrical contractor-dealer. The contractor, however, must do his best to serve the public if he is to reap the benefits of this opportunity.

Mr. Burrill then turned the chair over to W. Creighton Peet, of New York City, chairman of the National Association, who introduced Cornelius Corcoran, acting mayor of Milwaukee. Mr. Corcoran in his welcoming address to the assembled members dwelt upon the features of that city and also upon the patriotism which its citizens had demonstrated during the war. He urged those present as business men to take a more active part in the political affairs of their communities and stated that this was the best means of improving local conditions.

Mr. Peet, in reply to Mr. Corcoran's address, described the work which has been done and which is being done by the National Association. Among the principal features of this work is the Bureau of Education and Research, which has now been fully worked out and which will be put into operation in a very short time. Another feature is an agreement which has been practically completed with the Morris Plan Banks through which the members of the association can secure the necessary financial aid to enable them to sell appliances and wiring on part-payment plans. In addition, the Architects' Committee, the Code Committee and the Insurance Committee have also been particularly active.

During the past year, Mr. Peet stated, the membership of the National Association has been increased 35%, which is the largest increase ever made in one year by the association. This was accomplished in spite of the very unsatisfactory conditions that existed in construction work during this time. However, in order for the association to accomplish the best results it is very desirable not alone that this increase be maintained for the next year, but that a much more rapid increase be made. Mr. Peet also urged the members to read their electrical trade journals more fully and explained that it is only by such means that the electrical contractor-dealer can keep up with the times. In closing, he requested the members to lend their support, and when called upon to perform any services by them they should do so willingly and to the best of their ability.

Franz Nielsen, attorney for the National Association, then spoke on co-operation in business. Mr. Nielsen was at a decided disadvantage on account of having had practically no notice that he was going to talk. His address, however, proved to be very interesting and brought out a number of points on the co-operation idea which should prove of value to the members. He described the growth of the co-operation idea in business and the remarkable position which it holds in the business world today. He also pointed out the fact that without the earnest support of its members no association can succeed and urged the members not to wait until called upon to assist in the conduct of the association's work but to come forward of their own volition and offer their services.

The first speaker at the afternoon session was Frank Stockdale, of Chicago, who spoke on "Keeping Up with the Rising Costs," with particular reference to merchandising. He explained that a large number of merchants do not give the proper consideration to profit and for this reason a large number of them fail. In his opinion the electrical contractor-dealer up to the present time had just been nibbling around the edges of the possible total amount of business. One of the reasons for this is the fact that the electrical dealer has entered the merchandising field from the mechanical side. While this fact unquestionably gives him a better knowledge of the goods that he handles, it does not materially assist him to become a successful merchant. He pointed out that the electrical contractor-dealer's problems cannot be solved by deciding what the other fellow should do but by what they do themselves. The successful merchant, he stated, should be a buyer, seller (which includes displaying, advertising and personal salesmanship), accountant, the manager of his store and its people. It is a difficult matter for one man to be successful in the first two qualifications especially, since their requirements conflict somewhat.

Merchandise, he stated, should be bought in cold blood and sold with enthusiasm. Too often the opposite conditions prevail and the merchant buys material without giving a thought as to how he is going to get rid of it. He pointed out the advantage which the electrical dealer has over other dealers in displaying his wares. Electrical merchandise from its nature contains the three fundamental attributes of good window displays—color, novelty and action. In spite of this, the average electrical contractor-dealer's show windows are not very attractive. The show window, he explained, is the face of the store and from it the public gets its impression of the store and the merchant. For this reason the merchant should try to keep his show windows as clean and attractive as possible.

He also spoke of the new accounting system which has been developed by the association and stated that in his opinion it was one of the best and simplest he had ever seen. He also briefly explained the cardinal principles of this system. In closing, he pointed out that a merchant gets paid exactly for the kind of work done and if he allows himself to be wrapped up in the details of his business he will never get very far. At the close of Mr. Stockdale's address a lively discussion ensued, during which several interesting facts relative to electrical merchandising were clearly brought out.

Albert Uhl, of Chicago, president of the Chicago Electrical Estimators' Association, then explained the new estimating forms which have been developed by this association. These forms provide a method of figuring an estimate and keeping record of it in an accurate and convenient form. Mr. Uhl's talk was suitably illustrated with lantern slides. E. L. Morley, treasurer of the same association, then described its overhead cost curve, which was described in a previous issue of the ELECTRICAL REVIEW, and a new set of electrical symbols which has been developed by the Chicago Electrical Estimators' Association for use on building plans. The value of the work which has been done by this association and the interest which the members who were present took in it was probably best evidenced by the discussion which followed Messrs. Uhl's and Morley's addresses.

A full report of the remaining proceedings of the association's convention will be given in our next issue.

OHIO ELECTRIC LIGHT ASSOCIATION HOLDS BIGGEST CONVENTION.

Twenty-fifth Annual Meeting, July 15 to 18, the Most Important Held by Organization—Many Vital Problems Discussed.

The twenty-fifth or silver anniversary convention of the Ohio Electric Iight Association, which was held at the Breakers Hotel, Cedar Point, Ohio, on Tuesday to Friday of this week, was declared by all to be the largest gathering in the history of the association. The initial registration was about 550. All of the meetings were largely attended and keen interest was taken in all of the papers, reports and addresses presented; this was shown by the active discussion which followed nearly every topic as it was presented.

The first session on Tuesday morning was opened by the presidential address of I. L. Oppenheimer, of Pomeroy, Ohio, who reviewed the activities of the association during the past year and spoke of the many lines in which substantial headway had been achieved by its various committees. He then took up a discussion of present conditions and problems. One of the needs of the association is increased membership among engineers and companies and he strongly advocated a membership campaign along these lines. The present membership of about 140 companies represents an investment of $20,000,000 in round figures. In conclusion, Mr. Oppenheimer spoke of the numerous benefits of membership in the association.

Following the presentation of the report of the Executive Committee, and of Secretary-treasurer Gaskill and appointment of several committees, there was a round table discussion on the association's work.

The second session opened on Tuesday afternoon with the report of the Station Operating Committee, which was followed by a paper entitled "Daily Unit Data and Cost Systems," by J. M. Strike, of the Acme Power Co., Toledo. A spirited discussion followed in which R. G. Sloat, C. W. DeForest, H. W. Bromley, Wm. Long, H. B. Dates, W. L. Wallau and R. N. Clarkson participated. It was pointed out by several speakers that station records are primarily for attaining economy; therefore, they must be accurate, complete and accessible. It is not so much the form of the records as what they typify that spells their value.

On Wednesday morning the third session opened with the presentation of the report of the New Business Co-operations Committee, submitted by W. H. Matthieu. This outlined the valuable work carried on by the committee at its various sessions in different parts of the state in the face of numerous difficulties. The report covered, among other things, electric welding, the new Ohio State industrial lighting code now in tentative form, refrigeration, industrial electric heating, etc.

Prof. F. C. Caldwell, Ohio State University, discussed the Ohio factory lighting code and urged its importance not only from the standpoint of safety, but of increased production. The requirements of the lighting code must be made known by the central stations acting as a publicity medium. Professor Caldwell explained the present status of the code as not being mandatory but suggestive. Based on the experience obtained in its application, it is expected to make such revision as may be necessary and then make the code compulsory in about two years. He referred to opposition to the code by certain parties, especially in the steel industry, who fear heavy expense in putting it into effect; this is due chiefly to misunderstanding the objects and requirements of the code. He spoke of the educational work undertaken by the Ohio Electric Light Association, the State University and the central stations in teaching the scope of the code and its purpose. Numerous public hearings were held before the code was formulated. Such hearings before formulation of laws have resulted in giving us better and fewer laws than if the laws are first passed and enforcement immediately attempted. In conclusion, he asked for criticisms of the code and for support and publicity of it by the association as a whole as well as by its individual members.

L. G. White, electrical engineer of the Ohio Public Service Commission, in a few words urged more carefully prepared rate schedules for central stations. A uniform rate schedule is needed; this should be drawn up on a rational basis. He cited examples of inconsistent and improper rates and said that the association is the right organization to take up the matter of standardized rate schedules and discussion of the fundamentals of rate-making. I. L. Oppenheimer also pointed out the vital importance of rates to all utilities, since both company and customer are alike affected.

William McClellan, vice-president of the Cleveland Electric Illuminating Co., made an address on the problems of the days. Local problems have largely been overshadowed by the universal problems of the war, yet an important local problem is the working out of the social upheaval created as the result of the new conditions during and following the war. He said we must all keep our feet on the ground. No real progress is made by revolution but by evolution. It is not what one spends but what one saves that is important. He emphasized the value as a citizen of the property owner, whether of land, home or Liberty bonds. The property owner is a better citizen and not so susceptible to radical social doctrines. He advocated extensive ownership by the public of utility stocks as probably the best means to stop the movement for municipal ownrship. The thrift movement is likely to result in a large part of the public investing in utility securities.

At the fourth session on Wednesday afternoon Col. Ralph D. Cole, Columbus, O., made an intensely interesting address, reciting some of his war experiences. The report of the Meter Committee was presented and discussed. The fifth session was held on Wednesday evening and consisted of a lecture and demonstration by William A. Durgin, Commonwealth Edison Co., Chicago. This dealt chiefly with the productive value of modern industrial illumination. He pointed out its numerous advantages and how readily these may be attained. This lecture was very largely attended by ladies as well as men, about 100 lighting salesmen from Toledo, Cleveland and other nearby cities coming especially to hear it. Mr. Durgin's lecture was followed by the exhibitors' carnival and by a display of moving pictures.

A feature of the convention was the extensive displays made by exhibitors, the exhibition being larger than any ever held at a state convention, it was declared. A report of the sessions on Thursday and Friday will be given in our next issue.

TRACITON LINES NEED A BILLION DOLLARS YEARLY TO MEET DEMANDS.

Interesting Facts Brought Out by Experts in Hearings Before Federal Electric Railways Commission at Washington, D. C.

The problems of the street railways of the United States, which assume a graver aspect from day to day, are being given careful consideration in hearings before the Federal Electrical Railways Commission, created by President Wilson to make a nation-wide study and report means for restoring street railway credit. Experts in this branch of public utility service are at Washington, D. C., appearing before the commission to present the case of the street railways. The testimony of these men bear out some interesting facts on the situation. It was the opinion of W. G. Bradlee, president of the Stone & Webster Management Corporation of Boston, that the traction lines of the country require about $1,000,000,000 each year to meet adequately the demands of the public. He declared that $600,000,000 to $7,000,000,000 new capital was added annually for extensions and improvements, and probably $350,000,000 for refunding of outstanding obligations, and that little has been done in the way of improvements in the last four years owing to unusual conditions. "There are only two ways to obtain this money," Mr. Bradlee said, "either through municipal ownership or through the establishment of some plan so that the private investor will feel that he can count on a reasonable return if he invests in street railway securities."

Guy E. Tripp, chairman of the board of directors, Westinghouse Electric & Manufacturing Co., and chairman of the committee of 100 representing the American Electric Railway Association, in his testimony predicted that many of the larger electric lines would be in bankruptcy before the commission completes its hearings. Mr. Tripp told the commission he believed the fairest method for calculating earnings would be to take the issues of securities, determine whether the money they produced was put in the properties, extract any "water," and use the result. Questioned by members of the commission, Mr. Tripp said great fortunes had been made by street railway corporations in the past, but not through revenues from fares. A return was never paid on a 5-cent fare, he said, but "hopes were capitalized and hopes were sold." He blamed stock watering, high costs of labor and materials, and the present methods of dealing between traction companies and cities for the difficulties of many companies. He said the nickel fare should be made 10 cents and predicted that while the inquiry goes on many companies will go into bankruptcy.

Bentley W. Warren, counsel for the corporation represented by Mr. Bradlee, read a letter from Edward N. Hurley, who was chairman of the United tates Shipping Board, who declared the war showed that adequate and efficient street railway facilities are as essential to cities as transcontinental lines are to the country at large. "They should," declared Mr. Hurley in his letter, "be fostered and safeguarded accordingly. It appears to me that there is only one remedy, and that is authority to increase the fares."

Mr. Bradlee said his company had experimented with gasoline busses and that none of them paid. Asked about Henry Ford's idea that he could solve the street railway problem with a gas car, Mr. Bradlee said Mr. Ford had "an idea and not a car."

DEVELOPMENT OF CENTRAL-STATION SERVICE FOR NEWSPAPERS.

Practically All the Big New York Dailies Are Customers of the New York Edison Company's Service.

The contemplated moving of the *New York Sun*, one of the country's best-known newspapers, to its new and larger quarters in the old Stewart Building, at Broadway and Chambers street, New York City, has brought to light some interesting electrical data. *The Sun* was one of the earliest converts to central-station service among the metropolitan journals, having closed down its own generating plant in 1898, in favor of electric supply from the New York Edison Co. By this act, *The Sun* became the largest customer on the Edison mains and detailed tests were made of its supply and service.

Thus, records show that the lamps used averaged 13.7 cp., with a consumption of 4.11 watts per cp. With the improved types of lamps now available, *The Sun* will have a consumption of only about 1 watt per cp., thus obtaining a 400% increase of lighting efficiency during the 21 years of central-station service. In 1898, when *The Sun* abandoned its own lighting plant, the Edison wholesale rate then in effect had a maximum price of 10 cents per kw-hr., with discounts depending on consumption and use, giving possible minimum of 5 cents per kw-hr. for light and 4 cents per hp-hr. for power. With the increased lighting efficiency now available, and the lowered Edison rates since 1898, *The Sun* now gets eight times as much light for every dollar expended as it did 21 years ago.

That *The Sun* became a genuine advocate of central-station service for newspaper use has been twice proved, for when the paper moved in 1915 to the American Tract Society Building, the plant then existing there was also abandoned, and Edison service contracted for. Anticipating the coming move to still larger quarters, Edison service has been adopted for the third time. Additional equipment has been ordered, including new electric melting pots for the linotype machines, while the hydraulic elevators in the Stewart Building will be electrified.

From the standpoint of the central station, it is interesting to note that all but two of New York's big newspapers are customers of the New York Edison Co., the list of journalistic users including the *New York Times, World* (morning and evening), *Sun* (morning and evening), *Globe, Mail, Evening Post, American* and *Journal*. The *Herald* and *Tribune* buildings still maintain isolated plants, but electric supply for the newspapers concerned is protected by large "breakdown" contracts with the New York Edison Co.

FEDERAL TRADE COMMISSION URGES FIXING OF RESALE PRICES.

Recommends Congress to Pass Enabling Act on Resale Prices, Subject to Review by Disinterested Body.

The Federal Trade Commission in a special report to Congress has renewed its recommendation made last December that manufacturers be permitted by law to fix and maintain resale prices, subject to review by a disinterested agency.

The Commission says that such a law would remove present complexity in the business world, promote the efficiency of manufacturing and commercial institutions and serve the interest of the consuming public.

Under this recommendation, manufacturers desiring to fix and maintain resale prices would file with an agency to be designated by Congress, descriptions of their articles, contracts of sale, and the price schedules to be maintained. The disinterested agency would be charged with the duty, "upon complaint of any dealer or consumer or other party at interest," to review the terms of contracts and prices.

The Commission's recommendations, it stated, were based on the following conclusions:

(1) That producers of identified goods should be protected in their intangible property right or good will, created through years of fair dealing and of sustained quality of merchandise.

(2) That the unlimited power both to fix and to enforce and maintain resale prices may not be made lawful with safety; and

(3) That unrestrained price-cutting is not in the public interest, and tends, in the long run, to impair, if not destroy, the production and distribution of articles desirable to the public.

"There must be a common ground," the Commission said, "wherein the rights of producer, purveyor and consumer may each be fully secured and equity done to all. The search for such a ground has been a task of the Commission."

NEW YORK SURFACE LINES TO CHARGE FOR TRANSFERS.

Two-Cent Charge Permitted at 99 Transfer Points for Period of a Year.

Public Service Commissioner Lewis Nixon, of New York City, has issued an order permitting Job E. Hedges, receiver of the New York Railways Co., which operates certain surface lines, to charge two cents for transfers at 99 of the 113 transfer points throughout the city. The order, which is in the nature of a compromise between that demanded by the receiver and the wishes of the municipality, is intended to provide only temporary relief to the surface lines since it will expire on July 7, 1920, one year from the date of issuance. Limitation of the effectiveness of the order to only 99 transfer points was made necessary by the fact that the franchises under the provisions of which the street railways operate specify free transfers at 14 street intersections. The receiver requested permission to charge three cents for transfers, but the municipal officials contended that the necessity for any charge has not been shown.

Commissioner Nixon stated that if at the end of six months the city is not satisfied with the apprasial of the receiver, it is authorized to apply to have this proceeding reopened. The order was made upon condition that the lines of the company are not disintegrated.

AIMS AND ACTIVITIES OF ASSOCIATED GENERAL CONTRACTORS.

First Issue of Members' Monthly News Letter Being Distributed—Association Active in Legislative Work.

The first monthly edition of the Members' News Letter published by the Associated General Contractors of America is now being distributed. The publication contains a brief outline of the organization, its purposes and activities. The association is composed of general contractors, either individuals, firms or corporations, who have been for at least two years in general contracting and who have established a reputation for skill, honesty and responsibility. They must also undertake work in its entirety, partly at least with their own constructing forces.

The objects of the association are to promote better relations between private owners and public bodies, their architects or engineers on the one hand, and contractors on the other; to maintain high professional standards in the conduct of work; to combat unfair practices; to encourage efficiency among contractors; to support contractors and contractors' associations in efforts to rectify conditions of an unsatisfactory character; to encourage those methods of contracting for work which relieve the contractor of improper risks, and to encourage sound business methods tending to raise the standing of contractors generally in the business world.

The association has been actively engaged in legislative work on bills that affect construction activities and has succeeded in having several very satisfactory measures brought up principally with regard to war work. Several committees have been appointed to investigate and report on subjects of interest to contractors and field secretaries have been established in Chicago, New York, Atlanta, Washington, St. Paul, etc., as the first step in establishing closer contacts with its widening membership. It has also undertaken to develop a stand and rental charge on equipment used in construction work and to establish contract forms. In regard to the latter topic, it proposes to make a careful study of existing forms of every kind and in co-operation with the engineers and architects to eliminate unfair practices and to establish clear, definite, and equitable clauses in contracts.

D. A. Garber, North-Eastern Construction Co. of New York City, is president of the association and its headquarters are at 111 West Washington street, Chicago.

ELECTRIC CLUB OF CHICAGO TO HAVE BIG OUTING.

Eleventh Annual Basket Outing at Ravinia Park—Athletic Events, Music and Other Attractions.

Following its annual custom, the Electric Club of Chicago will have an all-day outing at Ravinia Park, about 20 miles north of Chicago, on August 21. As usual, a very large number of prizes have been donated by electrical firms of Chicago and these will be awarded for a great variety of races and other athletic contests for the children as well as adults and also for certain guessing contests for those not in condition to engage in strenuous athletic effort.

The committee in charge of the outing announces that for those electrical men who are unable to attend the outing personally special arrangements will be made to take care of their families so that they may be represented. The tickets to the outing will also permit members and their families and friends to stay for the grand opera performance in the evening, if they so desire, this being a regular feature of the evening programs that has made Ravinia Park noted in the Chicago district.

REFUSE COLLECTION BY ELECTRIC TRUCKS FOUND ECONOMICAL.

Experience of City of Sheffield, England, Very Satisfactory—Plans to Use More Electrics.

J. A. Priestley, cleansing superintendent of Sheffield, England, has prepared an improved scheme for collecting and disposing of house refuse, which will require four additional motor vehicles or 12 horses and wagons. According to the *London Electrician,* he states that the experience of the past four years with electric vehicles has been eminently satisfactory, and has demonstrated that the work can be done by their agency more expeditiously and economically than by horse labor. For house-to-house collection work the electric vehicle cannot be approached by gasoline motors. Steam wagons approach more nearly to the electrics in suitability and economy, but the latter possesses advantages in noiselessness and ease of maneuvering that are not shared by steam wagons, and require also the services of one man only to drive them, and that not necessarily a skilled man. The total weight of refuse collected in the city during the past year was 110,855 tons, an average of 2131 tons per week; but, as the amount varies as between summer and winter, the maximum amount to be collected during the heaviest period of the year is about 2600 tons weekly.

To collect this quantity of refuse by electric vehicles will require about 60 electrics, or, allowing a 10% margin to cover breakdowns, 66 vehicles would be necessary. The city has at present 12 vehicles in use and three on order, and the full program would therefore require the provision of 51 additional machines. For charging the batteries of this number of vehicles three 100-kw. motor-generators would be required, in addition to present charging facilities, and, as a stand-by machine is imperative, four generators of this capacity should be provided. Charging panels, switchboards, measuring instruments, etc., would also be required in proportion to the vehicles, and the total cost of the equipment would be about $500,000.

GENERAL ELECTRIC'S CONTROL OF TRUMBULL COMPANY CONFIRMED.

Trumbull Electric Manufacturing Co. to Retain Name and Management Though Controlled by General Electric Co.

The statement in our issue of last week respecting the acquirement of controlling interest in the Trumbull Electric Manufacturing Co. has been confirmed by the following official announcement:

"The General Electric Co. has acquired an interest in the Trumbull Electric Manufacturing Co., of Plainville, Conn. The present management of the Trumbull Electric Manufacturing Co. still retains a financial interest in the company and will continue in active charge of its manufacturing and selling policy.

"The Trumbull Electric Manufacturing Co. has an enviable reputation, national in its scope, as large manufacturer of knife switches and safety-first iron-box enclosed switches, as well as a general line of miscellaneous supplies, and the General Electric Co.. believing in the great future of the safety-first movement, feels that an alliance between these two leading manufacturers of goods designed to promote the safety-first feature in service-entrance switches, motor-control devices, etc., will give considerable satisfaction not only to the present customers of the Trumbull company, whose name will remain unchanged, but to the trade in general."

AERIAL MAIL DELIVERY OF LAMPS STARTED BY EDISON LAMP WORKS.

New Mazda C-4 Lamp Shipped Safely About 500 Miles Within Twelve Hours.

Tuesday, July 8, marked the new day in the transportation of lamps from manufacturers to distributors. On that day, the Edison Lamp Works of General Electric Co., Harrison, N. J., delivered to the Republic Electric Co., Cleveland, Ohio, one of the new Mazda C-4 tipless lamps, via aerial mail service.

The regular mail plane left Belmont Park, New York, at 5 a. m., arriving in Cleveland about noon, and the lamp was delivered to Louis Griesser, president of the Republic Electric Co., in good condition, through the regular post office channels.

The transportation department of the Edison Lamp Works announces that it is now ready, in cases of emergency, to make delivery of lamps by airplane in all sections of the country covered by the Government aerial mail service.

It is expected that Heller Field at Newark, the largest Government landing field for aerial mail service in the East, will be ready for use shortly, and this will make for even quicker service.

Packages shipped by aerial mail are limited to 30 in. in length and girth.

NEW SUBWAY LINK OPENED IN NEW YORK CITY.

Train service on the new extension of the Brooklyn Rapid Transit subway between Times Square and Fifty-seventh street in New York City was initiated at midnight on July 3. The extension of the service to Fifty-seventh street is the addition of another link in the line from Coney Island through Brooklyn to lower Manhattan, and along Broadway and Seventh avenues to Central Park, then east to Long Island through the Sixtieth street tunnel under the East River. Local train service will be maintained north of Times Square. Express service will be maintained between Times Square, Manhattan, and Pacific street, Brooklyn.

The service is expected to be extended to Sixtieth street and Lexington avenue before September 1, and through the Sixtieth street tunnel to Queensborough Plaza soon after January 1. Track laying in the tunnel section of the line, which was started about July 1, is expected to be completed in about four months.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS.

From a technical point of view, the Chicago meeting of this Institute, Sept. 22 to 26, inclusive, promises to be one of the most interesting in its history. The wealth of material in the line of technical papers for discussion is greater than has been offered for any previous meeting; upwards of 150 papers have been submitted to the committee, which finds it no small task to arrange a program to present this number with a minimum of conflicts among papers on allied subjects.

One of the excursions to be made by the Institute as a body during this meeting is to the LaSalle district. A special train leaving Chicago early Thursday morning will take the members and guests to LaSalle, Ill, where automobiles will convey the different parties to the coal mines, cement works and zinc smelters; for the ladies and others of the party not particularly interested in these industrial operations, the LaSalle hosts plan an automobile trip to Starved Rock and nearby points of scenic and historic interest.

BROOKLYN TRANSIT RECEIVERSHIP COVERS SURFACE LINES ALSO.

The Brooklyn Rapid Transit receivership was extended on July 14 by Federal Judge Julius M. Meyer so as to place Lindley M. Garrison, the receiver, also in charge of the surface railways in Brooklyn. Previously only the Brooklyn Rapid Transit Co. and the elevated and subway lines of that system were included in the receivership. The extension was made to cover the Brooklyn Heights Railroad Co., the Nassau Electric Railroad Co., the Brooklyn, Queens County & Suburban Railroad Co., and the Coney Island & Brooklyn Railroad Co., which, through leases, virtually control all Brooklyn Rapid Transit lines to Brooklyn.

PUBLIC SERVICE RAILWAY EMPLOYES GRANTED INCREASE.

The employes of the Public Service Corporation of New Jersey that operates the street-railway systems in Jersey City, New Brunswick, Edgewater, Paterson, and other nearby municipalities have accepted the award of the War Labor Board granting increases in wages. The men demanded 65 cents an hour and an eight-hour day, but were granted ten hours' pay for nine hours' work. The award amounts to about 55 cents an hour, an advance of 5 cents. The decision made the pay retroactive to May 1 and directs the corporation to pay about $30 to each of its 4500 employes.

LORAIN INAUGURATES BUILDING CAMPAIGN.

With 200 houses under construction, a campaign has started in Lorain, O., which has as its slogan: "A Thousand Homes This Summer." Houses are being rented before the ground is broken.

J. B. Johnson, general manager of the Lorain County Electric Co., a Doherty property, reports that building activity is also going on in Elyria at a rapid rate. Over eighty homes are under construction there and permits recently have been issued at the rate of ten a day.

COPPER SUBSTITUTES FORBIDDEN FOR ELECTRICAL WORK IN NORWAY.

The shortage of copper, from which all Norway, but especially the electrical works of that country, has suffered through war conditions, no longer exists. America is now in position to deliver the whole of the metal purchased long ago on Norwegian account. In consequence of this, the electrical works at Christiania have forbidden the continued use of zinc and iron as electrical material. From July 1, 1919, only copper is to be used for electrical purposes. The imports from America will include large quantities of line wire.

SMELTER PRODUCTION OF COPPER DURING THE YEAR 1918.

The smelter production of primary copper in the United States during 1918 was 1,908,500,000 pounds, which, if compared with the production in 1917, 1,886,000,000 pounds, shows an increase of 1.17%. The total value of the output in 1918, at an average price of 24.7 cents a pound, is $471,408,000, against $514,911,000 for 1917.

ELABORATE PLANS MADE FOR BRITISH PEACE ILLUMINATION.

The British Electrical Development Association held a meeting in London on July 1 to consider the following points: (1) Provision of lamps for peace illuminations; (2) provision of strip devices and other material; (3) rates to be charged by electricity supply undertakings; (4) provision of additional or heavier service connections where required.

Commercial Practice

Rapid Increase in Power Load—Electrics Meet Favor in Delivery Work—Employes' School of Dayton Central Station

PUBLIC SERVICE COMPANY INCREASES LOAD BY 9809 HP. IN FIVE MONTHS.

Large Increase in Load Contracted for by Public Service Co. of Northern Illinois.

New electric power business contracted by the Public Service Co. of Northern Illinois in the period between Jan. 1 and May 31 this year amounted in the aggregate to 9809 hp. In the same period of 1918 the total was 4398 hp. and in 1917, 5900 hp. Thus the total of each of the previous years' first five months' business was greatly exceeded. Considerably more than half the power load which it was calculated should be secured in 1919 was entered up in contract form in these five months. In detail the figures which represent 382 contracts are as follows:

Jan. 1 to May 31, 1919.

Division.	Hp.	1919 Allotment, Hp.
A	3301.3	3000
C	354.2	2000
D	1066.5	3000
E	109.2	500
F	3176.2	3000
J	1109.9	3000
K	231.0	1000
L	114.0	250
O	95.1	100
R	135.1	150
S	117.3	1000
Total	9809.8	17000

Numbers of the contracts made were for large amounts of energy, some of them providing for big installations with exceedingly heavy connected loads. It is interesting to note that of the total figures shown in the list, 95 hp. represents the demand made by electric ranges installed. Not appearing in the table of new business there were also renewals of contracts for the same purpose reaching 309 hp.

In the month of June the company kept up its stride and landed new customers whose power requirements reached upwards of 1500 hp. Among these is the Construction Materials Co. at Waukegan for about 600 hp. in which installation a 500-hp. motor will be put in service. The Armour Fertilizing Works at Chicago Heights were connected up for 700 hp. to be employed in uses requiring a number of different sized motors. Other contracts included one for 75 hp. with R. F. Conway & Co. at La Grange, and one with the Oak Park Baking Co. at River Forest for 82 hp. additional.

ELECTRIC TRUCKS IN DEPARTMENT STORE WORK.

Gimbel Brothers, New York, Augment Their Electric Vehicle Fleet.

Gimbel Brothers opened their New York department store in 1910. At that time they purchased a fleet of 88 electric trucks. In 1918, after eight years' use of electric transportation, they purchased 11 additional electric commercial vehicles, and in the early part of 1919 further augmented their fleet by 9 additional electric trucks.

The nationally known department store business of Gimbel Brothers has been served adequately by electric transportation for a period of approximately ten years—long enough for a comprehensive trial. The best proof that the electric truck has made good is the repeat orders by this concern whose success in business is largely dependent on efficient, economic, dependable transportation—the sort rendered by electric trucks.

The electric commercial vehicle is the standard mode of transportation as employed extensively by many of the great department stores in this country and abroad. For example, Marshall Field & Co., Chicago, Ill., uses 264 electric trucks, while Harrods, Ltd., London, England, employs 72. Space does not permit a complete list of department stores using large electric vehicle fleets, but the above may be taken as indicative. The "electric" has proven, by long experience, that it is the ideal truck for such frequent-stop transportation service.

PITTSBURGH NEWSPAPER ADOPTS BIG ELECTRIC SIGN.

Sixty-four Thousand Candlepower Sign Lights Up Newspaper Office.

A large electric sign has been installed upon the roof of the Highland Building, Pittsburgh, Pa., by the Duquesne Light Co. The sign advertises two of Pittsburgh's daily newspapers, namely, the *Morning Gazette Times* and the *Evening Chronicle Telegraph.*

The sign, which is illuminated on three sides, is rated at 64,000 cp., and contains 3200 25-watt lamps which consume 80,000 watts per hour, or 150,000,000 watts per annum. Each letter is 10 ft. in height. The Highland Building is the tallest structure in the East End section of Pittsburgh. The illumination from this sign improves the lighting of the streets for several blocks and can be seen for a radius of 10 miles. Energy for lighting is furnished by the Duquesne Light Co.

ENERGY CONSUMPTION INCREASES TWICE AS FAST AS POPULATION.

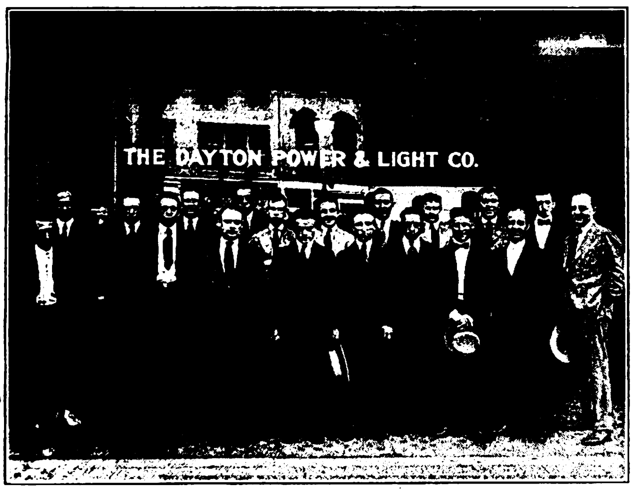
In his presidential address to the Pacific Coast Section of the National Electric Light Association at its recent convention in California, Samuel Kahn, vice-president of the Western States Gas & Electric Co., said:

"Not long ago a statistician compiled figures to indicate that the number of kilowatt-hours of electricity used increases more rapidly than the square of the population; in other words, if the population is doubled the energy consumption is more than quadrupled. Therefore, if the population of the Pacific Coast doubles within the next ten years, the use of electricity will be four or five times as much as at present. Figures recently published by the Bureau of the Census, Department of Commerce, indicate that the central stations of California during the year 1917 generated 2,746,000,000 kw-hr. of electrical energy as against 661,000,000 kw-hr. in 1907, an increase of 315%.

"These figures bear out the statement regarding the consumption of electrical energy and should be instilled in the minds of every thinking man and woman, for they must come to realize that the solution and responsibility of furnishing this energy rests with men trained to that particular industry, as they are in position to render that service, taking all factors into consideration, at less cost than a governmental agency."

ELECTRICAL SCHOOL OF DAYTON POWER & LIGHT COMPANY OPENED.

The co-operative school of the Dayton (O.) Power & Light Co. opened July 1 with 18 high-school graduates in the class. They will be given a thorough course in electricity and then later trained in the different branches of the company to which they seem most adapted. Some will enter the sales department, where a thorough course of salesmanship will be given them. The others will take a finished course in meter construction, testing, etc. This school is open to any high-school graduate and he is paid 30 cents an hour while attending the school and will later be placed in



Student Class of Dayton Power & Light Co.

some department of the company and his advancement is assured. This school was found to be absolutely necessary by O. B. Reemelin, general superintendent of the company, on account of the rapid growth of the company and because of the shortage during the past two years of young men owing to the war. Those finishing the course and passing an examination will be able to take a position in the department to which they show adaptability that would otherwise require a year or more time in the regular way of working. The Dayton Power & Light Co. is supplying service to some 46 communities such as Dayton, Piqua, Xenia, Wilmington, Jamestown and Germantown. It is operating three city car lines in Dayton and one suburban line, also 85% of available factory business in Dayton and other cities it serves.

During the war the Dayton Power & Light Co. supplied all the power used in the manufacture of war munition. It also is supplying power for all the Conservancy work, going so far as to operate the motors on the dredges at present engaged in straightening the Great Miami river.

UTILITY COMPANIES RESPONSIBLE FOR MOST OF OUR COMFORT.

Paul Tomlinson in *McClure's Magazine*, says:

"We have the public service corporations and the public utilities companies to thank for supplying us with most of the things which make our lives so comfortable. When we press the button which controls the electric lighting in our homes do we stop to think that at the heart and center of the maze of wires, over which runs the current responsible for our light, there is a great power house? That this same plant perhaps is sending out the power which carries us along so swiftly in subway trains or electric cars? That this power plant is the basis of a great industry, the result of modern science, industry and engineering skill? It may be that a great river has been harnessed and Nature made to work for us. Who knows the imagination, courage, and labor which have made it possible for us to live and travel about in comfort and convenience?"

SPARE-TIME SALES STIMULATE APPLIANCE BUSINESS.

The experiment tried out by the Public Service Co. of Northern Illinois some time ago, of giving commissions for appliance sales made by employes during spare time, has proved very successful. The offer applies only to employes outside of the sales department and the result has been not only increased sales of all kinds of appliances but greater interest on the part of all employes in the development of new business. Many leads are furnished the regular sales force by employes who heretofore paid little or no attention to company business outside of office hours.

As an indication of the direct results of the plan, four employes sold appliances valued at practically $6000 during the 6 months ended July 1, all sales being made during spare hours.

WHAT THE ELECTRIC STEEL FURNACE MEANS TO CENTRAL STATIONS.

The war brought forcibly to the fore the value of the electric furnace for steel making and refining because the demands of war create severe requirements that steel must meet. And steel made electrically meets the conditions imposed.

There are at the present time some 330 electric furnaces for steel production in this country. These furnaces consume about 750,000,000 kw-hr. when operating at capacity and are able to produce about 1,400,000 tons of castings and ingots.

A FAN FOR EVERY SLEEPING ROOM.

Henry L. Doherty has said that he would consider himself a great humanitarian if by his efforts there was an electric fan used in every sleeping room in the country, his idea not entirely being from the standpoint of promoting electricity, but for the promotion of that very inexpensive commodity known as "fresh air."

Operating Practice

Moisture Content of Coal — Cleaning Condensers — Boiler Tests with Powdered Coal — Problem of Neutral Current

VARIATION OF MOISTURE CONTENT OF COAL IN TRANSIT.

Tests Show Variation With Grades of Coal and With Seasons.

In transit between coal mine and power plant or point of consumption, coal is subjected to the influence of the elements. All coal, until treated, contains moisture. Coal in transit contains moisture, and whether the moisture content increases or decreases in transit depends upon several factors, the chief of which are the weather, the time the coal is in transit, the form in which the coal is shipped, and the distance of travel.

Some companies pay for their coal and the freight charges as weighed at the mine, others pay for the coal as weighed by the railroads at the point of delivery. In other instances, of which there are only a few, the coal and the freight charges are paid according to the weight as determined by the central station at its power houses. While this latter is most uncommon, it is the method in vogue with the Commonwealth Edison Co., one of the largest consumers of coal in the central-station industry.

This company has carried on extensive tests to determine the variation in moisture of coal in transit from the mines to its generating stations. A large number of samples were taken at the mine and when delivered, and the moisture content in both instances determined. The accompanying diagram shows the variation of moisture content of several different coals during the different seasons of the year.

The tests extended over a period of some 14 months and have shown that the average moisture content of coal as unloaded at the generating stations during the year varies but little from the moisture content as loaded at the mine. The moisture content does, however, vary with the seasons. For example, samples taken from Sept. 1 to Dec. 31 showed an average increase of moisture content of 0.34%; from Jan. 1 to March 31, an increase of 0.70%; from April 1 to June 30, a 0.12% increase, and from July 1 to Sept. 30 an increase of 0.28%.

A further instance of the changes with the seasons is afforded by comparison of the moisture content of coal unloaded during September and October of two consecutive years, shown in the following:

	Total precipitation.	Moisture in coal.
September of two consecutive years..	3.53	13.7
	2.24	13.0
October of two consecutive years....	0.40	13.4
	3.85	14.1

Coals from different localities behave differently as regards absorption of moisture. It was also found that the amount of moisture retained by saturated screenings depends both upon the relative quantity of fine particles and the nature of the coal.

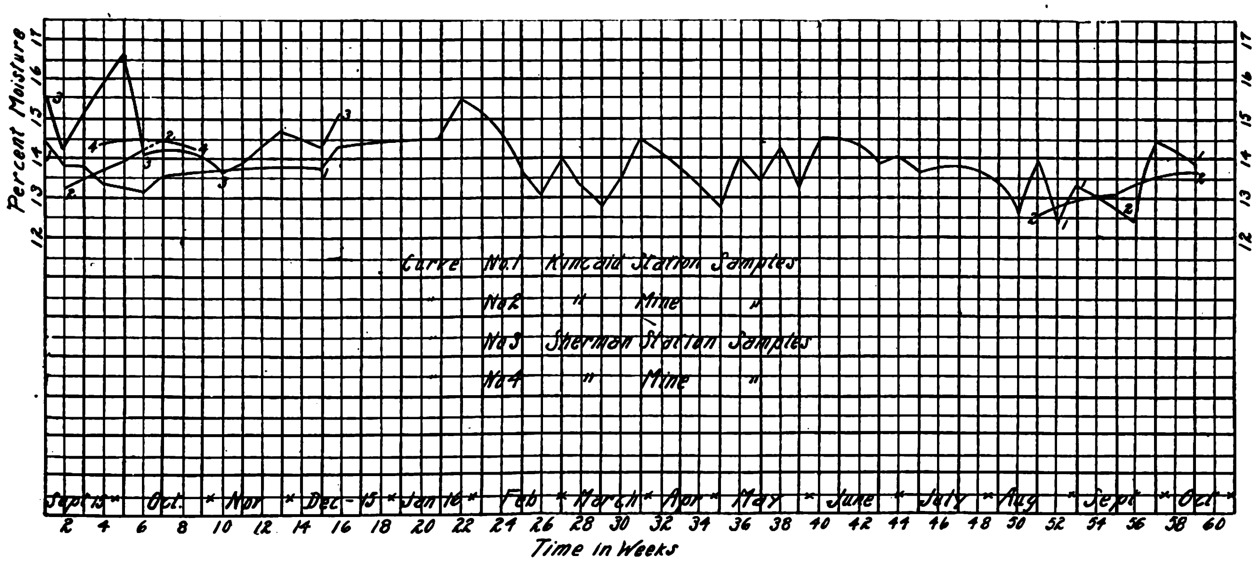
Greater differences were found between coals from northern and southern fields than between samples of the same coal having wide variation in average size.

SAND IN CIRCULATING WATER CLEANS CONDENSER.

Periodic Treatment With Sand Delays Growth of Deposit in Tubes.

The problem of cleaning surface condensers is often a difficult one, because of the large number of tubes requiring cleaning and because of the short time available between the time a machine can be taken out of service and when it must be ready again.

The use of compressed air and sand, compressed



Curve Showing Variation of Moisture Content in Coal With the Seasons.

air and a wad and the wire brush are some of the methods employed for cleaning the inside of tubes. The use of kerosene is also adopted sometimes. All these methods, except that of employing kerosene, necessitate taking the machine out of service and necessitate a somewhat protracted delay.

A method that has been employed with considerable success in some cases is to maintain a gradual cleaning process during operation. This can be done in the following manner. Sand is introduced into the condenser with the cooling or circulating water. About 1.5 cu. yd. of sand per day or thereabouts seems to suffice when this treatment is kept up for about three weeks. The tubes can be kept fairly clean in this way without the condenser being taken out of service. Such treatment might enable higher vacua to be maintained during the summer months and at other times where capacity does not permit of units being taken out of service for cleaning.

Experience will show the minimum amount of sand required for a given velocity of water through the condenser. More than this should not be used because of the scouring action of sand and its effect of reducing the life of the tubes.

BOILER TESTS WITH PULVERIZED COAL AS FUEL.

Operating Results Obtained on 468-Hp. Boiler Show High Efficiency.

The following report of a test of a 468-hp. water-tube boiler was presented by N. C. Harrison in his paper entitled "Pulverized Coal as a Fuel" read before the June meeting of the A. S. M. E. in Detroit. The installation is noteworthy not only by reason of the high efficiency obtained, but also because of the fact that it has made clear some of the conditions necessary for the successful operation of boilers utilizing powdered fuel.

When the boiler was first put into operation, a number of undesirable conditions resulted. An insufficient air supply caused high-furnace temperatures resulting in fusion of the ash particles and a consequent accumulation of slag between the tubes, on the furnace walls and in the ashpit. The removal of the molten slag presented considerable difficulty. It was also found that the combustion chamber was of insufficient size. High gas velocities resulting from insufficient air in the chamber tended toward destruction of the refractory surfaces of the furnace.

A new furnace was, therefore, designed. The combustion chamber was enlarged and a regulated air supply was provided for by means of a number of auxiliary air openings equipped with dampers. The accumulation of slag in the pit was prevented by raising the point of admission of the fuel into the furnace. As a result the flame path has been raised above the base of the pit, hence particles of ash dropping from the flame are not fused. The ash, therefore, can be drawn from the pit in the form of a powder and small slugs of slag. Analysis has shown that the ash contains practically no carbon.

Having established satisfactory furnace-operating conditions, a series of efficiency and capacity tests were conducted preliminary to proving the contract guarantees. The brickwork was then given a thorough trial by carrying the boiler at a continuous rating of 180% over a period of several days. On August 12 and 13 a final efficiency test, the results of which are given below, was run. The boiler is a three-pass water-tube 468-hp. boiler, equipped with a superheater.

LOG OF TEST OF A PULVERIZED-FUEL-BURNING STATIONARY BOILER.

Make of boiler	Edge Moor
Rated hp.	468
Heating surface, sq. ft.	4,685

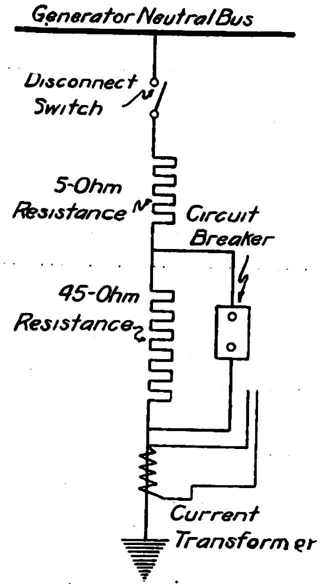
NEUTRAL RESISTANCE REDUCES INDUCTIVE INTERFERENCE.

Reducing Neutral Current by Resistance, Problem of Relay Performance.

By B. M. Smith.

The problem of dealing with inductive interference between heavy current lines and small-current lines, the one for transmitting power and light and the other for telegraph and telephonic messages has received much attention of recent years due to the ramifications of both forms of lines and the frequency with which these lines come into close proximity to one another. Both the A. I. E. E. and the N. E. L. A. as well as a number of public service commissions have taken up the subject of inductive interference. The subject is, therefore, a live one among operating engineers, both central station and telephone and telegraph.

In a recent instance that came to the attention of the writer complaints had been made that a high-voltage power transmission line was causing considerable noise in a telephone line during certain periods. The transmission line paralleled the telephone line, which was an important trunk line, for about 2 miles. This transmission line ties two generating stations together, these two generating stations being on different systems although operating in parallel. The noise in the telephone line was greatest when both stations were running together and the neutral at each station was closed to ground (the generators were star-connected machines, the units being turbogenerators). The noise was much less with the neutral of only one of the stations closed, and a minimum when both neutrals were open.



Layout of Resistors, Circuit Breaker and Disconnect Switch to Reduce Current in Neutral.

Finding the Cause of Inductive Interference.

The high-voltage transmission line consisted in part of aerial conductors and in part of underground cable. The aerial conductors were located in an equilateral triangle, an arrangement that tends to reduce induction and unbalanced static conditions between phases to a minimum.

The inductive interference commenced as soon as the transmission line between the two generating stations was placed in service, which was in the early spring. As it was at first thought the insulators might be the cause (before the effect of varying the neutral circuit at the generator stations was experimented with), these were tested and examined. Spring rains clean insulators and the sun dries them; cracks and broken petticoats on the other hand are weak places that cause leakage, which causes static interference with telephone wires in proximity. All insulators found defective were replaced with no effect upon the noise in the telephone lines.

Experiments with the neutrals of the generators showed that with both neutrals open the noise was a minimum, a maximum when both stations had their neutrals closed and somewhere between these limits when only one of the stations had its neutral closed to earth. It was also found that there was less noise with certain generators operating at each station with their neutrals closed to ground than when other generators were operated in the same way. The larger and more modern units created the least disturbance to the telephone lines. The distribution of load between stations and variation of total load seemed to make little if any difference in the noise induced in the telephone line.

The phenomena immediately suggested that the inductive interference was caused by the interchange of circulating current between the two generating stations, due to differences in wave-form, phase displacement, and, mostly, to the triple-harmonic current that would be short-circuited through the generators when the neutral at each station was closed. The wave-form at both stations was good and it was the consensus of opinion that it was the triple-harmonic that was the cause of the trouble.

Overcoming the Triple Harmonic.

By installing resistance in the neutral circuit it was found that the third-harmonic current could be reduced to such a value as to make the disturbance in the telephone lines almost disappear. Unfortunately the resistance that it was necessary to insert in the neutral circuit was of such a value that overload relays would not function when short circuits occurred in the underground cables between phases and sheath.

A recording ammeter was installed in the neutral to show the variation in circulating current through the earth. Measurements of effective resistance were taken to determine the resistance of the circuit between generating stations that the circulating current followed. It was found that the minimum resistance permissible if the relays were to be depended upon was about 5 ohms. On the other hand to reduce the noise in the telephone circuit to such a value that the telephone company were satisfied it was necessary to insert about 50 ohms in the neutral.

As telephone interference could not be tolerated nor could the idea of foregoing the protection of the overload relays it was decided to adopt a selective action by which the neutral current would be kept to the minimum where the telephone company were not interfered with during normal operation and yet where the neutral current would be able to increase during short circuits to sufficient value to enable the overload relays to function. In other words a resistance of 50 ohms was inserted in circuit during normal operation and so connected that it would be automatically taken out of circuit and leave only resistance of 5 ohms in circuit, when the relays functioned.

The above arrangement is obtained by employing two banks of resistance, namely 5 and 45 ohms respectively. The 45-ohm bank is shunted by a circuit breaker controlled by a current transformer located in the neutral circuit so that all neutral current passes through it. When a short circuit occurs between some phase and ground the current transformer operates to close the circuit breaker, which thereby cuts the high-resistance resistance bank out of circuit so far as affects the resistance of the neutral circuit, hence flow of neutral current. The relays then function because instead of 50 there is only 5 ohms in circuit.

In the diagram a disconnect switch is shown, the purpose of which is to enable the banks of resistance and current transformer to be isolated from the generator neutral bus should it be necessary to work on them. A spark gap may be inserted across the 50-ohm bank, but it plays no part in the reduction of inductive interference with the telephone line, but is used as a precaution to protect the underground high-voltage cable between generating stations, and of generators and station apparatus in case potential rises.

Contracting-Construction

Chicago License Fees to Be Raised—Lighting to Make Bank Building Conspicuous—Electrical Supplies for General Use

PROPOSED CHANGES IN CHICAGO CONTRACTORS' LICENSE LAW.

Ordinance Providing for Increased License Fees Expected to Bring Desirable Results—Inspectors' Salaries Raised.

An ordinance providing for several changes in the existing law governing the licensing of electrical contractors in Chicago was recently approved by a subcommittee of the City Council Judiciary Committee. The new ordinance which was drawn up by the local municipal inspection authorities in co-operation with the fixture manufacturers, contractors, and the local labor organization, is expected to do a great deal toward improving electrical contracting conditions in Chicago.

The principal change in the proposed ordinance is in the licensing fee, which has been considerably increased and divided so that different fees are charged for the various classes of work done. The present law provides for a charge of $25 for the original license with an annual renewal charge of $10. This license covers all classes of work. Considerable difficulty has been encountered due to the fact that this charge was so low that many electricians who were not strictly contractors could well afford to carry such a license, although actually employed as journeymen and do contracting work on the side. This not only made unfair competition for the legitimate contractor but caused trouble with customers, for no means were provided other than a revocation of the license which would force such men to install approved wiring. As a result many people were forced to have their wiring changed or repaired by another contractor after the work was supposedly completed. Furthermore, it is obviously unfair to charge the same license fee for all classes of work.

The new ordinance provided for the following license fees: General license, which enables the holder to do all classes of electrical work, $200, with an annual renewal charge of $50; electrical construction license, which allows the holder to do all kinds of construction work but does not include permission to manufacture or install fixtures, $100, renewal $25; fixture hangers' license, which permits the manufacture and installation of fixtures only, $100, renewal $25; sign license, which allows the erection and wiring of electric signs only, $25, renewal, $10; maintenance license, which allows the holder to make minor changes, repairs or alterations in existing wiring, $25, renewal, $10. The ordinance also provides for a surety bond which the applicant must secure and which insures the customer a proper installation but does not make the city responsible for the work. In addition, an examining board composed of representatives of the various branches of the industry will be established to determine the applicant's ability and responsibility. No license can be procured without the approval of this body.

The new ordinance further provides for changes in the payment of inspection fees. At present the fees are paid only by the electrical contractor, who is charged on a graduated scale per socket, for lights, or per horsepower. The fixture dealer is obliged to take out a permit for the fixture work but does not have to pay any fee.

Under the new ordinance the electrical contractor's fees will be based upon the circuit capacity to which will be added an additional fee for any drop cords, baseboard or wall receptacles that his men may install. The fixture dealer is also required to pay an inspection fee which will be based upon the number of sockets installed. The advantage of this new system is that the electrical contractor is enabled to determine more accurately the amount of his inspection fee when it is determined by the work which he installs. Under the old procedure this could not be ascertained until the fixtures were installed. As the inspector's approval could not be secured until this fee was paid it often delayed the use of the service.

At present the proposed ordinance is awaiting the approval of the Judiciary Committee and it is hoped that action will be taken immediately before the City Council adjourns for its summer vacation. Although some change will probably be made before it finally becomes a law it is expected that the ordinance will be approved and that as a result the electrical contracting conditions in Chicago will be considerably improved.

The Finance Committee of the City Council recently approved an increase in the salaries of the electrical inspectors. The bill provides for a yearly wage of $2400 dating back to Jan. 1, 1919, with a further increase to $2580 per year starting in August, 1919. The number of district inspectors was also increased to 44.

EXTERIOR LIGHTING OF BANK BUILDING PROVES SUCCESSFUL.

Contractors Often Neglect Opportunities in This Field—Features of Recent Installation.

Nearly every electrical contractor appreciates the value of outline or flood lighting on a building as an advertising feature, yet very few of them make any attempt to encourage the installation of such lighting unless the customer first requests their assistance. Perhaps the best field for such work is in the lighting of buildings occupied by firms that do a large amount of advertising but from the nature of their business do not have any use for display windows. Such firms for example, as banks and real estate offices, have nothing to display other than placards and very often have dark and forbidding exteriors. Such firms, however, are large advertisers and the electrical contractor will not have much difficulty in persuading them to install some form of exterior lighting, if he tries.

Although flood lighting is generally to be preferred for such work there are many cases where it is necessary or desirable to install a system of outline lighting on the building. Such a system was recently installed on the Peoples' State Bank building at 47th street and Ashland avenue, Chicago, by J. L. Burgard, an electrical contractor of that city, and has proven very satisfactory to the bank officials.

The building occupies one of the five corners formed by the intersection of three streets at this point. However, it was somewhat obscured because this particular corner set slightly back of the others, which were occupied by brilliantly lighted stores with attractive display windows. It was not considered advisable to install a flood-lighting system as it would be rather difficult to control it and some of the other building owners would not permit the flood lights to be installed on the roofs of their buildings.

The outline lighting as installed consists of 800 Cutler-Hammer Norbitt receptacles containing 25-watt Mazda B lamps arranged in a row along the top of the building. These receptacles are mounted on a channel-iron framework which extends about 12 in. out from the edge of the roof. In addition, 12 3-light showers equipped with 100-watt C lamps were installed at intervals about 2 ft. above. Over the main entrance to the building, which is triangular in shape, the system drops down to the level of the ceiling of the first floor and terminates at a flashing sign. All the sockets used were of the approved weatherproof type. The shower fixtures were also made by the Burgard company and are constructed entirely of conduit, the different pieces being held in place by outlet box covers through which they are run. Three No. 2 wires are installed in 1½-in. conduit from the main service located in the basement of the building to the roof where two cabinets are installed containing the necessary circuit blocks.

In order to demonstrate to the bank officials the effect of this system Mr. Burgard devised a clever method of illustrating it. An outline of the building was sketched on a piece of extra heavy paper. The lighting system was then drawn in and at the points where the lights were to be placed, holes were made approximately the size of the lights. On the back a piece of light yellow tissue paper was pasted. In this way by placing the drawing in front of a light stronger than the surrounding light, the proposed lighting effect on the building was clearly shown.

FIXING THE SELLING PRICE FOR SMALL MATERIAL PURCHASES.

Inability of Contractor to Give Definite Figure Causes Customers to Distrust Him.

There are a great many pieces of electrical construction material which can be used advantageously for other classes of works such as is usually done by the houseowner himself around the home. For example, conduit is often used for lawn fences where its rust-resisting qualities are very desirable. Locknuts, washers, screws, nuts, wire, etc., are other articles often desired and purchased from the neighborhood electrical contractor. While it is true that such sales are not sufficient to enable the contractor to realize any substantial profit from them, he can in this way render a service to the community which will improve his standing in it and at the same time often be the means of securing real business for him.

One of the most objectionable features in connection with such transactions, however, is the inability or timidity of the contractor to set a positive selling price for such material. Invariably he will state his price as "about so much," or "such a price to you," whether he is personally acquainted with the customer or not. This gives the customer the impression that the contractor does not know his business and leaves a doubt in his mind as to whether or not he has paid a fair price for the article. Nor does it gain the contractor the customer's friendship any more than if he had stated definitely the price of the article and suggested a further purchase.

As already stated the volume of this business is not great enough to warrant hiring a special salesman for such work or even to fix a price for every article in stock but it is much better to take a pencil and paper and figure out the price for every sale than to make a rough mental calculation and submit a vague figure. The contractor may also refer to the catalog or if he is a member of the National Association of Electrical Contractors and Dealers he may use his Universal Sales and Data book, which gives a resale price for material. The customer in the majority of cases realizes that such sales are out of the usual routine of the contractor's business and does not expect him to have the price already marked for the article, but he does expect that the contractor can get the price definitely and not guess at it.

Nor should he be afraid to give the price definitely including a sufficient margin to cover his overhead and profit. The cigar store dealer may be known to everyone by his first name, yet he sells everyone at a fixed price without endangering his business. Why then should the electrical contractor hesitate to state a definite price for such convenience purchases?

WIRING DATA FOR DIRECT AND ALTERNATING-CURRENT MOTORS.

The fourth edition of "Wiring Data for Direct and Alternating-Current Motors" has just been issued by the Oregon Insurance Rating Bureau, of Portland. Ore. This is a revised edition and has been compiled by F. D. Weber, chief electrical engineer of the Bureau. This 32-page booklet is a valuable collection of tables, formulas and other interesting information relative to the wiring of the more common types and sizes of motors. The following gives an idea of the principal contents of the book: Rules for load-factor or demand-factor allowance; feeder sizes for two or more motors; wiring tables for 115, 230 and 550-volt direct-current motors; specifications for motors operated on grounded railway circuits; intermittent-duty alternating-current motors; feeder sizes for alternating-current motors; wiring tables for single-phase, two-phase and three-phase of various voltages and types; stranded copper conductor data; copper busbar data; motor-wiring formulas for different types of current.

To persons or firms outside of the state of Oregon, this booklet will be sent for 30 cents on addressing the Oregon Insurance Rating Bureau, Box 745, Portland, Ore.

BOSTON ELECTRICAL CONTRACTORS FAVOR THE 44-HOUR WEEK.

At a meeting of the Electric Section of the Building Trades Employers' Association of Boston, held on July 1, it was decided as the sense of the meeting that a 44-hour week schedule be adopted. Representatives of 10 of the leading electrical contractors were present.

QUESTIONS AND ANSWERS

All readers are invited to submit questions and answers to this department. Anonymous communications will not be considered. Questions should relate to electrical matters of any kind. Answers contributed by readers should be submitted preferably within eight days of the date of publication of the question and should be limited, if possible, to 300 words. Payment will be made for all answers published.

Questions.

No. 464.—Transformer Design.—I am trying to build a transformer with 110-volt primary and 14 steps on the secondary varying by 7½ volts up to 105 volts, thus, 7½, 15, 22½, 30, etc. Each step must be capable of carrying 10 amperes. What size and amount of wire is necessary on the primary and secondary windings?—W. A. S., Augusta, Kans.

No. 467.—Operating Cost of Electric Household Refrigerators.—I would like to know from some reliable source what is the operating cost of the electrically operated refrigerators that are being recommended for household use. What is the experience as to their dependability?—R. H. T., New York, N. Y.

No. 468.—Wiring Lights From a Bell-Ringing Transformer.—Is there any provision in the National Electrical Code against reducing 110 volts to a lower voltage by means of a bell-ringing toy transformer and then wiring some small lights from this? Is it all right to run this wiring in the same way as ordinary bell wiring? If this is permitted, what is the highest voltage and wattage permissible on such bell wiring?—S. T. E., Bridgeport, Conn.

No. 469.—Length of Motor Branch Line.—What limit, if any, is there to the length of a tap line from a No. 0000 feeder to an autostarter for a 2300-volt motor? The tap line is to be No. 6 or No. 8 lead-covered cable run in conduit?—A. S. N., Plymouth, Mass.

No. 470.—Pulling in Lead-Covered Cable.—I would like information in regard to pulling lead-covered cable into iron conduit. What kinds and sizes of grips are suitable for use in pulling No. 0000 triple-conductor, lead cable of 2-in. outer diameter into 2½-in. conduit? Through how long a run and around how many elbows is it safe to pull this? I should like similar information regarding other cable sizes down to ¾-in. in diameter.—A. S. N., Plymouth, Mass.

Answers.

No. 462.—Electric Welding of Rails.—Is there a definite dividing line between spot and arc welding as to where one would be used and not the other, or does their utility overlap to a certain extent? I refer especially to the welding of street-car rails, for which both methods seem to have been used. Which method is preferred for this work?—T. N., Toledo, Ohio.

[One answer to this question was published in the issue of June 21, 1919.—Editor.]

Answer B.—There is no definite dividing line and the method used depends a great deal on the local conditions. Where the power is limited and only a few joints are to be made the arc welding outfit is generally used. The spot welder offers the advantage of heavy contact pressure, thereby making a lower resistance bond. The spot welder requires considerable power for shorter periods and consequently requires large machinery.

The spot welder is usually employed on large jobs and the arc welder on small jobs, the method used depending merely on the quantity of work and the distance and transportation facilities to the job with the equipment.

Wherever possible the spot-welded joint is used. Cost runs about $4500 for the first 1000 welds and about $800 for each additional 1000 welds. This cost is about twice that of the bolted type of joint. The Board of Supervising Engineers, Chicago Traction, made many tests on various bonding methods and these tests are found in its annual reports.—H. E. W., Chicago, Ill.

No. 465.—Underground Conduit.—The writer is about to install 4000 ft. of 1½-in. conduit underground to carry a No. 6 lead-covered single-conductor cable supplying a potential of about 1100 volts on a series "White Way" lighting system. As this conduit will only be about 8 to 12 in. under the sidewalk, I have been advised by an engineer of authority on metallurgy that a black iron pipe would last as long on this installation as galvanized conduit and he suggests that I use plain iron pipe and give it a good coating of asphaltum. The suggestion appeals to me from the standpoint of cost, which would only be about half as much as galvanized conduit and the material could be handled in 20-ft. lengths. I would like to take advantage of this suggestion, if practical, but don't want the cost to mislead me on a good job. I would like to hear from some of the readers experienced in this subject before going ahead with this installation.—W. W., Ludlow, Ky.

Before installing iron pipe for an underground duct line, standard 3½-in stone or tile duct should be given careful consideration. Stone or tile duct placed under a sidewalk would require little concrete work, and is probably the least expensive and most lasting duct line that can be installed. Careful consideration should be given to the future requirements of a given territory before installing a duct line. It generally pays to install at least a 4-duct line, unless there is no possible need for future circuits.—W. H. K., Evanston, Ill.

No. 466.—Grounding Transformers and Secondaries.—Up to the present time the undersigned has always grounded the neutral of secondaries on transformer poles, together with grounding the transformer cases at this point and installing the lightning arresters on the next pole away from the transformers. It is now strongly recommended by leading engineers that the lightning arresters be installed as near as possible to the transformers, which doubtless means on the same pole, and the neutral grounds will now have to be made at another point. I am in favor of this change and appreciate its protective advantages, but would like to hear from readers as to best location for the neutral grounds and their ideas on grounding the transformer cases. —H. M., Cincinnati, Ohio.

Answer A.—Electrical engineers are not of one opinion as to whether the grounding of transformer cases does result in additional protection against lightning. This subject is very much like that of a few years ago of grounding the secondaries where there were two different schools, one of which was strongly for and the other equally strongly against grounding.

Theory dictates that grounding transformer cases should reduce the likeliness of lightning damaging the transformer winding. Experience also proves that the theory is correct. The reason why transformer cases are not grounded to a wider extent than they are is because of the danger to linemen, the disadvantage in this respect offsetting the benefit of better protection against lightning.

It is not of extreme importance that the lightning potential between transformer winding and the earth or ground be kept down to a comparatively low value. On the other hand, it is extremely important that the difference of potential between primary and secondary, and likewise between primary, secondary and case be kept down to a safe value. Connecting the lightning arrester between primary winding and case, and further, connecting the transformer case to ground, accomplishes this.

It has been suggested to go a little further, namely, connect the transformer secondary and case to the lightning arrester through a small air gap. The effect of doing this is to enable a potential of several hundred thousand volts to exist between transformer and case, while at the same time the potential actually existing between transformer primary and secondary, and transformer windings and case, will be only a few thousand volts—perhaps eight or ten thousand—which a transformer subjected to the A. I. E. E. standard test could withstand.

Such an arrangement as explained above makes the protection of the transformer independent of the resistance of the ground resistance and eliminates the impedance of the ground wire between arrester and ground—a very great benefit where high-frequency discharges take place and the ground wire is long or of small cross-section. The actual benefit from grounding transformer cases will vary, and will, of course, be greatest in those localities where only high-resistance grounds can be obtained, and where long ground wires are employed.

The reason that the cases of distributing transformers are not grounded more generally than is the case, is chiefly for the reason that a grounded case creates a very real hazard for linemen working on the same pole with the grounded case. The hazard can be reduced by installing a link switch so as to disconnect the case from ground while men are working on the pole. This costs money, may be forgotten and adds a complication where conditions are already complicated enough.

As regards the location of lightning arresters, these should be installed upon the same pole as that on which are installed the transformers they are to protect. It has been shown conclusively by D. W. Roper in his papers before the A. I. E. E. and the N. E. L. A., that arresters are very much more effective in protecting when located beside the transformer than when even only one span away. The N. E. L. A. Handbook on Overhead Line Construction advocates installing the lightning arresters upon the same pole as the transformers they are to protect.

A transformer secondary should be grounded as near the transformer as possible. This means at the same pole. The lightning-arrester ground and the secondary ground wires should be kept separate and each should have its own "ground." Where a transformer case is grounded, the same conductor may be employed for the secondary. Secondary ground wires should be protected by wood covering up to about 7 ft. above ground at least.—B. M. S., Cicero, Ill.

Answer B.—For maximum protection lightning arresters should be installed on the transformer pole. The lightning-arrester ground and secondary ground should consist of two distinct grounds and should be on the transformer pole. In addition, the secondary should be grounded every 500 ft. The writer is not in favor of grounding transformer cases in the ordinary pole-type installation. A grounded case presents too large an area to be worked around safely. The linemen should be protected from arrester and secondary grounds by the use of wood molding.—W. H. K., Evanston, Ill.

BOOK REVIEWS.

"British Electrical Trades Directory and Handbook." Published by "The Electrician," 8 Bouverie Street, London, E. C. 4. Cloth; 1330 pages, 6½ by 9½ in. For sale by International Trade Press, Inc., Chicago. Price, $2.00.

The volume is prepared to supply information on all questions relative to the electrical industry that have a bearing on British affairs. The contents of the volume range from definitely technical to merely general matters so that it is valuable alike to the engineer, the contractor, and the dealer. The material in the volume, moreover, is gathered from all parts of the British realm and from such other countries as may be desirable to British engineers and contractors.

The volume is divided into two sections: namely, literary and directorial. The former section contains information about patents, designs, and trade-marks, domestic and foreign, about weights and measures, etc. The electric lighting acts and clauses regulating all phases of apparatus and practices occupy nearly 200 pages.

The directorial portion of the volume, which occupies nearly 900 pages, contains a classification of the electrical industry in Great Britain and its possessions. The classification of the industry in Britain is made alphabetically according to the name of individuals or companies and, again, according to the branch of industry. Classification of the industry in the colonies is made separately. The industry of the United States is not included in the volume. The volume, which is somewhat larger than the 1918 issue, will be of great value to the electrical industry not only in Great Britain and its colonies, but also to that in all other countries.

"Electricity and Magnetism for Engineers," by Harold Pender. Published by McGraw-Hill Book Co., Inc., New York City. Cloth; 200 pages (6 by 9 in.), 170 diagrams. For sale by International Trade Press, Inc., Chicago. Price, $2.00.

This is the second part of a treatise on Electricity and Magnetism for Engineers. Part I treats of Electric and magnetic Circuits, and the second part is devoted to Electrostatics and Alternating Currents. As the titles are not mutually exclusive, so we find that the treatment of alternating currents is not confined to Part II, but some phases of the subject are discussed in Part I.

While the treatment of electrostatics and alternating currents is theoretical, it is also from an engineering point of view, and the practical bearings of the principles are brought out by numerous problems and examples.

There are several interesting features of the text. The one that first impresses itself upon the attention of the reviewer is the scientific thoroughness of the discusions, and coupled with this is the care exercised in stating the limitaions of formulas. This last feature is especially valuable from a practical viewpoint. The statement of the limitations of formulas will save much confusion on the part of beginners, but it will do more than this. It will tend to develop in the student the power of discrimination and exactness.

Since the book is a continuation of Part I, the chapters are numbered consecutively throughout both volumes. The subdivisions of electricity and magneism treated in Vol. II are:

Electric Fields of Force, Electrostatic Capacity, Sine-wave Alternating Currents, Impedance and Admittance, Reactance and Susceptance, Effective Resistance and Effective Conductance, Polyphase Circuits, Symbolic Notation, and Non-sinusoidal Alternating Quantities.

The chapters on symbolic methods of solving alternating-current problems and on the analysis of alternating or non-sinusoidal waves will be found very useful in practice.

Any student who masters the principles explained in this text will have a most excellent foundation for the more technical studies of electrical engineering. The book should therefore be widely used by technical schools. C. M. JANSKY.

New Appliances

Mazda C-4 Lamp—Headlight Control Switch—New Cords —Berthold Washer—Willys Light—Marble-Card Machines

The White Mazda 50-Watt Lamp.

An important development in incandescent lamp manufacture is the "White Mazda" 50-watt lamp, or as it is also called the Mazda C-4 lamp. It was first briefly announced at the Atlantic City convention of the National Electric Light Association and further particulars have been made public in Bulletin No. 37 just issued by the Engineering Department of the National Lamp Works of General Electric Co., Nela Park, Cleveland, Ohio.

The new lamp is unique for several reasons. It has a milk-white smooth bulb which gives excellent diffusion of the light over its entire surface. It is of the gas-filled type, being the smallest lamp yet made of this type. It is a tipless lamp. The following facts are taken from the bulletin referred to:

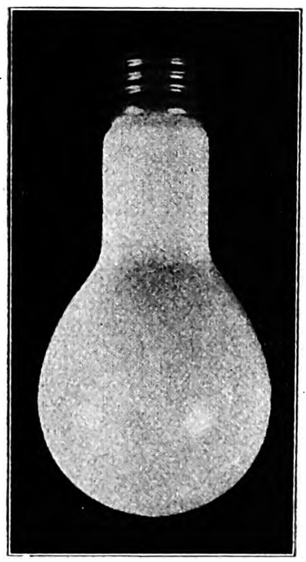
"The outstanding characteristic of this lamp is the pleasing softness of its light. The large volume of light which the small filament emits is diffused to the point where the bulb itself appears luminous. The brightness of the bulb is about 13 candles per sq. in. over the brightest square inch of area, which is, of course, far below that of the filament of a Mazda B lamp. The white Mazda lamp is made in the 50-watt size, and, notwithstanding the low brightness of the bulb, supplies more light than the 50-watt Mazda B lamp.

"It has been pointed out many times that glare (which, however defined, is ultimately light which hurts the eye) is to a considerable extent a matter of brightness contrast. The familiar illustration of automobile headlights, which glare at night but which are scarcely noticeable during the day, will be recalled. Because of the softness of its light, the white Mazda lamp can be used satisfactorily in locations where any other incandescent lamp unless frosted would be objectionably bright. Frosting the bulb has always proved an effective means of reducing the brightness of small incandescent lamps, but the practice has not been widely followed, largely because the frosted bulb collects dust and dirt more quickly than a clear bulb and is more difficult to clean. The bulb of the white Mazda lamp is smooth, and is as readily cleaned as a clear-glass bulb.

"There will, perhaps, be a tendency to use the white Mazda lamp without reflecting equipment because of the softness of its light. However, for most locations the bulb is still too bright to be used alone; moreover, it must be remembered that reducing glare is only one of the functions of a reflector. From the standpoint of effective distribution of the light generated, it is just as important that a good reflector be used with a white Mazda lamp as with any Mazda C lamp.

"Broadly, the field for the white Mazda lamp lies in the replacement of the smaller sizes of Mazda B lamps in existing reflector equipment. The effect produced by using white Mazda lamps in semi-indirect fixtures is particularly pleasing, for distinct shadows of the bowl edge and the bowl suspension, and all striations on the ceiling, are eliminated because of the large area from which the light comes. For the same reason, white Mazda lamps are also particularly desirable for portable lamps, where their use will eliminate the formation of grotesque, and frequently annoying shadows upon the walls or upon the pages of a book; fringe shadows, which are often very disagreeable, are eliminated.

In Table 1 are given the results of tests made to determine the effect of



White Mazda (or Mazda C-4) 50-Watt Lamp—Approximately One-Half Actual Size.

the diffusing bulb upon the output of lighting units. It will be noted that there is little difference in the absorption of any of the units tested when equipped respectively with Mazda B and with white Mazda lamps.

TABLE No. 1—DATA ON LIGHT OUTPUT.

Type of Unit.	Output in Per Cent of Bare-Lamp Output. Mazda B.	White Mazda.
Glass bowl, 6-in. diameter.	85.4	87.6
Glass bowl, 7-in. diameter.	84.8	86.1
Enclosing unit	77.5	76.4
Enameled-steel bowl	60.5	61.3

"With regard to the service which may be expected from white Mazda lamps, it may be said that laboratory tests indicate a satisfactory degree of ruggedness for home lighting, office lighting, and hotel and public building lighting, where these lamps will probably find their chief application. The low bulb brightness may result in white Mazda lamps, despite their higher wattage, being used to replace many smaller lamps used on extension cords for the inspection of machined interiors and similar places difficult to light with any general lighting system, and only trials under service conditions can establish what degree of rough handling in drop-cord service the white Mazda lamp will withstand.

"The white Mazda 50-watt lamp is made in the pear-shaped bulb, which is the shape used in Mazda C lamps. It will be noted from the illustration that the bulb is tipless. The lamp has about the same maximum dimensions as the 40 and 50-watt Mazda B lamps. No difficulty should be experienced in replacing Mazda B lamps in existing reflectors or shades."

Additional technical data are as follows: The lamps are made for voltages from 110 to 125; their lumen rating is 490, giving an efficiency of 9.8 lumens per watt. The bulb diameter is 2½ in. and the maximum over-all length is 5⅛ in. The base is medium screw size. The rated average life is 1000 hours; 50 is the standard package quantity.

The lamps are made by National Lamp Works of General Electric Co., Cleveland, Ohio; Edison Lamp Works of General Electric Co., Harrison, N. J.; and Westinghouse Lamp Co., New York City.

Ingenious New Locomotive-Headlight Switch Now Being Made.

High-speed railroad operation in the open country at night requires a very powerful locomotive headlight to insure safety. When nearing a train approaching on an adjoining track, a brilliant headlight confuses the other engineman, however. Also, when approaching signals the brilliant light of the headlight may cause confusion or inability to read the signal correctly.

Within cities a very bright headlight also causes blinding confusion and dangerous annoyance to pedestrians, teamsters and automobilists.

These conditions make it desirable to control the brightness of the headlight to a dim value when desired.

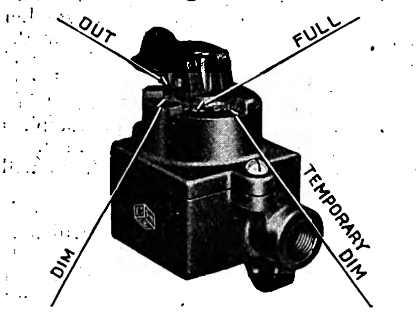
A new locomotive headlight switch has recently made its appearance. It has a number of features that will quickly appeal not only to the master mechanic but to the locomotive engineer.

This headlight switch is a complete, self-contained, dust-tight switch that will effectively take the place of a double-throw switch for dim and full light, and a momentary-contact switch for temporary dim light.

With an easy push the handle goes from "Off" to "Dim" and another slight push sends it to "Full." Going into "Dim" before going into "Full" gives the filament a chance to heat before coming to full glow, which means a longer life for lamps.

While passing another locomotive or for picking up signals, it is not necessary to bring the switch back to the "Permanent Dim" position. The engineer merely pushes the handle from "Full" to "Temporary Dim," holding it until he has passed the other train or the signals, when he releases the handle and the switch automatically snaps back to "Full."

If going through a yard or a city where the headlight must be dim, a slight lift of the handle brings the switch back to the "Permanent Dim" position.



Switch for Convenient Control of Locomotive Headlight Through Several Degrees of Intensity.

This handy little switch can be mounted at any place in the cab that is suitable. Its mechanism cannot get out of order. The internal spring and the stops on the cover insure proper location of the switch at the position desired and makes it impossible for the switch to stop between positions. This switch is a new product of the Crouse-Hinds Co., Syracuse, N. Y.

Belden New "Hard Usage" Portable Cord.

The Belden Manufacturing Co., Western avenue and Twenty-third street, Chicago, Ill., has developed a special type of portable cord, "Underwriters' PWp.," which has been exceedingly well received by the trade. This cord, while resembling the ordinary weatherproofed portable, has certain differences in construction that make it much more durable. Instead of the usual 1/64-in. wall of 10% rubber over the two conductors, there is a 1/32-in. wall of 20% (Beldenite) rubber. Then, in place of the ordinary soft cotton braid, there is a heavy twine used for the outside cover. The result is a cord which is exceptionally strong and which will stand exceedingly hard usage.

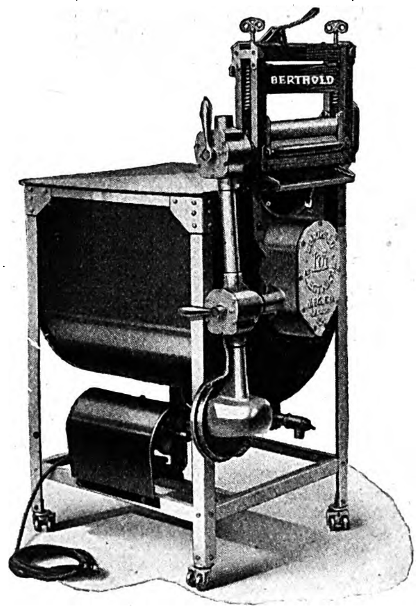
It has been found that when this cord is used for portable lamps, tools, etc., in garages, machine shops, locomotive repair shops and such places where the ordinary cord is subjected to extraordinary wear, it has a life which compares very favorably with armored cable and has the advantage of being much more flexible.

Berthold Electric Washing Machine.

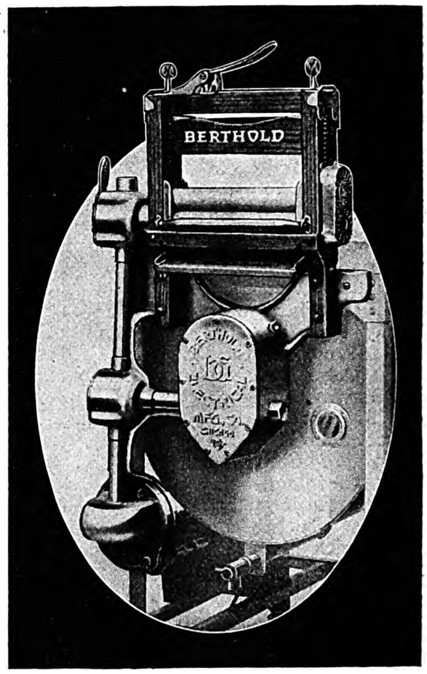
The increasing demand for electric washing machines of the last few years is stimulating the production of new devices of this kind, and among these one of special interest is the washer recently placed on the market by the Berthold Electrical Manufacturing Co., 127 South Green street, Chicago, Ill. This machine has been developed by E. E. and G. W. Berthold, who have been connected with the Electric Apparatus Co. for about 11 years, and their new design incorporates their experience with various types of appliances.

The new Berthold washer was designed with three principal ideas in mind. These were: Ruggedness and durability of construction, safety in operation, and efficiency in service. The accompanying illustration shows that the machine consists almost exclusively of metal, the only exception being a few parts of the wringer. The framework consists of angle irons well braced and secured together. The mechanism (including shafting, gears and other moving parts) is entirely inclosed in a one-piece casting. This is done for a number of reasons. First, it prevents these parts from getting out of order or alinement; it safeguards the operator or anyone else from having her or his clothing entangled in exposed gears or other moving machinery; finally it permits the gears, bearings and other running parts to be operated in oil just like the transmission of an automobile. This latter provision dispenses with the need for grease or oil cups and positively prevents any oil from oozing out of bearings or other places so as to stain the clothes being washed or the dress of the operator. It also provides the most perfect lubrication so as to insure very efficient operation and, therefore, low power consumption. The matter of safety, referred to above, has been given special consideration because exposed moving machinery around a washer has been found dangerous not only to the operator but to children who frequently are playing about the laundry while their mother is taking care of her washing. The complete inclosure of the machinery also insures very quiet running.

The machine operates on the reversing cylinder principle. The cylinder makes 5½ revolutions and then automatically reverses, repeating this cycle without attention. The capacity of the cylinder is eight large sheets or their equivalent. The cylinder is made in two types, either of solid copper or of galvanized steel. Simplicity of control is secured by providing only two operating levers, one of which starts and stops the washing cylinder, and the other starts and stops the wringer in either direction. The washer and wringer may be operated independently or together at the same time. The wringer is of the highest quality obtainable and is provided with a safety release to prevent damage to buttons or other delicate parts of the clothes in case a batch should become choked in the rolls. A high-grade motor is used; it is protected from splashing water as shown. The machine can be easily moved about since it is provided with the easy running casters. A sheet-metal top permits using the top as a table. Every detail in its construction and assembly is taken care of to insure perfect operation and freedom from trouble.



The Berthold Electric Washer with All Gears, Shafts and Other Moving Parts Enclosed in a One-Piece Casting.



Enlarged View of Berthold Washer Showing the Large One-Piece Enclosing Casting.

John N. Willys to Market New Electric Light and Power Plant.

A modern electric lighting and power plant for farms, rural schools, churches, suburban homes, yachts, etc., is to be manufactured by one of the John N. Willys companies, the Electric Auto-Lite Corporation, of Toledo, Ohio. The new outfit will be known as "Willys Light." It will be marketed by the Willys Light Division of the Electric Auto-Light Corp. through distributors and dealers. The formation of the sales organization is now under way; it will extend throughout the United States and eventually throughout the world.

The new plant is claimed to be the most complete that has yet been placed on the market. It is operated by a

Willys-Knight sleeve-valve engine which is known for its simplicity of operation and its quietness. The engine has been developed to such an extent that it requires practically no attention and is so simple that a child can operate it, according to those who have observed it.

The complete plant consists of a Willys-Knight engine, a direct-connected generator, a simple control box and a storage battery. The engine burns kerosene at approximately one-half the cost of gasoline. It is air-cooled, self-cranking, self-running, and self-stopping. The control is semi-automatic.

Noisy poppet valves are eliminated in the Willys-Knight engine. In their place are two cylindrical sleeves, one within the other, which glide silently up and down between the piston and the cylinder wall. The long ports in these sleeves register with each other and with the ports in the cylinder wall at the proper intervals, forming large and direct passages for the intake and exhaust gases. This engine is said to improve with use; carbon, instead of decreasing its efficiency, increases it.

The Willys Light generator is shunt-wound and designed for 32 volts. Its capacity is 750 watts. The armature of the generator, the engine flywheel and crankshaft are constructed in practically one piece, thus eliminating separate generator bearings and reducing friction.

The battery consists of 16 lead type cells with 9 plates to the cell. These are enclosed in sealed glass jars. They have a capacity of 160 ampere-hours.

The quality and dependability of the new equipment is assured by the fact that John N. Willys would not have permitted it to take his name until the outfit had been proved out thoroughly. With the Electric Auto-Lite Corp., a company long engaged in the manufacture of electric lighting and starting systems for automobiles, producing it, there is assurance as to the high standards of manufacture that will enter into its construction and of service in its distribution.

The new lighting outfit is adapted to a large number of uses. In addition to its general utility on the farm, it is available for isolated cotton gins, lumber and construction camps, oil and gas-pumping stations, mines, outlying stores, garages, dairies, telephone exchanges in smaller towns, and railroad stations. It also may be utilized for remotely located hospitals, fishing and hunting clubs, country homes, for street, store and home lighting in very small towns, for small theaters, military camps, and in summer resorts and cottages.

New Line of Commutating-Pole Motors and Generators.

Direct-current generators and motors have been manufactured over 35 years, but improvements in construction are still being made as is shown in a new line of these machines developed and manufactured by the Marble-Card Electric Co., Gladstone, Mich. These motors and generators are designed to incorporate some 26 years of fruitful experience in designing direct-current machines by John F. Card, during which time over 40,000 machines have been built after his designs. Every detail of the new line of these motors and generators has been carefully studied and the final features selected to combine in the complete design the highest standards of construction and operation. The machines are liberally proportioned and conservatively rated, and are therefore especially adapted for exacting service.

All machines are of the commutating-pole type with as many commutating as main poles; these insure perfect commutation at all times and eliminate the need for shifting the brush position. The field frames are made of high-grade cast steel in one piece, including the feet. All poles are securely attached with two lag screws; the main poles are laminated and assembled under hydraulic pressure. All bearings in standard machines are of the best ball-bearing type of generous size to withstand all possible strains; these ball bearings assure low losses and therefore high efficiency and also permit a shorter shaft length. The bearing brackets are designed so that the machines may be mounted on floor or ceiling without any change whatever. If mounted on a side wall or column it is necessary to rotate the outer bearing closures only to bring the drain plugs into the vertical plane. The sliding base is of heavy construction and has a three-point bearing and improved belt-tightening device within the base.

The brush holders are of very simple and effective design, having only two moving parts and no spring adjustment, the tension of the spring being set at the factory to the correct value. The commutators are of rolled copper with the mica undercut; they are of large size. All armature coils are form-wound, dipped and baked. Field coils are wound on collapsible forms, covered with many layers of oiled muslin, taped, dipped and baked, and finally varnished. Commutating-pole coils are wound directly on the poles after these are first well insulated.

These machines are made in the two-pole type in the smaller sizes (7.5 hp. and smaller) and of the four-pole type for 7.5 hp. and larger sizes. The standard speeds are 575, 850, 1150 and 1700 r. p. m. Standard motors are made with either shunt or compound field windings. All terminals are brought out to the terminal board so that it is very easy to change motor direction. All the machines are especially well ventilated and are quiet in operation. They are well suited for a variety of purposes and the motors have been found especially adapted for electric freight and passenger elevators. The generators have been found exceptionally well suited for low-voltage farm lighting plants and motion-picture service.

Portable Suspension Cord for Gas-Filled Lamps.

The Belden Manufacturing Co., Chicago, Ill., has developed and placed on the market a cord especially adapted for pendent lighting units using gas-filled lamps. This cord, which has been approved by the National Board of Fire Underwriters, is made in both the types "P" and "PS" portable, and consists of the ordinary conductor, rubber-covered, and then covered with a heavy braiding or serving of asbestos. The remainder of the construction, that is, the rubber outer wall and braid over-all, is the same as in the ordinary portable.

This type of construction has been developed as a result of the insistent demand of the trade that the portable cord for pendent purposes be so manufactured as to withstand the very high temperature of the commercial gas-filled lamps, and for this purpose it has proved itself to be excellently adapted.

Trade Activities

Eureka Vacuum Cleaner Erects Large Modern Factory—C. T. Coe Company Takes Over Hafer Interests—Literature

Edison Electric Appliance Co., Hotpoint Division, Chicago, sustained a heavy loss when fire practically destroyed the storage house at 2214-30 Ogden avenue on Sunday, July 6. W. H. Casper, superintendent, places the loss at $75,000.

The Edison Storage Battery Co. announces the removal of its district office in Pittsburgh, Pa., to Room 431 Union Arcade building. The removal has been made necessary by the tremendous increase in the volume of business handled through this office. The new location provides better facilities and more commodious quarters.

P. W. Miller Co., 735 Andrus building, Minneapolis, Minn., has entered the field as an electrical jobber in 32-volt accessories. The company has just obtained a contract from the Electric Auto-Lite Corp., Toledo, Ohio, for the Willys farm lighting plants for the state of Minnesota, part of North Dakota, Wisconsin and Montana, and anticipates a large volume of business in this territory.

Jeannin Electric Co., Columbus, Ohio, has entered the electrical field, having recently been incorporated with an authorized capital of $150,000 to engage in the manufacture of electric motors. C. H. Clement, formerly with the Bock Bearing Co., is president and treasurer of the concern; H. W. Jeannin, vice-president, and Morton C. Seeley, secretary. The factory will be located at 110 11th street and will have an estimated output of 100 small motors monthly.

The Wallace Barnes Co., Bristol, Conn., has issued Booklet No. 7 descriptive of "Barnes-made" springs, screw machine products, cold rolled steel and wire, washers, stampings, etc. The booklet is well illustrated and contains a number of diagrams and tables showing decimal equivalents of wire, gauges, weight of cold drawn steel, weight of cold rolled strip steel and weight of wire; also specifications to be used in ordering compression and extension wire springs, and table of capacities of compression and extension wire springs.

Contra-Pole Electric Co., 1227 Prospect place, Brooklyn, N. Y., recently incorporated with a capital stock of $100,000, is manufacturing electro-therapeutic apparatus. Mortimer E. Freid, formerly affiliated with the purchasing department of the Signal Corps of the Army, is president of the company; Julien de Beaumont, consulting electrical engineer, first vice-president; Julius Heinecke, general manager of Liebig Extract Co., second vice-president; Samuel T. Siegel, attorney, 165 Broadway, New York, secretary.

The Aberthaw Construction Co., Boston, Mass., has opened a permanent office in Atlanta, Ga., which will be under the direction of N. McL. Sage.

The Electric Furnace Construction Co., Finance building, Philadedphia, reports the receipt of an order for a one-ton Greaves-Etchells electric furnace from the Sullivan Machinery Co., Claremont, N. H.; also an order for a furnace for the manufacture of coinage bronze from the Imperial Japanese mint, Osaka.

F. I. Hutchinson, mechanical engineer, founder of the Heating & Power Equipment Co., Milwaukee, Wis., has severed his connection with the company to engage in business for himself. He has opened offices at 1226 First National Bank building, Milwaukee, as a consulting and designing engineer of heating and power plants, specializing in central-station installations.

J. H. Honig, Antofagasta, Chile, S. A.; announces the opening of an office at Latorre 446-448, which will give representation to American manufacturers who desire a connection in northern Chile. Mr. Honig has been engaged in this line of business for many years and until recently was manager of the Chile Trading Co., of Antofagasta. He will be pleased to hear from any manufacturers desiring representation in the territory mentioned.

Elvin Mechanical Stoker Co., 30 Church street, New York, has issued an illustrated folder describing the Elvin mechanical stoker for use on locomotives. Several advantages of the stoker are that its operations are wholly mechanical, that it regulates automatically the amount and distribution of the coal, and that it prevents the entrance of cold air into the fire box. An installation of the stoker on an Eric locomotive shows that the economy of the mechanical stoker is as great as if not greater than that of hand firing.

C. T. Coe Co., Chambersburg, Pa., engineer and combustion expert, owing to the greatly increased demand for the Coe grate and Coe turbine blower, has again found it necessary to extend its manufacturing facilities. The company has, therefore, purchased the plant, patents and equipment of the Hafer Foundry & Machine Co., Chambersburg, Pa., which since 1906 has been engaged in the manufacture of the Hafer double-shift rocking grate and Little Giant soot blower for boiler tubes. The plant has a foundry with a 12-ton daily capacity, brass foundry, machine shop, pattern shop, blacksmith shop, all of which has been added to the equipment of the Coe company, resulting in a more complete organization, better able than ever to supply the needs of the trade. The combined patterns of the two plants include all standard grates, arch plates, etc., so that the company is now prepared to manufacture a most complete line of boiler room equipment. The Coe organization specializes in everything that pertains to combustion and its competent staff of engineers is ready to solve problems relating to this important subject.

Central Electric Co., 316-326 South Wells street, Chicago, is sending out a new combined price list and catalog of new material designated as No. 39-A. Some 80 pages are devoted to a listing of net prices and discounts applicable to general catalog No. 39. The remaining pages carry a list of devices either new or redesigned, consisting of marine lighting and signaling appartus, industrial signals, receptacles and plugs, transformer and junction cutouts, switches, sockets, switch plates, lighting units, lamps, transformers, etc.

Acme Lighting Fixture Co. has taken over the plant of the Acme Gas & Electric Co., Inc., and will continue operations at 132-136 West 14th street, New York. The former company manufactures a complete line of electric and combination lighting fixtures, lamps and accessories, and has added to its staff competent designers of lighting fixtures in order to furnish special as well as staple designs of lighting fixtures and accessories. The company has greatly increased its facilities and is now in a position to meet the requirements of the trade. The present plant provides facilities for the production of designs of elaborate decoration, durable construction and lasting finish, embodying the newest ideas in interior and commercial decorative schemes.

American Electric Fusion Co., Warren, Ohio, is the name of a recently organized concern with an authorized capital of $25,000 to manufacture electrical apparatus for heating, melting and fusing. The company has acquired a two-story building which will be used as its plant. For the present the company will devote its attention to the production of a new type of an alternating current arc welder, which will be built in sectional form, the lower section to contain equipment for transforming standard voltages, 440, 220 or other commercial circuits, down to 60 volts. The upper section will contain the stabilizing and regulating apparatus. Fred P. McBerty, president of the Federal Machine & Welder Co., is president of the new organization; E. J. Henke, vice-president, and Z. A. McBerty, secretary and treasurer.

Roller-Smith Co., 223 Broadway, New York, has issued an illustrated bulletin (No. 140), describing a new device known as the "Handy" auto type volt-ammeter. This device has six ranges and provides a means of quickly and accurately making all the different tests which are involved in electric lighting and starting systems of automobiles. The entire outfit is simple, sturdy, compact, light and built for the hardest kind of service. "Handy" instruments are also furnished in a complete line of ammeters, milli-ammeters, voltmeters, milli-voltmeters and volt-ammeters.

The Central Station Steam Co., Detroit, Mich., announces the opening of a branch office at 902 First National Bank building, Chicago, with W. K. Abernethy, formerly manager of the Minneapolis office, in charge. All business in Illinois, Iowa, Nebraska, Missouri, Indiana and Ohio will be handled from the Chicago branch.

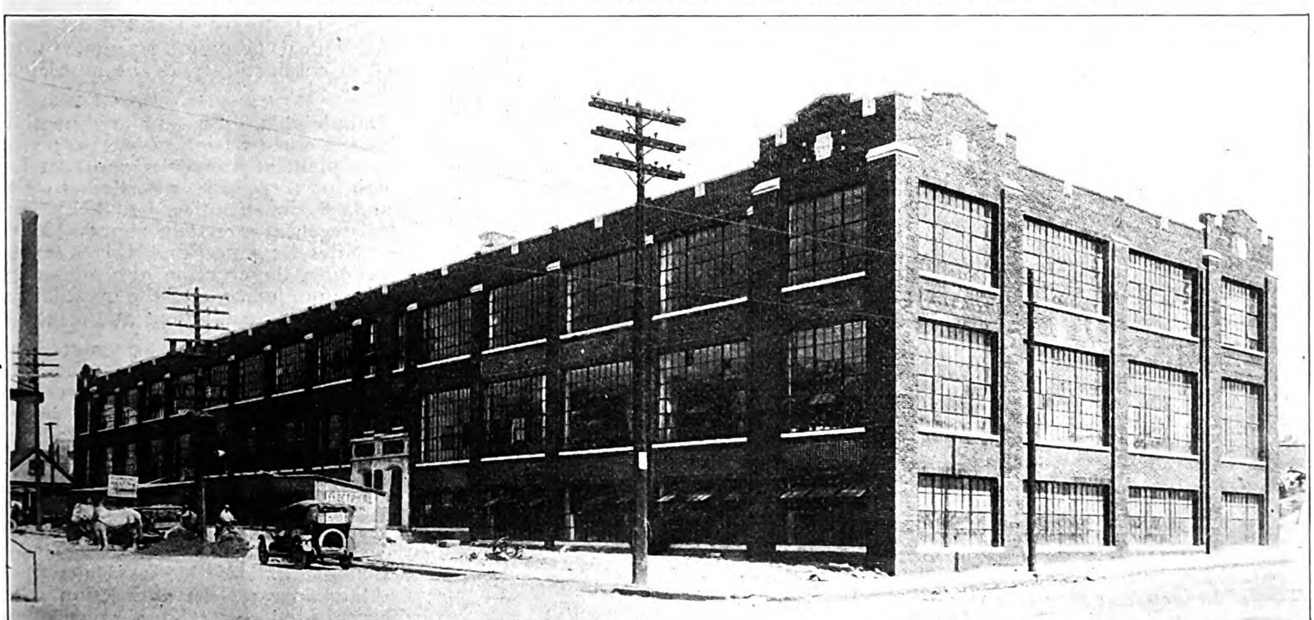
The Wellman-Seaver-Morgan Co., Cleveland, Ohio, has prepared Bulletin 22, which contains valuable engineering charts on shafts. The bulletin is devoted to three large charts giving the relations in any shaft between power, shaft diameter, torsional stress and speed, and contains several examples showing the method of using the charts. By means of these charts it is possible to instantly solve any one of four problems: (1) Given the power, speed and allowable torsional stress, to find the shaft diameter; (2) given the shaft diameter, power and speed, to find the torsional stress; (3) given the power, torsional stress and diameter, to find the speed; (4) given the speed, torsional stress and diameter, to find the power. These charts have been prepared by one of the company's engineers. Copies of the publication will be sent to all engineers and draftsmen free of charge upon request.

The Thistle Manufacturing Co. of Chicago, manufacturer of the "Up 2 Date" home electric washer, recently moved into its new factory, located on Armitage avenue, between Major and Mango avenues. The constantly increasing popularity and unusual demand for this washer made it necessary for the company to seek larger quarters, but as it is now able to produce twice the number of machines turned out heretofore, it will probably be able to keep up with the demand. The new factory consists of two floors of a large building, giving the company more than twice its former floor space. The building faces the main line of the Chicago, Milwaukee & St. Paul railroad at the Galewood yards, at which point are located the switch yards of the railway company. From this point all loaded and unloaded cars running over the Milwaukee line are handled. This location gives the Thistle company excellent shipping facilities. In addition it has equipped the new factory with the most modern machinery, giving it every facility for quick and efficient work.

Eureka Vacuum Cleaner Co., Detroit, Mich., has erected a new plant which it claims is the largest exclusive vacuum cleaner factory in the world. The building is a three-story structure and covers an area of over 19,000 sq. ft. Over 60,000 ft. of floor space is provided and the plant is equipped with a tremendous amount of up-to-date machinery which will make possible the production of 1000 electric cleaners per day. Since the war the influx of orders for the Eureka cleaner has been so great as to render the company's facilities entirely inadequate to meet the demand, and at the present writing orders for 12,000 machines remain unfilled. The building of this large factory is indicative of the optimistic view the Eureka company has of the future, and also signifies the success and stability of the vacuum cleaner industry as well as the remarkable success which has attended the Eureka cleaner. The company is also erecting in the heart of Detroit a five-story office building which will be used as the general offices of the Eureka Vacuum Cleaner Co. exclusively. It is modern in every respect and affords ample space to handle a business which is rapidly expanding. The company is about to launch the largest national publicity campaign in its history to be of distinct aid to its many distributors throughout the country.

Fort Wayne Engineering & Manufacturing Co. has prepared for the dealers' bulletin file a catalog of the Paul water systems, bringing together under one cover a number of bulletins which have been issued from time to time. It contains descriptions, diagrams and list prices of the popular combinations of pumps and systems to meet most requirements within their limits. The company has also issued Bulletin 5005, superseding Bulletin 4096, describing Paul electric pumps and water systems using 32-volt direct current. Installation examples of these systems for the farm and country home are given as well as detailed descriptions of the various pumps and systems manufactured by this company.

Mercury Manufacturing Co., 4119 South Halsted street, Chicago, has issued a new publication entitled "The Trackless Train" treating of the Mercury method of internal transportation, which will attract widespread attention and prove very interesting to users and prospective users of industrial tractors. It discusses the development, use, construction and function, economy and flexibility of this system of industrial haulage and sets forth 15 pertinent reasons why the "trackless train" should be adopted. The bulletin is replete with illustrations of typical installations and the economy affected by the Mercury tractor is manifested by its representation in practically every industry. This method of internal transportation is based upon the sound principle that transportation efficiency requires the handling of material with the smallest possible number of men and the smallest possible number of power units. It is adaptable to every type of industry, and practically to every haulage problem within each. The advantages of this method of industrial haulage may be briefly summarized as follows: Installation economy, operating economy, flexibility, maximum operating efficiency, ease of operation and safety.



New Factory of the Eureka Vacuum Cleaner Co., Detroit, Mich.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Portland, Me.—Fire recently damaged the building of the Cumberland County Light & Power Co. It is understood that the company is planning for immediate repairs.

Rutland, Vt. — Rutland Railway, Light & Power Co. has recently been awarded a contract by the Wallingford Manufacturing Co., Wallingford, for furnishing additional power to the amount of about 100 hp. for the operation of a new saw and planing mill at its works.

Springfield, Vt.—Colonial Power & Light Co. is making rapid progress on the construction of the new electric substation, and it is expected that the work will be completed at an early date.

Quincy, Mass.—Fire recently destroyed the coaling station at the plant of the Quincy Electric Light & Power Co., with loss estimated at $15,000.

Hartford, Conn.—Case & Marshall, Inc., has awarded a contract to the J. H. Grozier Co., 721 Main street, for the construction of a new boiler plant at its works in the Burnside section. The structure is estimated to cost $10,000.

Binghamton, N. Y.—In connection with the installation of large quantities of electrical equipment at the new plant of the Achilles Rubber & Tire Co., work is now under way on the installation of a 150-kw. motor generator set. Power for operation will be furnished by the Binghamton Light, Heat & Power Co.

Binghamton, N. Y.—Plans are under consideration by the Board of Contract and Supply for the construction of a new municipal lighting plant to be located on Conklin avenue. W. E. Weller is city engineer.

Brooklyn, N. Y.—R. H. Comey Co., Inc., 73 19th street, is planning for alterations and improvements in the boiler plant at its works, to facilitate operations.

Brooklyn, N, Y.—Kayenn Manufacturing Co., manufacturer of electrical specialities, has completed negotiations for the leasing of the entire third floor of the building at 291-3 Adams street, for a new establishment.

Manhasset, L. I., N. Y.—Town Board, North Hempstead, is understood to be considering plans for the extension of its street lighting system on Station Road, at Great Neck Station to connect at Kensington.

New York, N. Y.—Long Acre Hardware & Electric Co., 806 Eighth avenue, has filed notice with the Secretary of State of an increase in its capital from $10 000 to $20,000, to provide for general business expansion.

New York, N. Y.—New York Edison Co., Irving Place and 15th street, has recently been awarded a contract for furnishing electric energy for the operation of the plant of the Auto-Strop Safety Razor Co., 656 First avenue. The works require 500 lamps for illumination, and 300 hp. in motors for manufacturing, as well as power for an electrically heated furnace for tempering steel blades. The company has also received a contract for furnishing power to the Union Trust building, 80 Broadway, and the Electrical Exchange, 136 Liberty street, having lighting installations of 2000 and 1000 lights, respectively.

New York, N. Y.—Belzo Electric Motor Co. has filed notice with the Secretary of State of a change in name to the Zobell Electric Motor Co.

New York, N. Y.—Alpha Electric Co., Inc., 116 West 29th street, has leased property at 151-55 West 30th street, aggregating about 22,500 sq. ft. for a new plant.

New York, N. Y.—Manhattan Railway Co. has had plans prepared for alterations and improvements in its one-story repair shop at Lexington avenue and 98th street. The work is estimated to cost about $50,000.

Syracuse, N. Y.—W. S. Hoffman, 329 Tuckel street, is having plans prepared for the construction of a new one-story foundry and power plant, about 50x200 ft., the entire work being estimated to cost $50,000. Contract for construction has been awarded to Dawson Brothers, Union building.

Califon, N. J. — Califon Electric Light & Power Co. has entered into a contract with the Hackettstown Electric Light Co. whereby the latter concern will supply electric service. The company will also issue capital stock to the amount of $10,000 for expansion. Permission for the stock issue has been granted by the Board of Public Utility Commissioners.

Dover, N. J.—New Jersey Power & Light Co. is making rapid progress on the installation of a new pumping station in the local plant. It is understood the station will be utilized for condensing purposes during dry seasons.

East Orange, N. J.—General Electric Co., Harrison, has filed plans for the construction of a two-story brick addition to its works on North 18th street, to cost about $40,000.

Jersey City, N. J.—Eastern States Refrigerating Co., 147 16th street, has filed plans for the construction of a seven-story concrete addition to its works on 15th street, to cost about $125,000.

Newark, N. J.—M. & L. Electric Co. has filed notice of organization to operate in a general electrical contracting capacity at 470 Warren street. Raymond Miller, 263 Bloomfield avenue, Verona, and Carl M. Lindheimer, 712 Ocean avenue, Jersey City, head the company.

Newark, N. J.—Weston Electrical Instrumental Co., 4 Weston avenue, has had plans prepared for the erection of a new addition to its plant. The structure is estimated to cost $7500.

Newark, N. J.—Terminal Electric Co. has filed notice of organization to operate a general electrical contracting establishment at 94 New street. Robert and M. M. Goldberg, 301 Belmont avenue, head the company.

Trenton, N. J.—Considerable electrical equipment of various kinds will be required in connection with the construction of the proposed hospital buildings to be erected by the state, contracts for which were awarded to the Standard Construction Co., Sansom street, Philadelphia, Pa., at a cost of about $300,000.

Trenton, N. J.—Trenton & Mercer County Traction Corp. has commenced work on the extension of its traction system from Bridge street to the municipal dock. E. J. Peartree is general manager.

Trenton, N. J.—A building permit has been taken out by the Hutchinson Storage Battery Co., Warren street, for the construction of new additions to its plant, to provide for increased capacity. The structures will be one and two stories, brick and steel, and are estimated to cost $16,500.

Westmont, N. J.—Township Committee has been granted permission by the State Board of Health to erect a new local pumping station, to be used in connection with the municipal sewage plant.

Philadelphia, Pa.—In connection with the construction of the proposed power plant at its works, contract for which was recently awarded to the Standard Construction Co., 1713 Sansom street, at a cost of about $10,000, the Niles-Bement-Pond Co. has arranged for the erection of a one-story brick pump house, and the installation of new boiler equipment at the plant.

Philadelphia, Pa. — Contract has been awarded by the Surpass Leather Co., Ninth and Westmoreland streets, for the construction of a new boiler plant at its works, estimated to cost $6000.

Philadelphia, Pa.—Plans have been prepared by the Griffon Co., Adams avenue and Wingohocking street, for the erection of a new three-story plant, about 4445 ft., at Unity and Oakland streets. In connection with the proposed structure, a boiler plant will be erected, the entire project being estimated to cost $104,000.

Pittsburgh, Pa.—Atlantic Refining Co. has filed plans for the erection of a one-story brick and concrete boiler plant to be located on Butler street, near 57th street, estimated to cost $25,000.

Elkton, Md.—Atlas Powder Co., Wilmington, Del., has disposed of its power plant at Perry Point to new interests. The company will be incorporated with extensive operating capital, and will operate the plant for local service. Electric energy will be furnished to Perryville, Port Deposit and Havre de Grace, with a system of distributing lines through this district. The new company is also planning for the erection of an ice manufacturing plant and mechanical laundry works, both to be electrically operated.

Seat Pleasant, Md.—The council is preparing to establish municipal lights. Address Severing Grobstad.

Clifton Forge, Va.—Notice has been filed with the Secretary of State by the Western Virginia Power Co. of an increase in its capital from $1,000,000 to $1,250,000, to provide for general expansion. W. G. Matthews is president; and A. C. Ford is secretary.

Bowman, Ga.—Bonds have been voted for issuance of municipal bonds for establishing an electric light plant.

Springfield, Ga.—The city contemplates the installation of an electric light plant. Address the mayor.

Unadilla, Ga.—The city will install an electric light plant.

Miami, Fla.—Miami Beach Electric Co., Carl G. Fisher and associates, was voted a franchise for operating an electric railway and light and power plants in Miami Beach.

NORTH CENTRAL STATES.

Canton, Ohio.—George Eastman, 401 Daily News building, has prepared plans and will let contracts for a $75,000 hotel to be erected here. The specifications include electric machinery.

Cincinnati, Ohio.—An ordinance has passed the council authorizing a bond issue of $22,000 to repair the city hall and to make the necessary changes in the wiring system to permit the lighting of the building by the Union Gas & Electric Co. Petitions were filed with the council to extend the boulevard lighting system on Race street from 12th to McMicken avenue and on Colerain avenue from Central to Millcreek bridge.

Mansfield, Ohio.—Mansfield Sheet & Tin Plate Co. will erect a $1,000,000 addition to its steel plant. When the new plant is completed the company will have a complete unit in the steel industry, permitting it to take ore through its several processes and turn out the finished plate.

Columbus, Ind.—City will vote Aug. 7 on the question of a $60,000 bond issue for the erection of a gymnasium.

Indianapolis, Ind.—Architect W. L. Jungclaus, 822 Massachusetts avenue, has prepared plans for a $10,000 power house to be erected by the G. & J. Tire Co. The building will be of brick construction, steam heated, plumbing, electric lighting.

DATES AHEAD.

National Council of Lighting Fixture Manufacturers. Midsummer convention, Cleveland, Ohio, Aug. 5 and 6. Secretary-treasurer, Charles H. Hofrichter, 8410 Lake avenue, Cleveland, Ohio.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 19-21. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston block, Seattle.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual Convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26, 1919. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Logansport, Ind.—A new turbo-generator with a capacity of 200,000 voltage and weighing 75,000 lb., for use in the local electric light plant, has been installed at a cost of $25,000.

Chicago, Ill.—Grip Nut Co. has acquired a tract of about 250,000 sq. ft., on which it proposes to erect a large new plant. It will be one of the most modern in the country, will have traveling cranes extending the full length of the building and over the switch tracks. It is stated the building and ground will represent an investment of about $500,000.

DeKalb, Ill.—DeKalb-Sycamore Electric Co. is erecting cooling tower 75 ft. in height.

Urbana, Ill.—Board of local improvements has ordered the installation of 60 ornamental lamp standards on West Green street, at a cost of $6300. The board is also considering the installation of similar standards over the entire southwestern part of the city, adjacent to the University of Illinois. Address J. E. Smith, mayor and president of the board.

Villa Grove, Ill.—The failure of the Central Illinois Public Service Co. to furnish power several days the past weeks has started a movement to establish municipal lights. Address village clerk.

Lansing, Mich.—Architect O. E. Eckhart, City Hall, has prepared plans for extension to be made to the electric light plant. $300,000 will be expended, specifications including extension to electric light plant, steam heating, plumbing, power plant, electrical equipment. Contracts will be let by city clerk.

Black River Falls, Wis.—Architects Mead & Seastone have prepared plans for power plant to be erected by the city. Estimated cost $25,000. The power plant will be erected and engine dynamos, electric machinery purchased.

Milwaukee, Wis.—Permit was granted to the Electric Co., to erect a substation at 27th avenue and Burham street.

Neenah, Wis.—The council has decided to enter into a new lighting contract with the Wisconsin Traction Light, Heat & Power Co. The contract will provide for a larger number of lamps in the business district and less powerful ones in the outlying districts.

Superior, Wis.—The lighting system commission will petition for new white way in East End, Superior.

Wells, Minn.—City council is considering the construction of an electric power plant and distribution system and concrete reservoir. Engineer C. L. Pillsbury, Metropolitan building, Minneapolis.

Bloomfield, Iowa.—Citizens authorized officials to rebuild and repair municipal electric light and power plant. Address E. Z. Morrow, city clerk.

Ferguson, Iowa.—The question of establishing municipal lights will be submitted to vote. J. R. Finders, city clerk.

Humboldt, Iowa.—Northern Gas & Electric Co. contemplates extending its electric transmission lines from Ruthven to Lost Island Park.

Spencer, Iowa.—Spencer's municipal electric light and power plant will furnish electricity for power and lighting to farmers and several towns.

Butler, Mo.—Improvements for the electric light and water plant are contemplated.

Carrollton, Mo.—Harry A. Spradling and George A. Allen have purchased a substantial interest in the water, light and transit company. Mr. Spradling has been appointed manager and superintendent of the plant. The work of improving the plant is being rushed to completion. A 500-kw. engine and generator will also be installed to more than double the present capacity of the plant.

Edina, Mo.—Special reports have been prepared by experts on the proposition of placing a value on the light and ice plant. Improvements are also contemplated.

St. Joseph, Mo.—A new 10,000-kw. turbine with surface condenser is being installed in the plant of the St. Joseph Railway, Light, Heat & Power Co. The new equipment also includes two 1000-hp. boilers. G. W. Saathoff is the engineer in charge of the work.

Arlington, Kans.—Election will be held Aug. 1 to vote $20,000 in bonds for the purpose of purchasing, constructing and extending works for supplying the city with electric current. W. P. Barley, city clerk.

Elkhart, Kans.—Election to vote $60,000 additional bonds for the extension of the city water and electric light plant carried. It is planned to raze the old power house and erect a much larger building in which will be installed an elaborate two-unit plant giving 24-hour service.

Hutchinson, Kans.—Elections are to be held at Arlington, Langdon and Turon to vote the necessary bonds for the building of transmission lines from Hutchinson.

Kansas City, Kans.—The Kansas City commissioners awarded the contract for generators for the municipal electric light plant to the Westinghouse Electric & Manufacturing Co. The cost of the generators will be about $232,000 and the contract calls for delivery in 90 days. Contracts for other machinery, boilers, poles, and necessary equipment have been awarded. The addition will double the capacity of the present plant.

Liberal, Kans.—A resolution has passed ordering the installation of a white way. The new street lighting system will extend about three-quarters of a mile.

Ness City, Kans.—Another engine and generator are needed for the light plant. These will probably be purchased in the near future.

Partridge, Kans.—Election will be held Aug. 1 to vote $20,000 in bonds for the erection of an electric transmission line and power plant by which that town can get current from Hutchinson.

Wichita, Kans. — Kansas Gas & Electric Co. will build a transmission line ten miles west of the city.

Woodston, Kans.—Election to vote $13,000 in bonds for the purpose of buying and improving the light and power plant carried.

Antler, Neb.—At a special meeting city council decided to enlarge the lighting capacity of the city electric light system. Address town clerk.

Hickman, Neb.—Plans being made by Grant, Fulton & Letton, Bankers' Life building, for an electric transmission line from Lincoln to Hickman and an electric distributing system to be voted.

Oshkosh, Neb.—Bond issue of $9750 for construction and equipment of lighting system to be voted. G. M. Robinson, clerk.

SOUTH CENTRAL STATES.

Springfield, Ky.—Plans are being arranged by the Springfield Water & Electric Co. for the installation of a quantity of new equipment at its plant, including alternators, engines, panel switchboards, etc. It is understood that the company is planning to convert the plant to the alternating current system.

Jackson, Miss.—The light and power plants, gas plant and other properties of Jackson Light & Traction Co., were purchased by M. H. Grossman, Milwaukee, Wis., representing the bond holders. The plants will be improved.

Meridian, Miss.—Board of Managers of the local Masonic Home is considering plans for the installation of a new electric lighting plant. E. J. Martin is superintendent.

Merigold, Miss.—Sage Brothers & Jones Construction Co., Memphis, Tenn., is erecting a school building. The electrical work on this contract will amount to $1300. M. M. Alsop, Randolph building, Memphis, Tenn., is the architect.

Lamar, Ark.—The City Council has given the Commonwealth Public Service Co. of Fort Smith a franchise and has entered into a contract whereby the latter company will furnish electric power for lighting and other purposes. The company will extend its main line from Jamestown to Lamar.

Marvell, Ark.—Marvell Light & Ice Co. has increased its capital stock from $20,000 to $40,000. A. V. Newman is president.

New Orleans, La.—Plans are being arranged by the Board of Managers of the Charity Hospital, for the installation of a new underground system to be used for the furnishing of electric lighting to about twenty buildings at the institution. Construction has been completed on the power house, and work will soon be commenced on the installation of the necessary equipment, including 300-kw., direct-connected, 3-wire generators, steam engines, motors, etc. The entire work is estimated to cost $90,000. A. Wyndham Lewin, 335 Carondelet street, is consulting engineer.

Comanche, Okla.—Election to vote $35,000 for improving the electric light plant, carried recently.

Gotebo, Okla.—City is having plans arranged for the construction of a new municipal electric light plant. Bonds to the amount of $20,000 were recently voted to cover the cost of the work.

Hobart, Okla.—The electric light bonds have been accepted and sold and work will commence at once on the new system.

Hydro, Okla.—A bond issue for the purchase by the city of the electric light plant and ice plant carried.

Tahlequah, Okla.—A bond issue of $200,000 has been authorized by the city officials, to provide for the construction of a new municipal electric power plant.

Beeville, Tex.—Improvements in the electric light plant are contemplated.

Breckenridge, Tex.—Texas Power & Light Co. will install new equipment.

Dallas, Tex.—It is stated by Fred A. Jones, engineer who is in charge of the surveys now being made for the proposed interurban electric railway that is to be constructed between Dallas and Wichita Falls that eight tentative routes have been gone over and that the preliminary survey of the ninth route is now being made. It will be left to the executive committee of the Dallas-Wichita Falls Interurban Co., as to which route will be selected. The distance by the shortest route is 130 miles. Glen Stiff, right of way agent of the construction company, is working in conjunction with the field engineers.

Fort Worth, Tex. — Investigations are being made to get information on different systems of street lighting previous to the improvement of the city system here.

Fort Worth, Tex.—Construction of the proposed interurban line to Mineral Wells will begin Oct. 1. H. E. Robinson, promoter of the company, that proposes to construct the line with the Palo Pinto county watering place and afford the isolated section of Parker and Palo Pinto an outlet to market their produce and crops. The line will extend 60 miles west of Fort Worth with prospects of it being constructed to the oil fields of Stephens county via Breckenridge and on to Ranger and Cisco. When incorporated it will be known as the Fort Worth & Western Electric Railway Co., and will be capitalized at $3,000,000. The company is headed by H. E. Robinson.

Luling, Tex.—A petition is being circulated asking that the Board of Commissioners order an election on city bonds in the sum of $75,000 for installing a municipal lighting plant and water plant.

Ranger, Tex. — Construction of a system of interurban electric railways through the Central West Texas oil fields is planned by the Ranger Light & Power Co., which has just been granted a franchise for a street railway system here by the city commission. The first of the interurban lines to be built will run between Ranger and Eastland, 12 miles. The company will construct a large central electric power station here.

WESTERN STATES.

Boise, Ida.—Mackay Light & Power Co. was given permission by public utilities commission to extend its lines down the Lost river to Arco. In this event it is probable that the town of Arco will not proceed with plans for a municipally owned power transmission line 46 miles long for which a bond issue of $60,000 had been planned.

Marshfield, Ore. — An estimate of what it will cost to put the power plant at the Smith Mill in good running order in relation to both the part which supplies the power for the Mountain States Power Co., and that which furnishes power for the Smith Mill, has been completed by the consulting engineer of the power company. The cost is estimated at $60,000.

Roseburg, Ore.—William Polman, owner of the local light and water plant who resides at Baker, Ore., was here recently inspecting the property with a view to making improvements. Pumping and power plant on the North Umpqua will be improved and entire system put in shape.

St. Johns, Ore.—Construction of electric railway connections between the municipal terminal at St. Johns and the city street car system may be undertaken by the public dock commission, as the result of an offer from the Portland Railway Light & Power Co. The cost of the connection is estimated at $25,000.

Bellingham, Wash.—E. F. Williams, engineer of Seattle, will investigate the feasibility of a plan to divert the South Fork of the Nooksack river into the Skagit river with the idea of installing a power plant of about 14,000-kw. capacity. He is the owner of the water rights on the South Fork.

Kelso, Wash.—Contract for the substation at this place was awarded by the North Coast Power Co. to N. A. Strand, construction to start at once. The company also has a crew of men rebuilding the line from Kelso to Kalama to carry a load of 66,000 volts and a total outlay of $40,000 is being made by the company in this vicinity this summer.

Seattle, Wash.—Installation of an additional unit of 10,000-kw. capacity at the Lake Union Station plant will cost more than $75,000 according to estimates filed with the city council by J. D. Ross, superintendent of the city lighting plant who is urging immediate steps to meet what he says is a serious shortage of electrical power.

Seattle, Wash.—In connection with the proposed construction of the 18,000,000-ton capacity dry-dock at the plant of the Ames Shipbuilding & Drydock Co., large quantities of electrical equipment will be required, including complete electrically operated pumping apparatus, motors, etc.

Wenatchee, Wash.—Plans are being perfected by the Okanogan Valley Power Co. for the construction of a new dam and power plant on the Similkameen river, in the vicinity of its present works. It is understood that the proposed plant will have a capacity of 5000 hp.

Petersburg, Alaska — Citizens are organizing a company to install a hydroelectric power plant on Five Mile creek, to deliver power to the city. The City Council is to constitute the majority of the board of directors and the company is to issue bonds for $40,000, the estimated cost of the first unit of the plant, the bonds to be taken up by the city, which will become the owner of the enterprise. H. P. Crowther of Juneau is doing the engineering work.

Fresno, Cal.—Announcement has recently been made by the Pacific Telephone & Telegraph Co. that plans are now in process of formation for extensions in its cable system in the north and east sections of Fresno to be inaugurated during the coming fall. The work is estimated to cost about $55,000. Maynard Bailey is superintendent of the Fresno district.

Greenville, Cal. — Trask Copper Mining Co. has recently completed the construction of a new power line from Englemine to its local mining properties. Power for operation will be supplied by the Great Western Power Co.

Holtville, Cal.—Holton Power Co. is arranging final plans for the installation of new electric generating equipment in its dismantled power plant at Holtville. It is understood that the work is estimated to cost about $75,000. E. A. Judy is district manager.

Los Angeles, Cal.—Plans are being arranged by the Southern California Edison Co. for the installation of new generating equipment in its Big Creek plant No. 2, located about 240 miles from Los Angeles in Fresno County. In this connection the company will be obliged to construct an additional pipe line. It is understood that plans are under consideration for the installation of a similar unit in power plant No. 1 at a later date.

Los Angeles, Cal.—Large quantities of electrical equipment will be required in connection with the construction of municipal power plant No. 2, located in the San Francisquito Canyon, the entire installation being estimated to cost about $500,000. The machinery will include electric generating equipment, transformers, hydraulic equipment, and auxiliary electrical apparatus.

Los Angeles, Cal.—In connection with the proposed plant of the Keystone Iron Works, Merchants National Bank building, estimated to cost in excess of $100,000, large quantities of electrical equipment will be required, including three electrically operated cranes, motors, etc. The new works will be located on Santa Fe avenue.

Los Angeles, Cal.—Public Service Commission has approved plans for the installation of the proposed new ornamental lighting system on Broadway, to extend from California street to 10th street. The entire work is estimated to cost approximately $100,000.

San Diego, Cal.—The City Council is understood to have authorized the preparation of estimates of cost for the construction of a new municipal electric light and power plant, now under consideration. W. H. Judy is city manager of operation.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number given.]

Electrical Goods (29,921).—An electrical dealer in France desires to represent manufacturers of electrical goods in Brittany, except conduit, but particularly electric fans. Correspondence should be in French.

Electrical Equipment (29,931).—A merchant from France who is in this country desires to purchase from manufacturers only, for Roumania, iron and steel, and products, electrical goods, automobiles, rubber goods, agricultural machinery, machinery, hardware, electric railway cars and equipment for electric railways, glass and general merchandise. References.

Electrical Supplies (29,934).—A firm in this country is about to send a representative to Cuba to establish branch offices and desires to secure exclusive agencies from manufacturers of all kinds of hardware, tools, nails, roofing materials, railroad accessories of all kinds for tracks used on sugar plantations, dry goods, paper, special wrapping paper, electrical supplies, drugs and chemicals, and any merchandise that will find a ready sale in that country. References.

Vacuum Cleaners (29,933).—A firm in Belgium desires to purchase or to secure the agency for the sale of sanitary ware, heaters for bath, radiators, valves and accessories, and vacuum cleaners. Quotations should be given c. i. f. Antwerp. Payment, cash against bill of lading at Antwerp. Correspondence should be in French. References.

Electrical Goods (29,911).—A company in the United States composed of Americans and native Finlanders, who are going to send representatives to Finland, desire to purchase and secure the agency for the sale of all kinds of foodstuffs, wearing apparel, machinery, agricultural implements, electrical goods, etc. Reference.

Electrical Materials—Furnaces (29,945). — A mechanical engineer, graduate of an American university, will be in America to secure commission or consignment contracts for sale in Belgium of electrical material and supplies, metallurgical appliances, rolling mills, electric furnaces, ores, coal, etc.

Electrical Supplies (29,876).—The purchase by a company in Norway of electrical industry supplies, gas and electric fixtures, iron, steel boilers, various metals, shipbuilding materials, engines, electrical cable-making machinery, flour-mill machinery, motion-picture machinery, raw rubber, porcelain insulators and porcelain articles used in electrical industries, is desired. Terms, cash against documents. Reference.

PROPOSALS

Street Lighting System.—Bids will be received by J. W. Allard, city clerk, Osawatomie, Kans., until 8 p. m., July 28, for furnishing all material and installing a special street lighting system to consist of 102 metal lamp standard, steel topped and lead covered cable, street light switchboard panel, crossarms, pole-line hardware, No. 8 triple-braid waterproof wire and all appurtenances called for in plans and specifications, which may be secured at the office of the city clerk or the engineers, Black & Veatch, Interstate building, Kansas City, Mo. Contractors desiring plans will be required to deposit $10, $8 of which will be refunded when the plans are returned. Certified check $500.

INCORPORATIONS

Los Angeles, Cal.—Guaranteed Battery Equipment Co. has been incorporated with a capital of $25,000 to manufacture batteries, equipment, etc. T. S. Juden, H. M. Motzkus, T. O. Osborn, C. E. Corson, and Edward Corson, all of Los Angeles, are the incorporators.

Philadelphia, Pa. — Electro-Lyte Storage Battery Co. Incorporated under Delaware laws with a capital of $200,000 to manufacture storage batteries, etc. Incorporators: R. F. Hansell, Philadelphia; E. M. MacFarland, and J. Vernon Pimm, Camden, N. J.

Personal

E. C. Bennett Joins International Paint Corp.—Ervin Dryer Opens Sales Engineering Office—I. B. Zimman Promoted

HERMAN G. HARDY has assumed the position of chief mechanical and electrical engineer of the Arizona Copper Co., Ltd., Clifton, Ariz. He was formerly associated with the Old Hickory Powder Plant, Jacksonville, Tenn.

ROY PAGE, for the past two years associated with the Nebraska Power Co., has been appointed to the position of general superintendent, having direct supervision of the power station, purchasing department, garage, storeroom and the claims and welfare department. Prior to joining the Nebraska company Mr. Page was for some time connected with the Southern Pacific Railroad.

C. D. MCCLARY, who has been with the Western Electric Co. since February, 1910, has been made sales manager of the Pittsburgh office, effective July 1, 1919. Mr. McClary was first connected with the Philadelphia office and transferred to Pittsburgh in the latter part of 1910. In April, 1916, he joined the sales force, and in April, 1918, was promoted to the position of assistant sales manager, continuing in that capacity until his recent promotion.

I. B. ZIMMAN, manager of the sales and service department of the Nebraska Power Co., Omaha, Neb., has been promoted to the position of assistant general manager in charge of public relations. He will have supervision of the company's general relations with the public, franchises, municipal contracts, taxes and property assessments, reporting to the vice-president and general manager. Mr. Zimman has been connected with the Nebraska Power Co. and its predecessor, the Omaha Electric Light & Power Co., in various capacities for 17 years, principally in new-business work.

ERVIN DRYER has opened an office as sales engineer at 1535 Old Colony building, Chicago, and will handle steam, electric and hydraulic lines with an organization for doing the necessary engineering work in connection with the installation of such equipment. Mr. Dryer is one of the best known engineers in the Middle West, having had much to do with the design and construction of many of the most prominent power stations in this territory. He was graduated from the University of Illinois in the mechanical engineering class of 1887. He first became connected with the United States Electric Lighting Co., and when this company was taken over by the Westinghouse Electric & Manufacturing Co. he was made sales engineer in the Chicago territory. In 1904 he left the Westinghouse company to become a sales engineer in the Chicago district for the Allis-Chalmers Manufacturing Co., which position he had held continuously until the present time. Mr. Dryer is affiliated with a number of technical and engineering societies and has taken a very prominent part in the development of steam-electrical engineering.

ELL C. BENNETT, of St. Louis, has resigned from the office of seventeenth Mercury of the Jovian Order, to which position he was elected last October to serve until January, 1920, to join the International Paint Corp. in the capacity of secretary and general manager. This company, under the name of the Railway Supply Co., has been engaged in the production of paint

Ell C. Bennett.

oils, graphite and asphaltum paints for a number of years. Its capital stock has been increased to $150,000. The plant is located in East St. Louis, Illinois, with headquarters in St. Louis, and it will specialize in paints used in the electrical industry. Mr. Bennett served the Jovian Order for a longer period than any other elective officer in the history of that body, being elected for eight consecutive years. During his term of office the Order grew from less than 5000 members to nearly 20,000, the peak being reached just prior to the outbreak of the world war. Since that time the stress of war and changing conditions in the electrical industry have operated to materially reduce Jovian numbers.

L. W. W. MORROW, who has been at Yale University on leave of absence from the University of Oklahoma during the past year, is retained at Yale as assistant professor of electrical engineering. Professor Morrow was in charge of one of the divisions of the Signal Corps Training School for officer candidates while it was active. When at the University of Oklahoma Professor Morrow was director of the School of Engineering and took an active interest in public utilities of the state, particularly in connection with engineering and valuation matters.

Obituary.

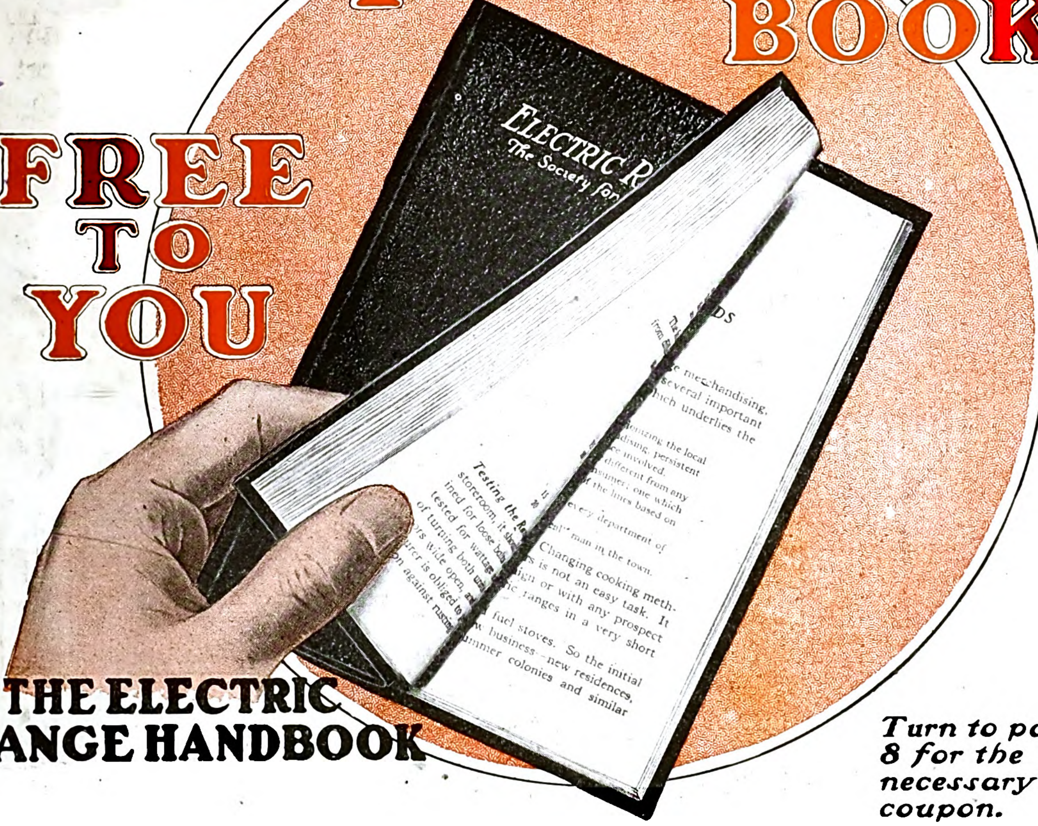
GEORGE B. WEBB, capitalist and organizer of street railways and telephone companies, died July 7 at Baltimore at the age of 60. Mr. Webb began his business career with the Baltimore & Ohio railroad and subsequently in connection with Harry Parr he constructed the Baltimore & Northern railroad. Then with Alexander Brown & Sons, bankers, he consolidated the street railways of Baltimore, and for a short time was the president of the amalgamated companies. Mr. Webb's activities rapidly broadened. He organized the Maryland Telephone Co., the Pittsburgh & Alleghany Telephone Co., Wilmington Light & Power Co. and the Duquesne Light Co. of Pittsburgh. At a later period, with Baltimore associates, he consolidated the United Railways of San Francisco, and with Pierre S. du Pont and Harry P. Scott he consolidated the street railways and light and telephone system of Wilmington, under the name of the Wilmington & Philadelphia Traction Co.

BARON RAYLEIGH (John William Strutt), known as "Peter Shopkeeper" and as one of England's greatest physicists, died on June 30. He was born in 1842, a descendant of Sir Godfried Strutz de Winkered, who resided in Essex as early as 1240, and was graduated as senior wrangler at Trinity College, Cambridge, in 1865. From 1879 to 1884 he was Cavendish Professor of Experimental Physics in Cambridge University, and in 1887 he accepted the post of Professor of Natural Philosophy at the Royal Institution of Great Britain. He was awarded the Noble Prize for physics in 1904. Baron Rayleigh became well known throughout Europe many years ago by his papers on mathematics and physics, written under the name of "J. W. Strutt." The scope of the subjects treated in his essays was large and included such specialized subjects as chemical physics, theory of gases, flow of liquids, photography, optics, color vision, wave theory, and problems in the theory of electricity and magnetism. A characteristic of his experimental apparatus, which was designed and built by himself, was that it was unusually crude and unpretentious in appearance, but that it was essentially perfect and demonstrated his theory accurately. At the time of his election as Chancellor of Cambridge University in 1908, his reputation was such that it was said of him that "since the death of Lord Kelvin he is the most eminent chemist in Christendom."

Electrical Review

Vol. 75. No. 4. CHICAGO, JULY 26, 1919 Three Dollars a Year

THIS $1.50 RANGE BOOK FREE TO YOU



THE ELECTRIC RANGE HANDBOOK

Turn to page 8 for the necessary coupon.

HERE is a book that tells you what you want to know about Electric Ranges. It is prepared and published by the Society for Electrical Development, Inc., and consists of 208 pages of good solid facts based on the experiences of Central Stations all over the country who have been putting Ranges onto their lines. There is nothing theoretical about the book. You learn by the experience of others.

Turn to page 8 of this Review. Fill out the coupon you will find there and mail it to us at once. Although the book is usually sold by the Society for $1.50 the Hughes Division has secured a limited number of copies for Central Station men contemplating Range campaigns. The coupon mailed us at once will bring you your copy before it is too late.

Electrical Review

WITH WHICH IS CONSOLIDATED WESTERN ELECTRICIAN AND ELECTROCRAFT.

VOL. 75—No. 4. CHICAGO, SATURDAY, JULY 26, 1919. PAGE 135.

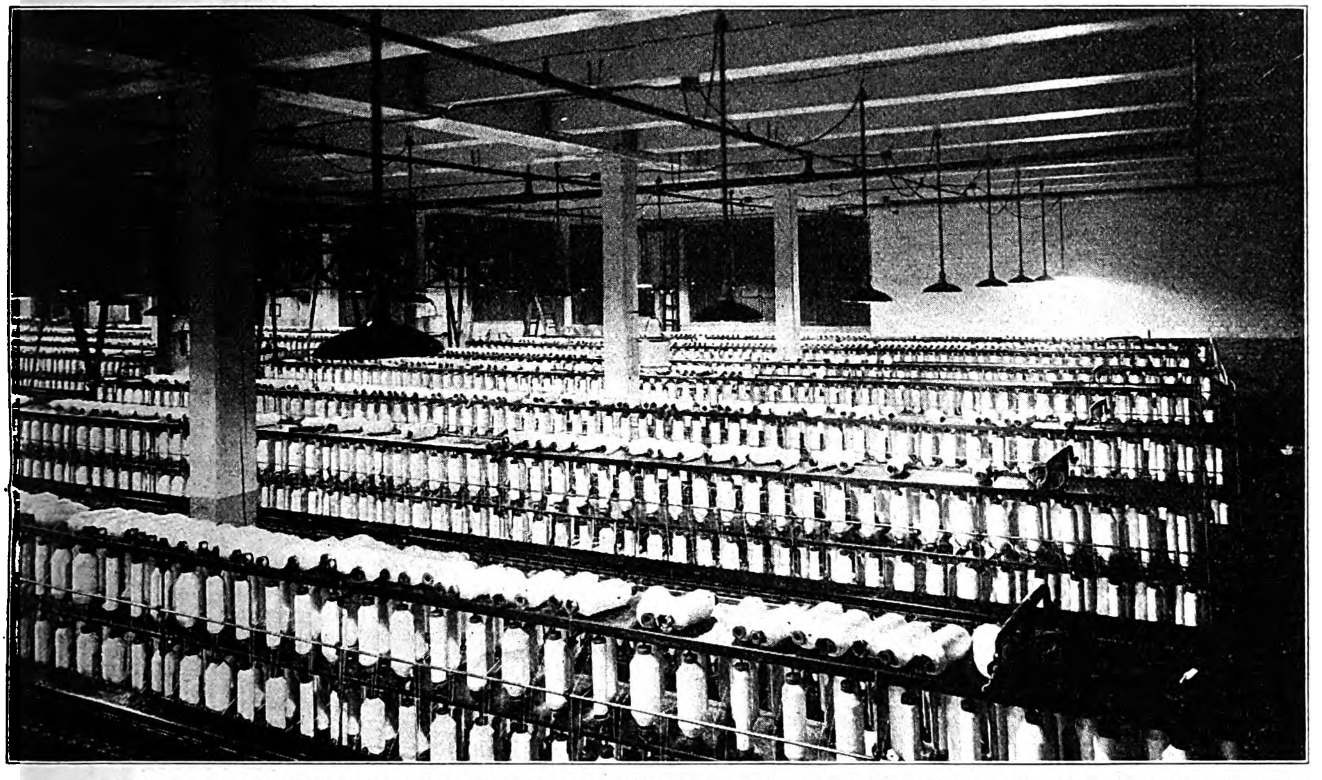

Fig. 1.—Night View in a Spinning Room, Showing General Illumination Meeting All Requirements—Fixtures Can Be Easily Taken Down for Cleaning or Repairs, an Important Feature in a Cotton Mill.

Canadian Textile Mill Operated by Central-Station Service

Canadian Cotton Co.'s Plant Electrically Equipped Throughout — Remote Control and Other Features of Motor Service — Exceptionally Good General Illumination in Every Department

By V. K. STALFORD

Hamilton District Inspector, Electrical Inspection Department, Hydro-Electric Power Commission of Ontario.

A VERY fine example is shown in the accompanying illustrations of a textile mill operated entirely from central-station service. It is the new plant of the Canadian Cotton Co., and is located in Hamilton, Ontario, Canada.

This mill manufactures all grades of cloth used for making overalls, mattresses, bed ticking, and light ducking. The building occupies an entire city block, about 300 ft. square and faces three streets. It is of mill type construction, three stories high. The total load is approximately 1000 kw., including lighting and power. This is an ideal load for central-station service. A number of the manufacturers in this territory had very great difficulty during the war in obtaining coal supplies and they are now contemplating central-station service to prevent recurrence of these difficulties.

The latest practice in the textile industry is to have all motors controlled entirely from a centrally located power house or substation, maintaining an operator at this substation at all times. The motors are only equipped with the emergency switches to permit disconnecting the same in case of accidents or other emergency. In this mill Detroit "Square D" enclosed switches are used near the motors for this purpose.

In Fig. 2 a view in this substation is given, showing two rows of panels with starting switches for each motor and the necessary meters. A 150-hp. 220-volt, two-phase, 66⅔-cycle motor is shown in the center of the photograph for operating one of the weave rooms. The control for this motor is shown at the right of the picture. All the equipment in this substation was supplied by the Canadian Westinghouse Co., and installed by it. Each motor is started and stopped from this substation by the operator. Ammeters and voltmeters are used to give indications of the starting condition of each motor.

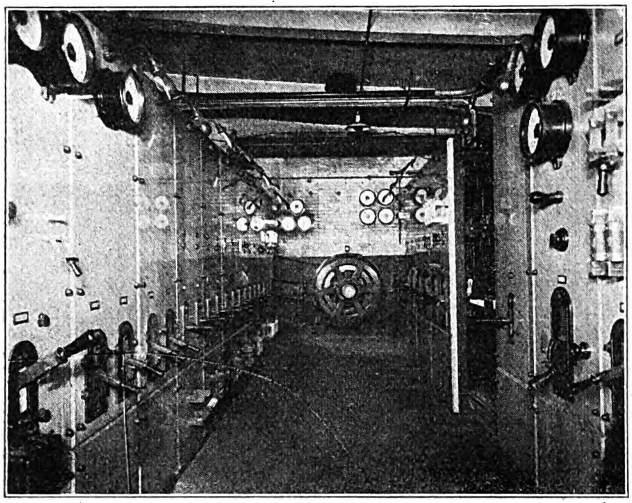

Fig. 2.—View in Central Substation, Showing Motor Control Panels and Distributing Boards—A 150-Hp. Motor Is Also Shown.

Fig. 3 is a rear view of the panels, showing the starting and running fuses. On the right-hand side of the illustration are shown the autotransformer coils with interlocking knife switches for rearranging the percentage taps of the autotransformers. This is a very compact installation. Sufficient space is provided at the rear of panels for making all necessary repairs.

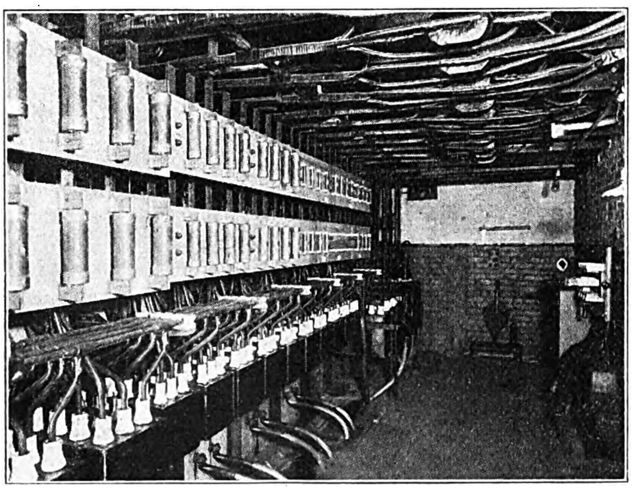

Fig. 3.—Rear View of Motor Control Panels in the Central Substation, from Which Nearly All the Motors Are Controlled.

Samples of the electric lighting throughout this mill are given in four of the accompanying illustrations. These are considered excellent examples of modern textile-mill lighting. The management of this mill recognized that it is most important to have proper lighting facilities in order to reduce accidents during the hours of darkness and semidarkness. The factory lighting shown in these views will increase production, decrease cost, improve quality, reduce spoilage, and prevent accidents. In other words, it will not only improve production, but also conserve the human material in the textile industry which is its most valuable asset. The average time of artificial lighting in factories of this type is three hours per day. It is most important that the working conditions under artificial lighting should equal closely those of the best daylight at all working hours. This is more particularly true where night shifts are working.

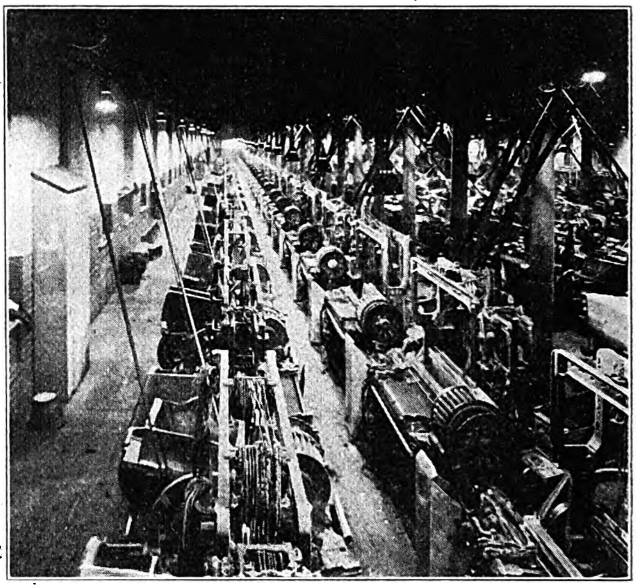

Fig. 4.—Night View in One of the Weave Rooms—Illumination That Has Been Found to Give Most Satisfactory Results.

Efficient lighting throughout the factory is equal to good tools. No foreman or superintendent would expect the workman to properly perform his task with poor tools. The workman and machinery are a combination and as such must work harmoniously. The machine may be the best type that can be obtained, but with poor lighting the workman is handicapped, consequently the combination cannot produce satisfactory work to the highest efficiency. As the practice

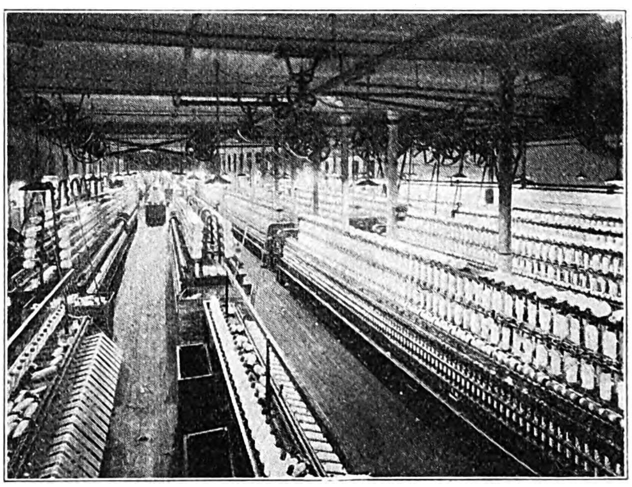

Fig. 5.—View in One of the Spinning Rooms—General Illumination That Floods the Whole Room in Light.

now is to reduce working hours it will be necessary to increase production accordingly. It is the prime purpose of every plant to earn as much profit as possible; in fact, this is the reason for its existence. Therefore, if the manufacturer neglects to install proper illumination, he is taking cash from his pocket to pay for his own carelessness.

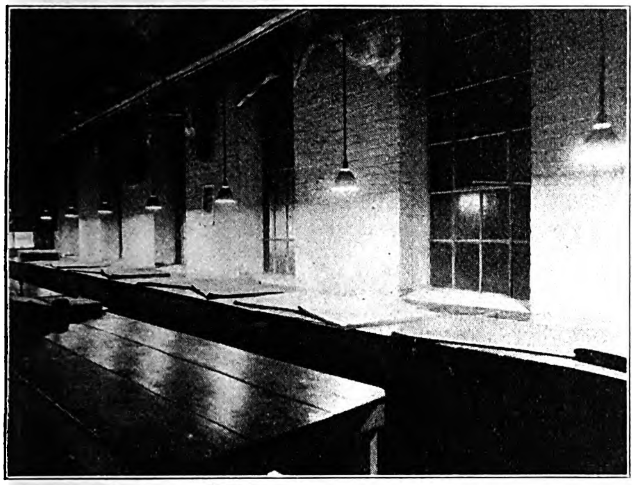

Fig. 6.—Inspectors' Tables Effectively Lighted to High Intensity so That Any Defect in the Cloth Can Be Detected Before Finishing and Shipping.

These ideas were given careful consideration before deciding on the lighting of this mill. In designing the installation thought was also given to the fundamental principles for lighting, which are: Correct intensity, good diffusion, lighting from the proper direction, absence of drop cords, and absence of glare, both direct and reflected.

Fig. 4 is a night view in one of the weaving rooms. The units in this room are 60-watt Mazda lamps in Benjamin deep bowl reflectors mounted approximately 7 ft. from the floor, located directly over the center of the machine. This has been found to give the most satisfactory results. The units at the rear of the machines are spaced approximately 15 ft. and 9 ft. from the floor. As these are only for general lighting purposes it is not necessary to have so great an amount of illumination at the rear of the machine.

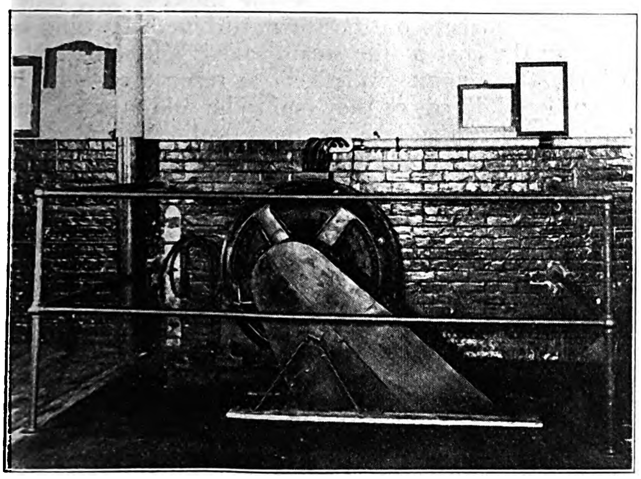

Fig. 7.—One of the Motors Connected to Drive a Group of Machines Through Silent-Chain Belt Drive.

In Fig. 5 is shown a view in one of the spinning rooms, using Benjamin shallow bowl reflectors of 60-watt size with 25-watt Mazda lamps and mounted 7 ft. from the floor.

In Fig. 1 another view is shown in the spinning rooms. The detail shown is very clear and there is a marked absence of confusing shadows. The fixture used throughout this mill is the Benjamin hanger with shock absorber suspended from the screw hook in the wooden ceiling. Reinforced cord is suspended between the outlet box and the fixture. Bryant type KA No. 13 receptacles are used in the outlet box for connecting the fixture plug; this provides a ready means for disconnecting the fixture so that it can be taken down for cleaning and repairs. This type of receptacle is very flexible for factory work.

Fig. 6 gives a view of the class of lighting used at the cloth inspection table where the final inspection is made of all of the cloth for defects before it is shipped to the customers. It is most important that this lighting should be as nearly perfect as possible in order that the inspector can find the defects. Benjamin 100-watt bowl reflectors with 60-watt Mazda C lamps are mounted approximately 3 ft. above the bench and on 6 ft. centers.

This lighting system has been in use for over one year, and the management is entirely satisfied with the excellent results obtained therefrom.

Fig. 7 is a typical installation of one of the motors with Link-Belt silent-chain drive enclosed and operating in oil. Group drive has been extensively used throughout the mill, using motors of 50 hp. and larger.

NEW POWER PLANT FOR PITTSBURGH DISTRICT.

Duquesne Light Co. to Erect Big Power House at Cheswick, Pa., to Serve Entire Pittsburgh District.

The Duquesne Light Co., Pittsburgh's central-station organization, has made arrangements for floating a $25,000,000 30-year bond issue, the bulk of the proceeds of which will be used for building a big new power plant at Cheswick, Pa., of such capacity that it can supply all of the electric power needs of the Pittsburgh district for an indefinitely long time in the future.

This plant will be along the Allegheny River within two miles of a 3000-acre thick-vein Freeport coal tract of the Equitable Coke Co., a subsidiary of the Philadelphia Co., which controls the Duquesne Light Co., thus assuring abundant supplies of water and fuel.

During the war a comprehensive survey was made by engineers of the War Department of Pittsburgh's probable power needs and it was estimated that the probable maximum demand was equal to 556,000 kw. The power plants of the Duquesne Light Co. have now a capacity of more than 156,000 kw.

Transmission lines will be erected to reach every vital part of the Pittsburgh district and to connect the various power plants and substations in such a way that uninterrupted electric service will be assured at all times. The Duquesne Light Co. now has 85,000 customers, 7 generating stations, 163 substations, 7375 miles of electric conductor and almost 1000 duct miles of underground conduit.

FAN SALES BREAKING RECORDS.

Reports from many parts of the country indicate that the present will probably be the best electric fan season in numerous cities. The continued hot weather has exhausted stocks at several points. In fact, the early onset of the hot spell in June caused unusually heavy sales for that month which are continuing. The records of 1916 are likely to be broken.

Central-Station Rates in Theory and Practice

Third Article—Capital Charges of Central Stations and How they Affect the Demand Cost—Interest and Depreciation—Influence of Peak Load on Expense

By H. E. EISENMENGER

This is the third article of a series to appear weekly throughout the current volume. A general outline of the entire series was published in the issue of July 5 and the first of the articles appeared July 12. In the first two articles the author discussed costs in general and then took up the cost of electric service in particular, showing that the three principal elements of this cost are energy cost, demand cost and consumer cost. The present article continues the discussion of demand cost, which will necessarily be extended through several installments. The reader must realize that a knowledge of the various elements on which the cost of the service depends is necessary before the subject of rates (or price of the service) can be properly discussed.

PART I—THE COST OF ELECTRIC SERVICE—Continued.

II-A. THE THREE ELEMENTS OF COST.

A. THE TOTAL DEMAND COST OF THE PLANT.

2. *The Constituents of the Demand Cost.*

a. Capital Charges.

1. Net Return (Interest, Dividend).

SECTION **18.** The capital invested in a commercial enterprise has been paid in by its owners because they have the belief that they will get a satisfactory return, whether that be a certain prearranged fixed percentage, as on bonds, or a variable one in accordance with the degree of success of the business. (See Insert III-A.)

This return on the capital is the *raison d'être* of any business enterprise and therefore it has been mentioned first. As a matter of fact it is the last one of the capital charges inasmuch as all the other charges to be mentioned hereinafter (depreciation, repayment, taxes, insurance, etc.) must be, or should be, considered first. We can thus distinguish a gross return and a net return, both of them being based on the *net* income. The gross return includes all capital charges, or at least depreciation and possibly repayment[1]; after deducting all those charges from the gross return we get the net return which is paid to the owners of the capital as bond interest and stock dividend.

We have therefore to distinguish the following four items:

1. Gross income.
2. Net income = gross income — cost.
3. Gross return $= \dfrac{\text{net income}}{\text{capital}}$, usually given in per cent.
4. Net return = percentage gross return — percentage depreciation, etc.

2. Depreciation.

19. For practically all construction work, whether it be machinery, or buildings, or electric lines, etc., we can figure that after a certain number of years it has to be replaced because it is worn out and useless. How great this number of years is depends largely on the nature of the construction. A building may last 50 years or longer, a pole of an overhead line may be too decayed for further use after 10 years or less, etc. The value will decrease year after year and this is called the depreciation of the construction.

Moreover, some parts of construction, especially machinery, must not infrequently be discarded long before they are physically unfit for further use because new inventions have been made and it has become either more economical or otherwise advisable to install machinery which embodies the new improvements rather than to continue employing the old obsolete machinery. This has, for instance, been frequently done in the last few years with reciprocating steam engines, which, although still in their prime of life and perfectly serviceable, had to be exchanged for the newly invented steam turbine because the latter consumes so much less steam (and requires so much less space) that the whole interest and other investment charges on the steam-turbine set would be less than the cost of the steam saved[2] annually. The reciprocating engines were kept as reserve capacity in case of breakdowns or they had to be sold at what one could get for them—that is, the so-called scrap value, which generally is only a small percentage of the price paid originally.

We see therefore that the value of the capital invested in an electric plant is not, without further measures, safe and secure for all times, but that on the contrary this value is incessantly and automatically being reduced and we must take steps to counterbalance this reduction of value by creating a fund into which the equivalent of the depreciation is deposited out of the annual earnings before we apply the latter for profit.

Suppose, for instance, we have bought a generator set for $100,000 and after 12 years it is worn out and has to be scrapped, the scrap value to be $10,000. The balance of $90,000 has disappeared out of the generator set and if we do not want to lose that amount we must have earned so much over and above the

[1] Taxes and insurance are frequently counted as cost, although from the present point of view they should rather be classified as capital charges.

[2] And capital charges on the floor space saved, which can be utilized for extensions of the capacity.

interest that the aggregate of these yearly excess earnings with compound interest has accrued after 12 years to make up the $90,000 which has disappeared. We have to establish a "depreciation fund" into which regular payments are made every year and invested at compound interest. That means, for instance, if we invest the money accumulating in the fund at 5% compound interest, we have to pay in every year about $5650 for depreciation, or 5.6% of the original capital of $100,000; then at the end of 12 years we will have $90,000 accumulated in the fund which, together with the expected proceeds of $10,000 from the sale of the scrapped generator set, will just about suffice to buy a new generator set in place of the old one.

Of course, all these calculations have to be rather crude ones as the figures we are dealing with are all known only very approximately. We do not know what the actual useful life of the generator will be. We can be guided from past experience, which is laid down in tables for various classes of machinery and other constructions, but these tables give, of course, only average values and, moreover, when it comes to obsolescence, due to future new inventions, we are entirely at sea. Even apart from obsolescence, we do not know how great the scrap value will be and what the price of the new generator set will be in about 12 years from now, etc. But something near that figure (5 or 6%) will have to be put aside every year for depreciation in the assumed simple case.

20. It is obvious that in this hypothetical simple example the money in the depreciation fund rises from zero at the beginning of the first year to 100% of the net replacement value at the end of the twelfth year and then drops suddenly to zero again as the new generator is bought. This 12-year cycle is periodically repeated an indefinite number of times. As the value disappears from the physical property by depreciation it turns up in the depreciation fund and then by purchase of a new equipment flows back into the physical property, thus fluctuating in a 12-year cycle to and fro between the two. In practice, however, the fluctuations of the fund are not as large but much smaller, for several reasons, which are briefly explained in Insert III-B.

3. Repayment (Sinking Fund).

21. Where, as usually, a portion of the company's capital has been raised by bonds, these bonds mature within a certain time, for instance, after 20 or 30 years; this means that the principal (face value of the bonds) has to be paid back at that time according to the terms of the loan. It is then most commonly raised by a new issue of bonds. An alternative is the creation of a fund for the payment of the bond indebtedness ("sinking fund"). A certain amount must be paid into this fund every year of such size that at the time when the bond issue matures the accumulations in the fund with compound interest aggregate to just the face value of the maturing bond issue.

In some cases the franchise granted to the company stipulates that the franchise will expire after several decades, perhaps after 30 or 50 years, and that the equipment of the company has to pass at that time into the hands of the city, or some such body, without any compensation whatever to the company. If we want to be very exact and careful, we will have to create another sinking fund in such cases of such size that this fund, together with the liquid amount contained in the depreciation fund at the end of those 30 or 50 years (or whatever the term is), amounts to just the capital invested. The depreciation fund and the sinking fund together will then, at the time of the termination of the franchise, serve to pay back the face value of all stocks and bonds. Now, it is obvious that under these conditions any company will endeavor to avoid replacements of machinery, etc., during the last years of its franchise, as it knows that in the near future it will have to give up, without any compensation, its physical property. Consequently, at the end of the period the depreciation fund will be as nearly 100% filled as it can be. The plant will be run down and an unusually large portion of its value will have passed over into the depreciation fund. For this reason and because, in view of the great length of time, the annual payments into a repayment fund of that kind would be a very small percentage, these payments are sometimes neglected.

4. Other Capital Charges.

22. Interest, depreciation and possibly repayment are not the only annual capital or investment charges. *Taxes* are mostly in accordance with the value of the property—that is, in first approximation, with the capital invested. The cost of *insurance* also is the higher, the costlier the plant. These two items may therefore in first approximation be regarded as proportional to the capital invested.

23. We come to the conclusion that we can, as an approximation, assume every one of the capital charges, whether interest, depreciation, repayment or other charges, as proportional to the capital invested and therefore we can also assume the sum of these items, that is, the total capital charges, to be approximately proportional to the capital invested. The capital charges are therefore proportional to the plant capacity and in further approximation to the plant's peak load.

b. Demand Cost Other Than Capital Charges.

24. In addition to the above expenses we have certain other expenses which are not capital charges but which also depend on the size of the plant only, and may be assumed to be proportional to the latter and consequently to the peak load.

Thus, a certain portion of the fuel and lubricating cost and of the cost of maintenance and repairs, etc., may depend on the size of the plant. To explain this, let us assume, for instance, that we have to generate 24,000 kw-hr. in 24 hours by a 1000-kw. generator set, running at full load. Let us assume further that we have in another instance to generate the same number of 24,000 kw-hr. in the same total time of 24 hours, but no longer at uniform load, but with a 4-hour uniform peak period of 5000 kw. This would, of course, require an equipment of larger capacity, for instance, a 5000-kw. set instead of the 1000-kw. set. During these four peak hours the generator would furnish $4 \times 5000 = 20{,}000$ kw-hr., leaving 4000 to be generated during the remainder of the day—that is, during 20 hours. The average load during these 20 hours will therefore be only 200 kw.—that is, 4% of the capacity of the 5000-kw. generator.

Now, large generating units are more efficient than small ones; that means they are consuming fuel more economically per kilowatt-hour output than small ones running at the same percentage of their normal (full) load. The same refers to consumption of lubricants. On the other hand, there is a certain economic load for every generator set at which the latter is most efficient; this load is near the rated or normal load of the set. As the load decreases below that amount the specific fuel and oil consumption *per kilowatt-hour* is getting larger and larger, and for small percentages of full load it will become quite high.

In the assumed example the 5000-kw. generator will therefore work more efficiently than the small one during the four hours of its full load, generating in that time 20,000 kw-hr. During the remaining 20-hour period the large generator will work less efficiently than during the peak load period and, in fact, it will work quite wastefully, as it is running at only 4% of its normal load. The average efficiency at which the large generator supplies the energy is therefore in general different from the efficiency of the 1000-kw. set. It may be higher or lower, depending on the way in which the efficiency varies with the size of the generator and with the percentage of the load. In practice, these figures are such that an increase of the demand will under the given conditions probably always result in a decrease of the average 24-hour efficiency and therefore in an increase of the fuel and oil consumption.[3] We see from this how the peak load of the central station influences the cost of fuel and lubricants in such a manner that under the given assumptions a part of these costs may be assumed to be proportional to the peak load.

Similar considerations prevail for the maintenance and the repairs of the equipment. As regards the total cost of attendance, it will of course always be larger for a larger machine than for a smaller one, etc.

25. We see in this manner that there are certain costs which are not investment charges, but still are dependent on the peak load and can be assumed to be proportional to the peak load. Together with the capital charges which are, as shown, also approximately proportional to the peak load they make up the *"demand cost,"* sometimes called *"fixed cost."* The demand cost of a central-station plant can therefore be assumed as being proportional to the central station's peak load. This involves, as we have seen, certain approximating assumptions which are recapitulated and discussed more in detail in Insert V.

Insert III—Appendix to Sections 18 and 20.

Interest and Depreciation.

A. Interest on the Capital Invested.

(To Section 18.)

The capital invested in fairly sized electric central stations is practically never the property of an individual, but belongs almost always to a corporation and we have to distinguish various ways in which this capital or its parts have been raised, as this influences the distribution of the interest.

A (physical or juristic) person desiring to invest money in an enterprise of that kind may do so either by becoming part owner of the company's property or by lending money to the owners at a certain prearranged rate of interest without acquiring any rights or duties of ownership in the latter case. The company's property serves as security for the loan. In the first case the person investing money receives *shares of stock*, which are certificates that he shares in the ownership, and in the second case he receives *bonds* (or notes), which are receipts for money and a promise to pay together with interest at a rate agreed upon. When a person buys stock he becomes in a sense a partner of the enterprise and if he buys bonds or notes he becomes a creditor and as a creditor has no proprietary interest.

The capital may be raised entirely by bonds (municipal enterprises), or entirely by stocks, or (usually) partly by stock and partly by bonds. The revenue of the enterprise is used to defray the running expenses (wages, salaries, raw material, etc.), after this the fixed amount of interest on bonds and the other capital charges, like depreciation funds, sinking funds, etc., (see Sections 19-22) are taken care of. The stockholders are entitled to the entire balance, which may be large or small or zero, according to the prosperity of the enterprise.

The stock may be all *common stock* or a part of the capital may have been raised by the issuance of *preferred stock*. The difference between common stock and preferred stock is the same as that between stocks and bonds, as far as the payment of interest is concerned. The holders of the preferred stock receive a certain prearranged rate of interest from the balance of the earnings after the bond interest has been deducted and, unless the preferred stockholders can receive their full rate of interest, the holders of the common stock will not be paid any return on their investment. Sometimes the preferred stock is subdivided into first and second preferred, so that the interest on the second preferred is paid out of the balance remaining after the deduction of the interest on the first preferred.

The preferred stock may be "participating" or "non-participating." In the first case, after the preferred stock has received the dividend provided for, and after the common stock has received a certain prescribed dividend, the balance of the profit is divided between the preferred and the common stock. In the second case, which is the usual one, the whole balance goes to the common stock.

The dividend on the preferred may be "cumulative" or "non-cumulative." This means if the enterprise has not had earnings enough to pay the full percentage on the preferred stock in one year the holders of cumulative preferred stock will be indemnified at the expense of the common-stock dividend as soon as the earnings become better in subsequent years, whereas with non-cumulative preferred the holders have no claim for indemnification out of the earnings of later years.

B. A Few General Remarks About Depreciation Funds.

(To Section 20.)

The reasons why the depreciation fund does not, as may seem from the simple example of Sections 19 and 20 of the main text, fluctuate between 0% and 100% of the net replacement cost but within much narrower limits are briefly the following:

In the first place, the plant contains different parts with different lengths of life so that the fluctuations of the respective parts of the depreciation fund overlap each other.

In the second place, the growth of the plant in the course of the years must be considered; in other words, the fact must not be lost sight of that the entire existing plant has not been built at the same time, but at different periods. This causes another overlapping and consequent smoothing out of the fluctuations of the various parts of the depreciation fund.[1]

In the third place, where we have a greater number of parts of the plant, even if all have the same average life and all have been installed at the same time, they will not all have to be replaced in the same year, because the actual life of the individual part is generally not equal to the average life. If, for instance, we have installed in a certain year a new transmission line with wooden poles having an average life of 10 years, though we will have to replace a large number at the end of the 10th year and in the years near it (for instance, between the ends of the 6th and 14th years), yet when the transmission line is old enough so that every pole has been exchanged several times, the varying periods of life of the individual poles evidently will overlap finally to such a degree that we have to exchange the same number of poles every year, namely, 10% of the total number.

That the depreciation fund is far from reaching 100%, even at the time when the first replacement is due, is shown by Table 1, which is based on the arbitrary but verisimilar assumption that the number of poles which require their first replacement in each year is as given by Column II of the table. (The interest accruements to the fund and the consequent reduction of the annual payments are disregarded in this table as non-essential for the present purpose.)

---

[3] We would, of course, for the very reason of improving the economy of generation not install (as assumed) one unit of 5000-kw. in the above example, if we could choose the size and the number of the generating units in such a manner that a better 24-hour efficiency can be obtained. It is then conceivable that the change of the load curve (that is, the increase of the peak load) may bring about a reduction of the fuel and oil cost, that is, that the percentage of the fuel and lubricant expenses (which is proportional to the peak load) is negative. The explanation of this apparent contradiction with what has been found above is given in Insert IV—"The Influence of the Central Station's Capacity (Peak Load) on the Operating Expenses."

[1] Very interesting investigations on the subject of depreciation in connection with the growth of the plant are published under the title "Growth and Depreciation," by Julian Loebenstein in the 1916 Transactions of the A. I. E. E., pages 1389 to 1407.

11	15	80	10	110	30
12	12	92	10	120	28
13	5	97	10	130	33
14	3	100	10	140	40
15	..	100	10	150	50

Note.—Commencing at the end of the 12th year the second replacements begin for which corresponding amounts are taken out of the fund. As the second replacements are not considered in this table, the values of Column VI beginning with the 12th year are slightly too high.

The maximum amount ever contained in the replacement fund is then 62% of the net replacement value and this maximum occurs in the 7th year. As shown above, the replacement fund is generally reduced in the course of the following renewal periods to the limit of 10%, so that 52% are set free.

It is very interesting to observe that the transition from the 62% to the 10% is not a steady reduction but is made up of oscillating increases and decreases. Column VI of the above table shows this tendency very clearly. The oscillating character of the decrease is still better brought out by the following considerations: Assuming, for instance, the first renewal ("renewal of the first order") to be spread out over four years from the ends of the 8th to the 12th years, inclusive, the first poles will have to be replaced at the end of the 8th year while others will last as long as 12 years. Now, some of the most short-lived poles (8-year poles) will be replaced by equally short-lived ones. This may be an accidental coincidence or the local conditions may be so unfavorable that in that location the renewed poles will generally require replacement after every 8 years; at any rate, the period of the second replacement of poles will begin at the end of the 16th year. On the other hand, some of the most long-lived poles (12-year poles) will last another 12 years after replacement before a third pole has to be installed in that locality. Thus the second replacement period is spread out between the ends of the 16th and the 24th years—that is, over 8 years as against 4 years of the first replacement period. Following the same line of thought further, we get the data of Table 2.

TABLE 2.

Replacement.	After	Years Duration.
1st	8th to 12th year	4
2nd	16th to 24th year	8
3rd	24th to 36tn year	12
4th	32nd to 48th year	16
5th	40th to 60th year	20

Since in every renewal period the same total number of poles has to be replaced, namely 100%, and as the renewal period spreads out over greater and greater lengths of time, it is obvious that, as the renewals progress, less and less poles are to be renewed in every year as far as one certain order of renewals (first, second, third, etc.) is concerned. On the other hand, the renewals of different orders overlap more and more. For instance, in the 34th year we have a number of poles to be renewed for the third time and others for the fourth time (see third and fourth lines of Table 2). These conditions are shown in Fig. A. The lower part shows how around each renewal period (10th, 20th, 30th, etc., year) renewals have to be made and how the lengths of the renewal periods spread out from one period to the next, whereas the number of renewals of the same order to be made during one certain year decreases as time goes on. The upper part of Fig. A then shows the sum of the renewals of all orders in every year and demonstrates clearly the fluctuations with decreasing amplitude (damped oscillations), converging to the 10% limit[2].

The interesting subject of depreciation is sufficient for a treatise in itself, but the above remarks are all that is considered necessary for the scope of this series of articles.

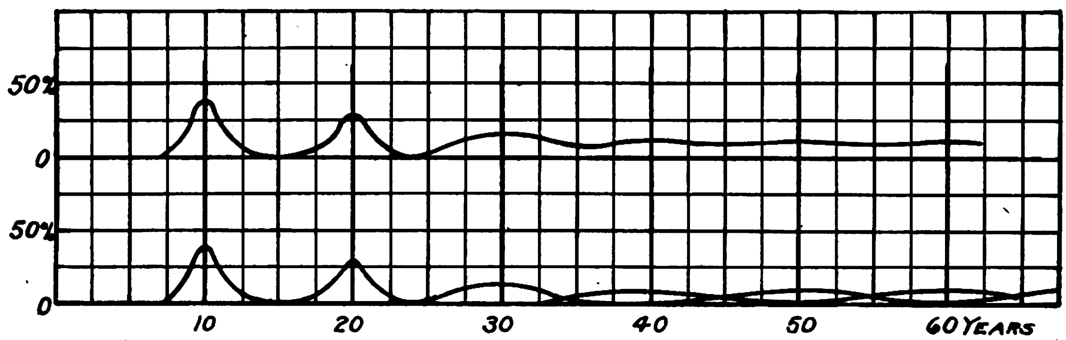

Fig. A.—Renewals of Wooden Poles Having an Average Life of 10 Years, Showing the Overlapping of the Successive Renewals (Lower Curve) and Their Sum (Upper Curve).

Insert IV—Appendix to Footnote of Section 24.

The Influence of the Central-Station's Capacity (Peak Load) on the Operating Expenses.

The example of Section 24 deals with a four-hour load of 5000 kw. and a 20-hour load of 200 kw. every day, and it is assumed that to carry this load a 5000-kw. generator would be installed.

We will, of course, try to improve on this and choose the size and the number of the generators in such a manner that a better 24-hour efficiency results. Other factors beside the efficiency curves also take a part in this problem; for instance, the reserve capacity, changes of load to be expected in future, the prices of generators of different sizes, the value attached to efficiency of generation as compared to savings in the capital invested, etc. The price of the fuel, oil, etc., will in its turn influence the relative value attached to the efficiency of generation and we might continue this analysis of influencing factors until we arrive at the mood in which the designer of the plant found himself when he made this decision about the size of the sets and whether at that time he happened to take a more or less optimistic view of the future growth of the plant, etc.

Assuming that we could be fairly positive about the constancy of the load curve in the future, special investigations might show that it is advisable to install two units of 5000 kw. (one of them as reserve) and one of 200 kw., or possibly three 2500-kw. sets, or some such combination. Now comparing, for instance, the first one of these two combinations ($2 \times 5000 + 200$ kw.) with the 1000-kw. set for uniform 24-hour service (see Section 24) it is evident that the efficiency will probably be greater than at uniform 24-hour service, because the bulk of the energy (20,000 kw-hr. or more than 83%) is generated by an economical 5000-kw. generator at full load—that is, by a generator five times greater than in case of the uniform 24-hour service, whereas less than 17% is generated by a (fully loaded) generator only one-fifth as large (200 kw.) as in case of the uniform 24-hour service. This means that the demand will have a *negative* influence on the fuel and oil consumption; in other words, the larger demand will result in a *reduction* of the fuel and oil cost. (The same will probably be true for the 3×2500-kw. combination.)

This seems peculiar. In the first instance [using 5000-kw.

[2] M. D. Cooper, of the National Lamp Works, has made interesting investigations on a closely allied field, the replacement of burnt-out incandescent lamps (Electrical World, Jan. 12, 1918, pages 93 to 95) in which he shows that the number of renewals of lamps installed at the same time and always burning simultaneously is subject to periodic fluctuations until, after a number of lamps have burned out in each socket, the stable condition is reached.

units throughout (Section 24)] we saw that an increase of the peak load from 1000 to 5000 kw. resulted in an *increase* of the fuel, etc., cost and now the same change of the peak load results in a *decrease* of these costs. The explanation is that a certain portion of the fuel, etc., cost is neither proportional to the demand nor to the energy consumption, but depends on some other elements which are not among the three fundamental items considered in our system of cost computation (compare Section 10). A portion of the fuel consumption depends, for instance, on the shape of the load curve, another portion on the size of the machines, etc. We try to apportion this part of the fuel cost somehow into the three items, just as we squeeze in the salaries of the executive officers, the advertising expenses, etc., somewhat sacrificing accuracy for simplicity and practicability, as explained in the general discussion of costs. The result of these little inaccuracies, which are entirely permissible, are little inconsistencies as the one just quoted above—the relation of the demand and the cost of fuel. To be exact we would have to say: Under the given conditions with regard to changes of the load curve, size of machinery, etc., a certain given portion of the fuel, etc., costs is proportional to the maximum demand and the factor of proportionality has a certain given—positive or negative—value. More particulars about this question will be given in Insert VIII about the determination of the numerical values of the three items of cost.

Insert V—Appendix to Section 25.

Approximations Made to Compute the Demand Cost of the Plant.

The approximating assumptions which permit us to set the demand cost of an electric plant as proportional to the peak load of the plant (see Section 25 and footnote 2 of Section 17) are shown in comprehensive form in the diagram of Fig. B. These approximations bring about much less inaccuracy than would seem at first sight, because we have to deal always with the changes produced in one *individual* central station only by the changes of its peak load and these latter changes remain within certain limits during a given period.

Thus, for instance, if the peak load of the central station increases from 5000 to 6000 kw. in one year, the other conditions, such as the geographic distribution of the load over the territory of supply (approximation 3), or the percentage of reserve capacity, etc. (approximation 1) will not have to be changed very materially. If, however, these conditions do vary to a large degree in the course of years, this will simply mean that the factor of proportionality—that is, the annual capital charges per kilowatt of peak load—will have to be changed.

Supposing, for instance, that in a certain territory the use of electric service is not very widely spread; then the copper section of the lines is not fully loaded (because the lines must have a certain minimum of copper section for mechanical reasons). If now the use of electric service becomes more general in that town the wires will first become fully loaded and then we will have to string additional wires, but the existing poles can be used for the new wires, so that the cost of the lines does not increase proportionally with the peak load. Larger generator sets will be installed, which cost less per kilowatt of capacity than those originally installed. For these and many other reasons the capital, and consequently the total annual capital charges, will under these conditions grow more slowly than the peak load does. Yet we assume that they grow at the same rate, for a number of years at least—that is, that they remain proportional to the capital. If the discrepancy in the course of the years becomes too great we simply change the factor of proportion-

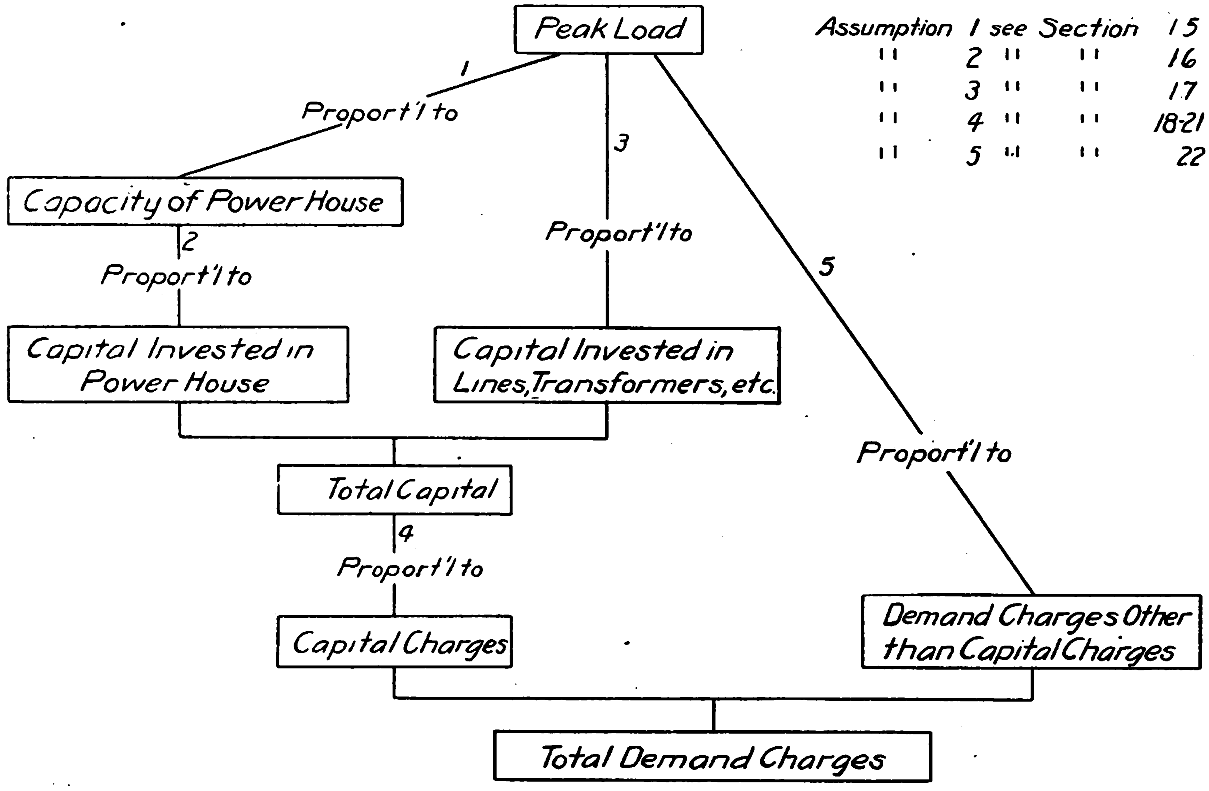

Fig. B.—Diagram Showing Assumptions as to Proportionality of Demand Charges to Peak Load.

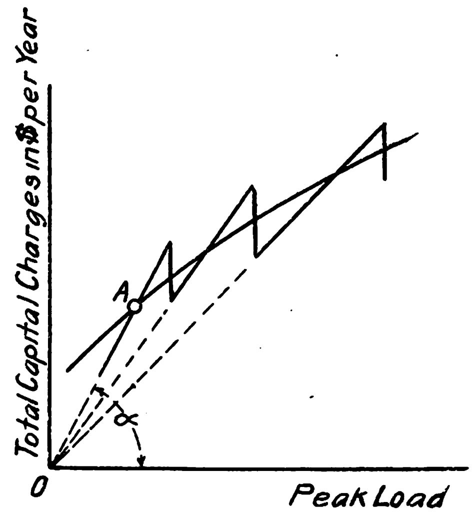

Fig. C.—Relation of Capital Charges to Peak Load.

ality—that is, we change the number of dollars per kilowatt per year to another one for the following period.

Readers who are familiar with the elements of graphic representation may get further illumination on this point from Fig. C. (An example of the principles of graphic representation employed therein will be contained in Insert XII on Step Meter Rates.) The central station's peak load is stepped off on the axis of abscissae (horizontal) and the ordinates give the corresponding total yearly capital charges per year, in dollars per year. If we connect a certain point *A* of that curve with the origin *O* of co-ordinates, the angle α between this connecting line and the axis of abscissae will be the greater the greater the capital charges per kilowatt of central-station peak load ("unit capital charges") are. (Readers who are familiar with elementary mathematics will understand that the unit capital charges are given by tan α.) Assuming the unit capital charges as being constant means that we replace the curve of the actual unit capital charges by a straight line starting from the origin with an inclination depending on the size of the assumed constant unit capital charge. If this angle of inclination is chosen properly—that is, if the value for the constant unit capital charge is chosen properly—the straight line will more or less closely follow the curve, at least for a certain distance, because the curve must necessarily rise from left to right. Where the deviation of the straight line from the curve becomes too great we substitute another straight line. This means that when the peak load in the course of the growth of the central station becomes so great that the constant unit capital charge used so far becomes too inaccurate, we revise the calculation of the unit capital charge and substitute a corrected value.

In normal times this revision will always be a revision downwards, owing to the smaller unit capital which is necessary for a large plant. But in times of war, or when money is very scarce, etc., it is conceivable that in spite of the growth of the plant, the unit capital charges may rise.

(To be continued.)

TELEGRAPH SYSTEMS IN THE UNITED STATES.

Census Bureau's Report for 1917 and the Five-Year Period 1912-1917—Commercial Wire and Wireless Telegraph Systems—Telephone Train Dispatching.

According to a report just issued by Director Sam L. Rogers, of the Bureau of the Census, Department of Commerce, the 21 commercial land telegraph systems in the United States in 1917 operated 241,012 miles of pole line, comprising 1,888,793 miles of wire; sent 151,725,238 messages; and employed 47,227 persons, to whom were paid salaries and wages amounting to $36,392,140. This report, which is issued under the title "Telegraph and Municipal Electric Fire-Alarm and Police-Patrol Signaling Systems," was prepared under the supervision of Eugene F. Hartley, chief statistician for manufactures, and is the fourth of a series of quinquennial reports on the telegraph systems of the country.

The pole-line mileage in 1917 was less by 2.6% than in 1912, but was greater by 0.6% than in 1907. The wire mileage, however, showed an increase of 4.1% as compared with 1912 and of 19.7% over 1907. The increase in the number of messages was much greater—45.7% during the last five-year period and 53.1% during the ten years from 1907 to 1917. The number of employes increased by 39.2% between 1912 and 1917 and by 84.9% during the period 1907-17, and the corresponding percentages of increase in their salaries and wages were 59.2 and 124.2.

The number of telegraph offices in 1917 was 28,-865, a decrease of 6.2% as compared with 1912 and of 0.7% as compared with 1907. The total income from telegraph traffic was $91,312,567, an increase of 74.5% over 1912 and of 140.8% as compared with 1907; the income from all other sources was $1,641,803; the total expenses, including charges for depreciation and sinking funds, were $80,828,970, an increase of 52.9% over 1912 and of 111.4% over 1907; and the net income was $12,125,400, an increase of 253.4% as compared with 1912 and of 113.7% over 1907. The par value of the outstanding capital stock of the companies was $106,360,237, a decrease of 1.7% as compared with 1912, but an increase of 4% over 1907.

The foregoing figures relate only to commercial telegraph companies, and thus exclude the wire and pole line wholly owned and operated by railroads, and also exclude the equipment and telegraph business of the various press associations which lease and operate wires for dispensing news.

The Postal Telegraph-Cable Company transacts some little telephone business in addition to its telegraph business. Its development of long-distance telephone service has been particularly rapid in the South and Southwest.

During the five-year period 1912-1917, the printing telegraph came into extended use by telegraph companies, press associations, and railroads. The printing telegraph consists essentially of a sending instrument, equipped with a keyboard similar to that of a typewriter, electrically connected with a receiving instrument in such a manner that the latter automatically reproduces what is typewritten on the sending instrument. Without the printing telegraph it would have been difficult or impossible to handle the increased telegraph business during the World War.

A special feature of the report, relating to train dispatching, is of some interest. The first installation of telephone and selector equipment for train dispatching was completed on the lines of the New York Central Railroad in October, 1907. The use of the telephone for this purpose has increased rapidly. The report shows, for 1917, 105 lines employing this method of train dispatching, as against 42 in 1912. The mileage of telephone pole line for train-dispatching purposes was 95,268, an increase of 67.6% as compared with 1912; and the mileage of wire was 201,662, an increase of 55.7% over 1912. The total line mileage of railroads reporting the use of telephones for transmitting train orders in 1917 amounted to 110,404. It is asserted that not a single accident has resulted from the use of telephones in train dispatching.

All the wireless telegraph systems in the United States were taken over by the Federal Government under authority of an executive order issued April 6, 1917, for which reason the figures for 1917 give little indication of the increase in commercial wireless telegraph operations during recent years. The systems reported for 1917 numbered 3, as compared with 4 in 1912 and 5 in 1907; and the number of tower stations was 63, as compared with 74 in 1912 and 117 in 1907. The number of messages handled prior to April 6 was 122,244. No exact record of the number transmitted during the period of Government operation is available, but it is roughly estimated that 330,-000 messages were handled between April 6 and Dec. 31, 1917. This number, added to that already given, would make a total of more than 450,000.

The total income and the net income increased greatly. The former aggregated $1,385,060 in 1917, representing a gain of 107% over 1912 and of 1197% over 1907; and the latter amounted to $609,526, as compared with a net income of $4738 in 1912 and a net deficit of $53,538 in 1907. The employes numbered 586, a decrease of 38.8% from the corresponding number in 1912, but an increase of 233% over the number for 1907; and their salaries and wages aggregated $461,402, an increase of 17.2% over 1912 and of 464.2% over 1907.

Contractor-Dealers Hold Enthusiastic Annual Convention

Proceedings of 19th Annual Convention of National Association of Electrical Contractors and Dealers Held in Milwaukee—Merchandising Principal Topic — Repair and Labor Problems also Discussed

BETTER MERCHANDISING with a view of increasing the use of electric apparatus and improving conditions in the electrical contractor-dealer field was the principal topic of discussion at the recent annual convention of the National Association of Electrical Contractors and Dealers held in Milwaukee, July 16, 17 and 18, although many other topics of interest were also presented and fully discussed. The remarkable growth of the retail electrical store idea during the past two years, largely through the efforts of W. L. Goodwin and his associates, is largely responsible for the enthusiasm and keen interest displayed in this subject and it is evident that the advancement in this direction will continue, that more and better retail electrical stores will be established and all will be conducted in accordance with the best and latest merchandising practices. This was also the subject of many interesting addresses by prominent speakers, who described and explained not only the fundamentals of merchandising but the proper conduct of a retail store and offered many valuable suggestions to merchants and prospective merchants.

The proper relationship between employer and employe that will make it possible for both to live and work together in harmony and progressive efficiency, was another principal topic and one that in its discussion, better than any other, demonstrated the progress that has been made by the association and its members. This subject, which finally resulted in the adoption of the "Declaration of Principles" published further on in this report, was discussed freely and with considerable spirit at the meetings of the Executive Committee and on the floor of the convention on Friday afternoon. In addition, a very interesting and instructive address on this subject was delivered by H. C. Metcalf, Ph. D., Bureau of Industrial Research, New York City. In the discussion the membership showed that it has advanced far beyond its former standing and is ready and able not only to take its place in the world of business but to be the leaders in that sphere.

The meeting of the Repair and Sale of Used Apparatus Section also proved of great interest to those members engaged in that line. This meeting was the first of its kind ever held by the association, but, from the results obtained and the interest displayed by those who attended this meeting, there is no doubt but that they will be a regular part of future convention programs.

Throughout the entire convention the more than 400 members who registered exhibited the keenest interest in the proceedings and in the discussions and by constructive criticism and suggestions did much to make this the best convention the association ever held. And, they evidently succeeded for the consensus of opinion among the older members seemed to be that this was really the best convention ever held and that it would rank high among all electrical conventions.

Meetings on Opening Day

A complete report of the sessions on the opening day, Wednesday, was published in our July 19 issue. At the morning session on this day the delegates were welcomed to Milwaukee by Cornelius Corcoran, acting mayor of the city, to which W. Creighton Peet, chairman of the association responded. In his address Chairman Peet briefly reviewed the activities of the association during the past year and described the work now under way. Through co-operation with the other branches of the industry the Bureau of Education and Research is now fully developed and is expected to begin its labors in the field shortly. Other committees have also been very active, particularly since the armistice was signed, which has resulted in a large amount of work for the good of the association and its members being accomplished.

Franz Nielsen, counsel for the association, then spoke on "Co-operation in Business." He described the growth of the co-operation idea and the many advantages which it offers to the contractor-dealer in his relation with other merchants and the other branches of the electrical industry. He spoke of the work that the association has done to further this idea and the remarkable results that have been obtained, as evidenced by the conference held on Monday evening to complete the arrangements for the educational campaign. In closing he urged the members to take a more active part in the work of the association and to assist its officers, willingly, in every possible way.

In the afternoon Frank Stockdale, of Chicago, delivered a very interesting address on "Keeping Up With Rising Costs." In this address, Mr. Stockdale carefully analyzed merchandising, particularly as applying to the electrical retailer. Many valuable suggestions for the retail merchant in the conduct of his store were brought out and many of his problems were explained. He particularly emphasized the need for keeping a proper cost accounting system in order that the dealer may keep a check on his business. The cost accounting system that has been developed by the association, he stated, was one of the best and simplest he had ever seen and recommended its adoption by all of the members.

Albert Uhl and E. L. Morley, representatives of the Chicago Electrical Estimators' Association, then explained the work that has been done and is being done by that association. Mr. Uhl described the estimating forms that have been developed and which offer many advantages in making and tabulating estimates for electric wiring. Several minor changes have recently been made in these forms which render them much more convenient than they formerly were. The forms were illustrated by lantern slides which added greatly to the effectiveness of the address and brought out their many advantages very clearly. Mr. Morley described the work that the association has done in solving the problems of overhead on construction work which has already received a great deal of attention among electrical contractors. These lectures brought out considerable discussion which clearly indicated the interest which the members take in such work and the value of the results obtained by the Estimators' association.

In the evening a reception and dance was held at the Hotel Pfister which was very well attended and proved to be a very enjoyable occasion.

"Goodwin" Day at Waukesha Beach.

The session on Thursday, which was styled a "Goodwin" day as a mark of appreciation to W. L. Goodwin of the General Electric Co., and his untiring efforts in behalf of the association, was held at Waukesha Beach, a beautiful resort located about 25 miles from Milwaukee, and an especially fitting place for such an affair.

The opening address on this occasion was delivered by J. H. Moss, former president of the Milwaukee Association of Commerce, on "Americanization." In this address, Mr. Moss emphasized the importance of naturalizing the foreign element in this country and the dangers of neglecting to do so. Materially, it is estimated that a saving of two billion dollars annually will result from such naturalization as the education thus acquired will greatly increase the earning power of these inhabitants. As their education could be accomplished for only a small part of this sum it is surely worth the effort. Politically and morally the results would also be highly desirable, particularly at this time when the country faces a crisis in many ways and as the number of illiterate foreign born is steadily increasing. In Mr. Moss' opinion there are two phases to this problem, immigration and education, which must be studied and suitable remedies applied if the proper solution is to be arrived at.

In introducing W. L. Goodwin, who was the next speaker, Chairman Peet took occasion to thank both Mr. Goodwin and Samuel A. Chase of the Westinghouse Electric & Manufacturing Co., for their unselfish efforts in the work of the association.

At the opening of his address on the fundamentals of merchandising, Mr. Goodwin heartily endorsed the new educational campaign that has been developed by the association and which will be put into effect shortly. The conference held on Monday evening to complete the arrangements for this campaign and which was attended by representatives of every branch of the industry, proved conclusively he stated, that this campaign has been the means of planting the germ of co-operation in the electrical industry. He also described the vast improvement that has been made by the contractor-dealer in his business affairs during the past two years and which he especially noticed in his recent trip around the country, particularly in regard to the improved credit and moral standing of these firms. In this way the contractor-dealers have already proven their ability.

There is still a lack of knowledge of merchandising, however, in spite of the fact that 350 retail electrical stores have been opened during the past two years with but one failure. In this way the electrical men have set a pace in merchandising and are fast regaining the business and although they do not wish to drive others out of this field they do desire to establish certain practices which if possible, will preserve the electrical business to the electrical people.

Merchandising is simple if properly understood and the need of natural ability to become a successful merchant is only true to a certain extent. The greatest need at the present time is for good stores and the next is to improve the packing of merchandise so that commodities may be standardized and a well ordered stock maintained. To accomplish this several manufacturers have changed their methods of packing their products, and very desirable results have already been obtained.

Delegates at 19th Annual Convention of National Association of Electrical Contractors and Dealers Assembled on Auditorium Steps in Milwaukee, Wis.

The location and the selection of goods salable in that community are very important items in the establishment of a retail store. There is always one class of merchandise that satisfies the local demand in any community and the dealer should handle that class rather than any other, even if the discount on it is not as great as in the others. For there is no profit until the goods are sold and larger discounts do not always mean larger profits. Nor should the dealer attempt to handle every concievable line but should concentrate on one line that he is sure will meet the requirements of his trade. Store employes with a knowledge of electricity and electrical apparatus are also necessary if the best results are to be obtained and the dealer should keep posted on his business by reading carefully the electrical trade papers. In this respect Mr. Goodwin advised every dealer to read a trade paper at least 15 minutes every morning if he is to keep abreast with the times.

There is also a tendency on the part of many electrical dealers to argue with their customers, which should always be avoided. No sale can really be considered completed until the customer is satisfied which shows particularly the value of only handling goods of known merit as the customer will usually accept goods on the dealer's recommendation. Another feature that must be appreciated is the value of attractive window displays. The most desirable store is of no value without a window and likewise the best window is worthless unless it is well decorated and attractive. Proper window displays he considers are of much more value to the dealer than larger discounts from the manufacturers.

The most important item retarding the growth of such stores is the lack of standardization of receptacles and wall outlets for the use of appliances. Due to the petty jealousies of the various manufacturers of such apparatus, practically every line requires a different type of outlet and receptacle which means that the customer must have several cords for the appliances in use. This of course retards the use of such appliances. The contractor-dealers, however, can force the manufacturers to standardize such connections, just as the lamp bases have been standardized and should take steps as soon as possible to bring this about.

Mr. Goodwin also urged the contractor-dealers to establish card records of prospective customers such as are used in many other industries, particularly by the piano and other musical instrument houses and mail order firms. These records could also be exchanged among the various dealers in the town and the central-station companies to advantage.

In order to assist the contractor-dealers in every way in the operation of retail stores and to encourage the opening of such establishments a lecture has been made up by the General Electric Co., in co-operation with the Westinghouse Electric & Manufacturing Co., which was given by J. A. Corcoran of the former company. In introducing Mr. Corcoran, Mr. Goodwin invited the criticism of those present, for it is only by such criticism that the dealers can secure the fullest results.

Mr. Corcoran's lecture was very interesting, bringing out many valuable suggestions for the proper conducting of a retail store which were illustrated with many charts and other properties that added a great deal to its effectiveness. Throughout the whole lecture there runs a strain of humor which serves to bring the suggestions out even more forcibly.

Sales, he explained, are the most important part of retailing and it is therefore very desirable for the dealer to know the extent of the possible field for electrical merchandise. There are at present 15,189,000 homes in this country not wired for electric service, while 5,500,000 are wired and the amount already spent in wiring houses is $275,000,000 against $759,459,000 which must be spent to wire the remainder. To accomplish this wiring of existing homes he estimates would take 10,000 contractors of average size, 20 years. The average percentage of income that the families of this country spent for electric current is 1/10 of 1%.

In order to secure the proper proportion of the business of the country the electrical dealer must first consider his points of contact with the public. There are five principal contact points,—store exterior, store interior, window display, publications and advertising. Next, he should appreciate the motives which prompt a purchase or buying motives of which there are also five—gain, necessity, pride, foresight and luxury. Every purchase is prompted by one of these motives alone or a combination of them. Memory is another feature that should be cultivated by the dealer both for himself and his customers, and this depends on association, repetition or intensity. He should also know the fundamentals of advertising,—interest, desire, action and in this he should remember that the nerves leading from the human eye to the brain are four times as great as those from the ear.

In choosing the location for a store the dealer should study the situation carefully and endeavor to locate along the principal trade stream. Such trade streams will usually be found near the local post-office, a large department store or the local central-station company's office and follow along the street in certain directions. However, it often happens that one side of a street affords a much better location than the other or the trade stream may stop at a certain point and turn back leaving the store but a few feet further on out of its influence.

The exterior of the store should be made as attractive as possible. This applies not only to the windows, sidewalks and doorway, but the upper floors as well, for the prospective customer sees the outside of the store first which also includes these upper floors. and their windows. The sidewalk in front should be free from any obstructions, such as trap-doors, etc., and the entrance should always be at the street level.

The most important factor of the store interior is the employes. The salespeople should know something about electricity and electrical apparatus and the stock in the store and the dealer's policies must be thoroughly understood. In the arrangement of the interior two plans may be followed, the jewelry and the hardware store styles. The former, which consists of a row of cases or shelves along the walls and a glass U-shaped counter in the center is preferable in some places but the latter with the sales counters along the side walls backed up by shelves is more generally used. In the selection of colors for interior displays and decorations considerable care should be taken. Nearly every color has some advantage which renders it especially fitting for certain displays, for example: red for intensity, blue suggests coolness, and grey is good for quality goods. Lavender, however, is only good for funerals and should always be avoided. Every sale should be accompanied by a demonstration in order to enable the purchaser to properly understand the appliance and its operation. The telephone is another contact point in the interior of the store which can be used to advantage by the enterprising dealer. In addition the personality of the proprietor, the outside employes, the firm's trucks, lantern slides, etc., are important factors of contact with the public.

Under the heading of publications as a point of contact come the mailing lists, distribution of posters and signs, stationery, calendars, advertising pencils, car cards, which are very effective but also rather expensive and display cards and price tags, especially. A great many dealers do not appreciate the value of showing the price of all articles on display. If the price is not marked the public assumes it to be high, whereas, if the price is plainly marked they assume it to be a bargain and are more interested.

In newspaper advertising the text should be timely, forceful, direct and truthful. It should be neat and attractive in appearance and if possible, should always have a distinct white border around it which causes it to stand out better. Special attention should also be given to the position of the advertisement.

Window displays are of course of vital importance. Such displays should be changed frequently and made as attractive as possible, with special attention to the window lighting. As in interior displays lavender should always be avoided. In illustrating this point miniature display windows were used and the different types of displays shown.

Following Mr. Corcoran, Mr. Goodwin again spoke and requested the frank criticism of those present on any of the ideas presented. The job of merchandising, he explained, was big enough for all to attempt and the field was far from saturated.

In the afternoon a number of athletic events were held in which all present were invited to participate, and a number of valuable prizes were presented.

Repair and Sale of Used Apparatus Section.

On Friday morning two parallel section meetings were held, one by the Repair and Sale of Used Apparatus section and the other by the Merchandising and Fixture Dealing section. A. L. Swanson of Evansville, Ind., presided at the former and Jos. A. Fowler, of Memphis, Tenn., at the latter.

The first address delivered before the Repair and Sale of Used Apparatus section was delivered by A. Penn Denton, of the Denton Engineering & Construction Co., Kansas City, Mo. Mr. Denton's address is reproduced substantially in full in another section of this issue.

This was followed by a paper by A. O. Kuehmsted of the Gregory Electric Co., Chicago, on the "Methods of Determining the Value of Burned Out Apparatus." This concern is one of the oldest and largest handling used electrical apparatus and Mr. Kuehmsted's talk was largely the result of its experiences in this line. The methods of determining the value of any burned out motor or generator, he said, are comparatively simple if sufficient data are provided. The Gregory company has collected these data from three sources and from these data has compiled indexes which have proven of great value in this work. The first of these indexes contains information gathered from catalogs published by the various manufacturers of this equipment which lists the weight and size of the apparatus together with its characteristics.

The second is a card cost system in which is listed the cost of rewinding armatures or fields or refilling and connecting commutators. Each card shows the cost of the raw material, the credit for scrap material, and the labor cost. From these costs on past operations the company can easily ascertain the approximate cost of similar repairs to these machines. It may be of interest to note that the cost of rewinding armatures or fields is practically the same for all makes of the same size and type but the cost of refilling commutators varies in the products of the different manufacturers.

The third index consists of an up-to-date schedule of standard machine prices, the cost to the dealer, the jobber's cost, etc., and from this is based the price which shall be paid for a machine in good condition. However, this price will vary according to the actual age of the machine and whether there is any demand for it or not.

By using these systems the company is able to estimate what any machine is worth. If it is in good condition the offer can be made from the price schedule. If it is in very poor condition, its scrap value can be ascertained by referring to the catalog index which lists the weight of the iron and steel in that particular piece of apparatus. If the commutator needs refilling or the armature or field needs rewinding, the cost of making such repairs can be determined and is deducted from the amount offered for the apparatus.

The company has found that it can afford to purchase used machines for resale that have only one part needing replacement, that is, if the commutator needs refilling, or the armature rewinding or the field rewinding. However, it cannot afford to buy a machine for resale that will require the replacement or repair of any two of these parts except under very unusual conditions, for the repair cost would be too great and therefore only the scrap value can be allowed.

In the discussion of this subject many valuable points were brought out. For example, it was shown that the average price of a second-hand machine in good condition will average 60 to 75% of the cost of a new machine under ordinary circumstances. It was also pointed out that the overhead expense of conducting such enterprises will be from 33⅓ to 50% of the cost.

Mr. Kuehmsted also gave some pertinent advice on guarantee polices which caused considerable favorable comment among those present. The dealer's reputation, in his opinion, is the best guarantee to be given and to guarantee the performance of any apparatus for a certain length of time is inadvisable. The Gregory company ships apparatus which it guarantees to be in good condition when installed and will refund the purchase price and take back the apparatus if it proves unsatisfactory. It will not, however, make any rebate for minor claims arising after the apparatus has been in service.

Following Mr. Kuehmsted, C. M. Jamison, of the Milwaukee Railway & Light Co., explained the policies of that company with regard to appliance repairs. The merchandising department of that company, Mr. Jamison stated, is conducted for profit and he believes its influence is of assistance to the local dealers as it also increases their sales. The minor appliance repairs are made on the customer's premises for which a charge is made. The large repair work is done in the company's shop or distributed to the local repair firms.

Following the presentation of this paper the idea of establishing central repair shops was brought up and discussed. Such shops could more easily carry a stock of parts for all types of appliances than the individual repair shop, for the volume of business would be much greater.

Merchandising and Fixture Dealing Section.

The first speaker at this session was John G. Learned, chairman of the Commercial Section of the National Electric Light Association, who spoke on "Complete Electrical Equipment for the Home." Mr. Learned explained in detail the plans for a nation-wide educational campaign for the purpose of creating a greater demand for complete installations of wiring and appliances in the home which have been developed by the Commercial Section. Mr. Learned's address will be reproduced in full in a later issue.

Phil Polacheck of Milwaukee then described the "Arrangement and Conduct of a Retail Store." Mr. Polacheck recommended that in the electrical retail store the different departments be separated from each other but should be arranged so that any purchaser entering the store can see at a glance all the kinds of merchandise offered for sale. Such departments, for example, as those that sell ordinary supplies such as fuses, sockets, lamps, etc., appliances and fixtures should be distinctly separated but not isolated. Many interesting and valuable suggestions were brought out in this paper and in the very lively discussion that followed. In this way the value of the various methods of arranging store were clearly shown.

Following this, a paper on the "Relations of the Dealer to the Public in Merchandising" was read by J. R. Tomlinson of Portland, Ore. This paper will also be reproduced in an early issue.

A. L. Oppenheimer of Cleveland, Ohio, delivered an address on the features of fixture business as a part of retailing in which he clearly explained the value of selling lighting fixtures as an adjunct to the sale of appliances and other electrical goods, and described the difficulties frequently met in such endeavors.

Afternoon Session.

At the afternoon session, H. C. Metcalf, Ph. D., of the Bureau of Industrial Research, New York City, delivered a stirring address on "Human Relations in Industry." The subject was especially fitting coming as it did immediately before a discussion on this subject by the association.

Doctor Metcalf described the growth of the human relations idea industry which has resulted in the establishment of personnel or similar divisions in many large concerns throughout the country. In this respect, he stated, the interests of the employe, the employer and the public are practically concurrent if not identical. The loyalty of its employes is a great asset for any concern which, of course, can best be secured by realizing what the employe wants and can reasonably expect to get from his employer. In his opinion, what the employe wants is, first, a knowledge of the firm and his work so that he may be able to select a firm to work for just as the modern employer selects the proper man to work for him; second, security of employment; third, a living wage; fourth, a share in the management; fifth, his own status in the company. The employe also wants the right to organize, but such organizations should be for the purpose of working together. On the other hand, the employers should be willing to experiment in democracy, which means participation. The problem, as Doctor Metcalf sees it, is largely an educational one and ability at the top to recognize and deal with it is the only limit to the expansion of business. However, to establish justice in work relations is the greatest problem to which business can address itself.

During the course of his address Doctor Metcalf referred to "Declaration of Principles" that had been drawn up and which was about to be considered for adoption. In his opinion, this was a big step in the right direction and he complimented the members and the association for their efforts to solve this problem.

The adoption of the "Declaration of Principles," however, met with considerable opposition from some of the members who were skeptical of its purpose and feared lest it should offend those members who do not employ union labor. After considerable lively and interesting discussion in which everyone was given an opportunity to express his opinion and during which an enthusiastic appeal for its adoption was made by Mr. Goodwin, the association voted to adopt this code. The resolution from the Executive Committee and the "Declaration of Principles" as adopted are as follows:

Resolution from Executive Committee to the Nineteenth Annual Convention.

Whereas, The fundamental problem which confronts the business world today is the necessity of establishing relations between men that will make it possible for them to live and work together in harmony and progressive efficiency, and

Whereas, The solution of that problem can be found only through mutual application of infinite patience by employers and employes in co-operative research and education, and

Whereas, No agency for such co-operative work by employer and employe now exists in the electrical contracting industry, and

Whereas, In view of the conditions recited, it is the opinion of the National Executive Committee that the time has come when the National Association of Electrical Contractors and Dealers must change its position of regarding matters of relationship between employer and employe as beyond its legitimate field of activity, and face the fact that the issues now arising and which will continue to arise, involving the very life of industry, and therefore the life of the community, can be settled peacefully only through the faithful co-operation of employers and employes, whose interests in the productive effort are common and inseparable; now, therefore,

Be It Resolved, That the National Executive Committee approve the "Declaration of Principles" presented herewith, and

Be It Further Resolved, That the Executive Committee refer the said Declaration of Principles to the National Association of Electrical Contractors and Dealers, in convention assembled, approve it, and authorize the Executive Committee to act as it may deem best in applying the principles enunciated with a recommendation that a special committee be appointed to act in the matter.

Declaration of Principles—Preamble.

The vital interests of the public and of employe and employer in industry are inseparably bound together. All will benefit by a continuous peaceful operation of the industrial process and the devotion of the means of production to the common good.

Principles.

1. The facilities of the electrical industry for service to the public will be developed and enhanced by recognizing that the overlapping of the functions of the various groups in the industry is wasteful and should be eliminated.
2. Close contact and a mutually sympathetic interest between employe and employer will develop a better working system, which will tend constantly to stimulate production while improving the relationship between employe, employer and the community.
3. Strikes and lockouts are detrimental to the interests alike of employe, employer and the public and should be avoided.
4. Agreements or understandings which are designed to obstruct directly or indirectly the free development of trade or to secure to special groups special privileges and advantages, are subversive of the public interest and cancel the doctrine of equality of rights and opportunity, and should be condemned.
5. The public interest is conserved, hazard to life and property is reduced, and standards of work are improved by fixing an adequate minimum of qualifications in knowledge and experience as a requirement precedent to the right of an individual to engage in the electrical construction industry, and by the rigid inspection of electrical work, old and new.
6. Public welfare, as well as the interests of the trade demands that electrical work be done by the electrical industry.
7. Co-operation between employe and employer acquires constructive power, as both employes and employers become more completely organized.
8. The right of employes and employers in local groups to establish local wage scales and local working rules is recognized and nothing herein is to be construed as infringing that right.

The convention closed on Friday evening following the annual dinner of the association. This proved to be a fitting finale of a most successful convention. James R. Strong, a New York City contractor-dealer, was the song leader on this occasion and although he has filled this position on many former occasions, his efforts at this time were particularly praiseworthy.

Next Convention to Be Held in Baltimore.

Requests for the next convention were received from many cities, which were backed up by the efforts of enthusiastic delegates. After considerable deliberation on this subject the Convention Committee decided to hold the next annual convention in Baltimore, Md., with Oct. 6, 1920, the opening day.

Electricity for Heat Treatment in the Steel Industry

Use for Soaking Pits, Reheating and Annealing Furnaces—Automatic Heat Treatment—Iron and Steel Institute Paper

By THADDEUS F. BAILY

President, The Electric Furnace Co.

THE introduction of electrically heated furnaces to the heating operations subsequent to melting and refining in the steel industry has experienced the slow development incident to the introduction of all radical innovations in any industry. Many of the types that will find wide application in the future, while entirely feasible, have, when offered, been met with the statement that if such an equipment was a good thing, why were they not in general use. Other types that have been in regular service for a considerable number of years whose construction and operation are much more elaborate and whose commercial advantages are no greater, are now generally accepted as the most rugged and reliable equipment for the purpose. This latter refers to electric furnaces for the annealing and heat treatment of steel.

One of these types installed some three years ago has been used exclusively since its installation for the particular material for which it was designed—namely, cast steel draw-bar knuckles—and subsequent to the installation of the first unit, a second unit of the same capacity was installed. This equipment has, since its installation, handled over 50,000 tons of material—approximately half of all the material of this character used on American railroads having passed through these furnaces.

The higher "fuel" cost for electric furnaces over fuel-fired furnaces that might have been used for the same purpose has been amply justified in commercial practice by the labor saving effected, the precision of the treatment produced, and the elimination of the rejections of parts due to defective heat treatment; the precision of the laboratory is obtained in regular plant practice.

There has been a reluctance of manufacturers generally to consider that there is a difference in cost per ton of material put through a furnace and the cost per ton of material heat treated and coming within the specifications. There has been no greater factor in changing this attitude than the conditions brought about during the war, where in a great many plants there was a wide difference between the quantity of material inspected and the quantity of material accepted. Manufacturers now are generally conceding the justness of the higher requirements for steel, and this is one of the greatest arguments in favor of electric furnaces.

Three conspicuous examples of the electric furnace for heat treating are those for Liberty motor crank shafts, over half of which were so heat treated; cast steel anchor chain, all of which was heat treated in furnaces of this character; and draw-bar knuckles, substantly half of those which are used in America being thus heat treated.

These examples are typical of the furnaces to be described in this paper adapted to other operations in the steel industry and embrace soaking pits for the soaking of hot stripped ingots, re-heating furnaces for hot blooms and billets, combination fuel and electric furnaces for the heating of bold blooms and billets, recuperative car type annealing furnaces for bars and sheets, and automatic heat treating equipments for drop forgings and castings and for the heat treatment of steel rails and similar material.

The Electric Soaking Pit.

The electric soaking pit for hot ingots is perhaps the most promising development of the electric furnace to the steel maker, as the shortcomings of the present pits—whether of the fired or non-fired type—are well known, and many troubles of the rolling mill can be traced to the present type of it.

The principal recommendation of the present type of pits, either of the fired or non-fired type, is the low fuel consumption per ton of metal soaked. This cost in a well handled pit is almost a negligible item, amounting frequently to only a few cents a ton.

However, in the larger mills, when running at full capacity, features such as lack of uniformity in temperature of the heated ingot, excessive oxidation of the ingot, etc., are often such as to quite outweigh the item of mere fuel cost, and while it is to be admitted that electric pits cannot compete with fuel-fired pits under ordinary circumstances, when heating cold ingots, the time is not far distant when substantially all modern mills rolling hot ingots will use electric pits for this part of steel mill operation.

It has been difficult to overcome the prejudices against this innovation in ingot soaking, but the advantages to be gained are so apparent and the success of electric furnaces in other similar fields has been so marked, that it will not be long until electric soaking pits will be in commercial operation.

From electric furnaces operating at the same temperature, or at even higher temperatures than that required in soaking pits, and which have been operating over long periods of time, it is apparent that the standby, or wall losses, of a typical pit adapted to hold sixteen 3-ton ingots will not exceed, as a maximum, 1000 kw. and will be expected to operate on considerably less current.

However, taking 1000 kw. as a basis, which is amply safe, and when operating on hot ingots, whose superheated interiors are sufficient to bring to temperature their colder outer shells, and operating on a soaking time of 1½ hours, the capacity per pit will be 32 tons per hour with a figure of 1000 kw. current on the furnace, the current consumption per ton of metal soaked would thus be 35 kw-hr. per ton; taking as a basis of cost of electricity in the steel mill one-half cent per kilowatt, the cost per ton of metal soaked would be 17½ cents, to which might be added a cost of 5 cents per ton for renewals and repairs, making a total cost of 22½ cents per ton for these two items.

It is to be expected that this cost for heat may be in excess of similar costs for gas-fired pits or unheated pits, but when taking into consideration that the electric pit will eliminate the roll breakages due to cold ingots, delays in the mill due to ingots unevenly heated, oxidation (thus producing a cleaner bloom and an actual saving in metal due to this elimination of oxidation, amounting to perhaps one-half of 1%),

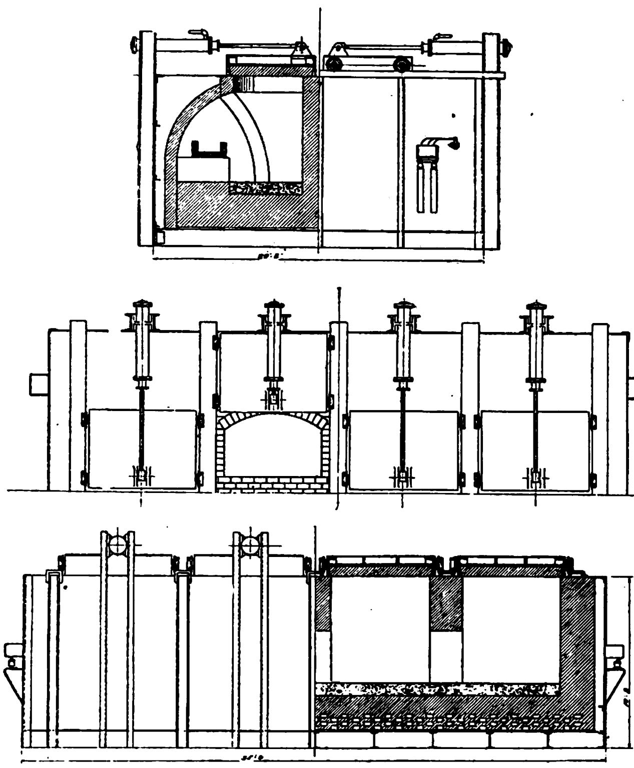

Fig. 1.—Pit Type Furnace for Soaking Ingots for Heavy Forgings and Shafts.

as well as the ability of the electric pit to save labor, it is certain that the higher cost will be more than offset by the advantages, and that per ton of metal rolled in a given period the actual cost by the use of an electric pit will be less than by other means.

Fig. 1 shows the general arrangement and character of such a pit. This pit will be provided with eight holes, instead of the usual four, and in consequence only half as many ingots will be located in each cell.

The resistance elements themselves, composed, as in all furnaces of this class, of broken carbon thrown loosely into a carborundum fire-sand trough supported on brick pillars, are located along the outer wall of each side of the pit and protected against the liability of serious accident from the ingot by being recessed some distance back from the ingot cell itself. The heat from this resistance element, it will be noted, is radiated to the circular wall of the pit and thence to the cover, the partition wall of the pit, and to the ingots themselves. The cross section of this resister element is such that there is very little difference between its temperature and the ruling temperature of the pit, and in actual practice most of the heating is done by the walls of the pit itself, rather than by direct radiation from the resistor element—this being of the highest importance in obtaining uniformity of heating.

In cases where the ingots cannot be delivered to the pit with enough heat for them to reach a high enough temperature without the addition of more heat from the pit itself, a longer time will be required by the ingots to bring them to temperature, and at the same time the capacity of the pit in tons per hour will be reduced.

But taking as a basis ingots whose average temperature would be 1800° F., requiring 300° additional for bringing them to temperature, the capacity of the pit would be reduced to 24 tons per hour, the electrical capacity of the pit increased to 1500 kw. and the current consumption increased to 60 kw-hr. per ton.

With the ingots charged at an average temperature of 1500° F., the capacity of the pit would be reduced to 16 tons per hour, and the current consumption increased to 90 kw-hr. without increasing the electrical capacity beyond 1500 kw.

Thus we have for a total of heating costs, including the renewals and repairs, and with power taken at ½ cent per kw-hr.

Material,	Cents per ton.
Hot ingots	22½
Ingots at 1800° F..............	35
Ingots at 1500° F..............	50

the final temperature in each case being taken as 2100° F.

These figures can be safely taken as guarantees and it can be expected that they will be much bettered in actual practice and operation over long periods of time.

Continuous Type Reheating Furnaces.

It is believed that this type of furnace (Fig. 2) will find wide application in the heating of cold steel for forging and rolling in relatively small capacities and in reheating steel of high quality, but where very large tonnages of cold blooms or billets are to be heated, a combination fuel and electric furnace—to be later described—will be better adaptable for such work.

The illustration on the next page illustrates an all-electric billet heating furnace.

This furnace was built for heating 3¾-in. round billets for shell forgings and while the current cost for supplying this particular furnace was high and the operating conditions not particularly favorable, nevertheless the reduction of rejections of forgings due to eccentricity, the saving of the dies due to the elimination of scale and other advantages, such as better working conditions and simplicity of control, enabled the results to compare favorably with coal-fired practice.

This furnace was of 600-kw. capacity and in actual practice handled 1½ tons of steel per hour, with a current consumption of a little over 450 kw-hr. per ton or a thermal efficiency of a little more than 50%. Under more favorable conditions, an efficiency of 66%, or a current consumption of approximately 300 kw-hr. per ton has been obtained. So that with low cost of current, which it is believed may be taken as ½ cent per kw-hr. in steel mill power costs, the "fuel" cost for cold heating in units of this size would be $1.50 per ton.

This cost will compare favorably with direct coal-fired furnaces of similar capacity and will actually show some commercial advantage when taking into consideration the saving in metal due to scaling, which may readily run several per cent and at least in average operating conditions may be taken as 2% and under the worst conditions 5%, actually observed in one or two instances.

Furnaces of larger capacity than the one described show a less favorable comparison to the electric and furnaces of smaller capacity show a more advantageous comparison with the electric furnace, and it is believed that in any case, the cost of material heated in furnaces of this size, all things considered, may be safely taken as running very close together, with the electric furnace having the advantage in greater uniformity of temperature and other incidental advantages, including a higher yield of good finished pieces.

An application that it is believed will find favor in certain steel mill operations is the use of an electric furnace for re-heating billets for finishing mills,

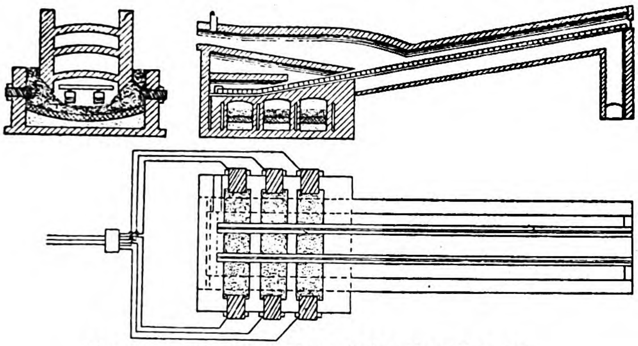

Fig. 2.—Continuous Type Reheating Furnace.

wherein the blooms or billets coming from one mill are too cold to put into the finishing mill and will require approximately 200° additional heat.

The calculations on such an equipment are as follows for a capacity of 15 tons of 4-in. square billets per hour, charged into furnaces at 1800° F. and brought to 2000° F. Such a furnace would require 800 kw. current for its operation and somewhat under 60 kw-hr. per ton of metal re-heated, and with ½ cent for power, making a cost of 30 cents per ton of metal re-heated. As an electric furnace of this character would undoubtedly save one-fourth of 1% of metal over fuel-fired furnaces, which would amount on steel worth $40 per ton to a saving of 10 cents per ton, and then taking into consideration the low efficiency to be expected of a fuel-fired furnace of this character operating on hot billets only, there would be a decided advantage in the use of the electric furnace for such an operation.

Combination Fuel and Electric Reheating Furnaces.

Where large tonnages of cold blooms and billets are to be heated, however, unless electricity can be obtained at an exceptionally low rate and fuel can only be had at a high cost, a combination gas and electric furnace (Fig. 2), wherein the earlier stages of the heating up to, say, 1800° F. are handled by fuel, and the final temperature handled electrically is perhaps the only type that can compete with the continuous fuel-fired billet heating furnace.

Such a combination would enable the preliminary heating to be done with fuel, without the danger of excessive oxidation that is present in the fuel-fired billet heating furnace, and will insure a uniformity in the heating of the billets that is not generally obtainable in fuel-fired furnaces of this type, and while there would be a small saving of perhaps 50 lb. of coal per ton of metal heated due to the lower temperature to which the billets are heated by the fuel-fired end, against this must be charged, say, 60 kw-hr. per ton of metal or 30 cents per ton of metal heated for the final stage by electricity; nevertheless, the advantage of uniformity in temperature, elimination of scale, etc., and more accurate control will justify in many cases the use of such a combination furnace.

Annealing Furnaces.

Of the annealing furnaces in the steel industry, the recuperative car type will have perhaps the widest application. Two furnaces of this type are now under construction. The largest of these will have a capacity of 150 tons per day when annealing at 1200° F. and is adapted for the annealing of cold-rolled strip and sheets. The second furnace, though having approximately the same dimensions, will be for annealing alloy steel bars, which require a long soaking time at maximum temperature.

The first of these furnaces is shown in Fig. 3. One notable feature of these furnaces is that the annealing will be done without the usual covers required in fuel-fired furnaces ordinarily used for this work, which will constitute one of the greatest savings in annealing, as compared with present methods. This recuperative type furnace lends itself to the highest

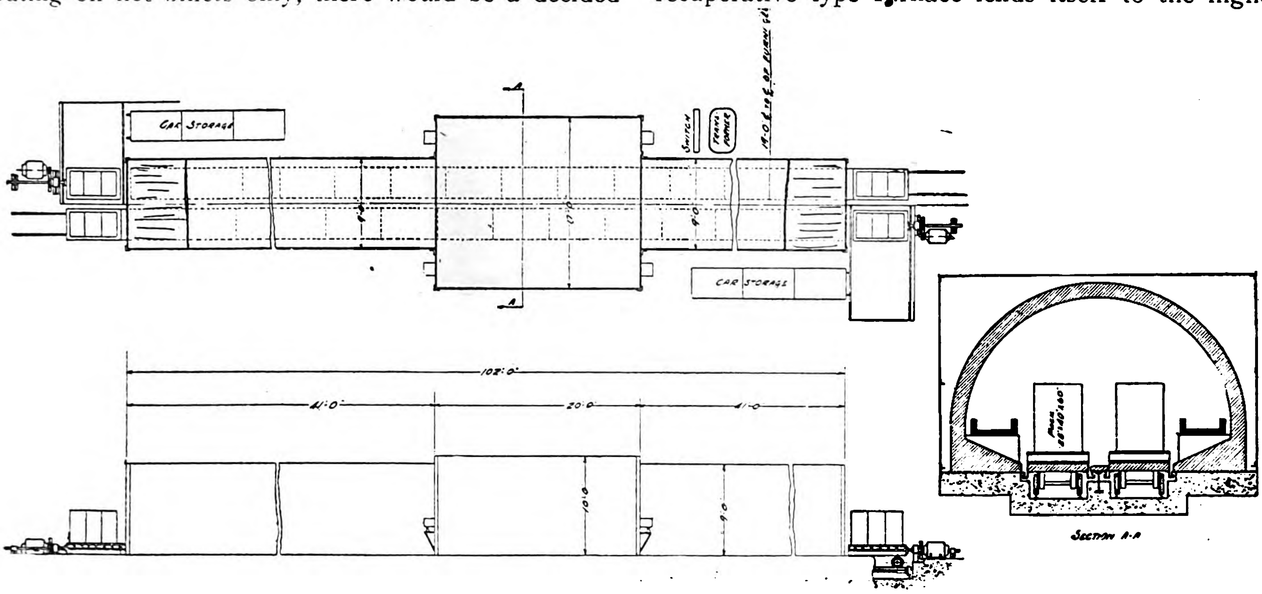

Fig. 3.—Continuous Recuperative Cary Type Furnace for Annealing Tin Plate, Cold-rolled Steel, Etc.

economy, as after the steel has reached the full temperature and is passing toward the discharge end of the furnace, a large part of this heat is given up to the cold incoming material.

In the preliminary trials of the first of these furnaces, excellent annealing results were obtained as well as high economy, but difficulty was experienced with the equipment from the standpoint of complete elimination of oxidation, due to a lack of proper precaution at the ends of the furnace. This matter, however, is one readily overcome and this equipment will soon be in regular operation.

The equipment illustrated in Fig. 3 is of 600 kw. electrical capacity and is approximately 225 ft. long by 22 ft. wide. The material is handled on sand-sealed cars, each car being substantially 13 ft. long by 4 ft. wide and adapted to hold 20 tons of material, there being in all 17 cars located on each of the two lines of track passing through the furnace, each line of cars passing in opposite directions. In the middle of the furnace is located the heating chamber proper, which is 26 ft. long, holding two cars in the heating zone on each track at a time or substantially 80 tons of material at a time in the heating chamber.

A movement of the cars takes place on each track approximately every 6 hours, discharging at that time two 20-ton cars of material, one at each end of the furnace, and similarly charging at each end of the furnace a car of cold material. The cars are moved forward by means of a hydraulic machine, operated by a 600-lb. water pressure system.

One of the requirements of this equipment is that when annealing low-carbon cold-rolled strip, the hardness should not exceed 20 sceleroscope measurement. All of the tests taken were between 18 and 19.

While no tests for maximum capacity could be taken at the time owing to sufficient steel not being available, the operation at half capacity was well within 200 kw-hr. per ton, which clearly indicated that when operating at full capacity the current consumption would be somewhat under 120 kw-hr. per ton.

Taking again large steel mill practice of current at ½ cent per kilowatt, the cost of annealing in this type of furnace would not exceed 60 cents per ton, which will compare favorably with coal-fired annealing furnaces from a fuel standpoint, and in addition will completely eliminate the expense of covers, as well as a considerable amount of labor, and will introduce a precision in annealing which it is not possible to obtain with present equipment.

The other equipment of this character, although of approximately the same dimensions, excepting being somewhat shorter in length, requires a larger heating chamber proper, even though the rated capacity is only 75 tons per day. This is due to the fact that the metallurgical requirements are such on the alloy steel to be treated that the material must be soaked for 40 hours at a maximum temperature of 1400° F.

The furnace itself is supplied with 800 kw. transformer capacity and will operate with a current consumption something under 250 kw-hr. per ton of metal annealed. In this furnace ten 15-ft. cars, each holding 30 tons of material, are located on each of the two tracks, and a maximum of 600 tons of material is in the furnace at a time, 120 tons of which are in the heating zone proper. The full movement of each line of cars will take place substantially every 20 hours, delivering substantially 72 tons per day.

One of the special requirements of this furnace is that the cooling from maximum temperature over the first 200° of the cooling range must not take place at a greater rapidity than 10° per hour. This necessitates the introduction of a very powerful and slow pulling mechanism wherein the speed of travel does not exceed 9 in. per hour.

This special equipment consists of a motor-operated chain haul similar to the equipment used in the larger types of draw benches for tube drawing, and is supplied with a 10-hp. motor through seven gear reductions. As the cars must pass through a sealed entrance hood or chamber before going into the furnace proper, this precaution being found necessary in order to prevent reducing the atmosphere of the furnace during charging, the pushing mechanism and the door operating mechanism are interlocked so that when the push button starter is operated the interlocking mechanism first raises the door of the entrance hood, then the cold car of material is pushed into the chamber, the entrance door closed, the door to the main furnace next opened, the pusher continuing the push of the car just far enough into the entrance hood until it comes in contact with the main line of cars in the furnace. From this point on the travel is at the rate previously mentioned, namely 9 in. per hour, during which time the door at the discharge end of the same line of cars at the opposite end of the

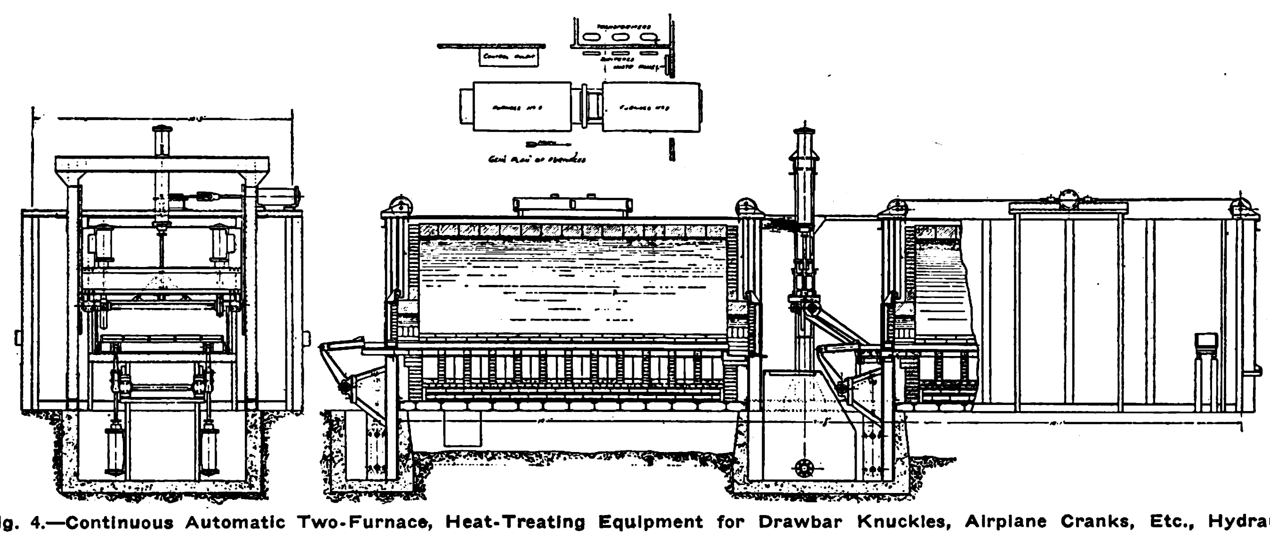

Fig. 4.—Continuous Automatic Two-Furnace, Heat-Treating Equipment for Drawbar Knuckles, Airplane Cranks, Etc., Hydraulically Operated.

furnace is opened and the car at the discharge end moved into the cooling hood at that end, the discharge door on the vestibule itself still being closed. When the cold car being pulled in has come fully within the door line of the furnace proper, the door is dropped behind it and the heating chamber thus sealed.

At this point, the pushing dog behind the car is reversed and it is returned to its starting position to bring another car into the entrance hood. While doing so, however, a pull-out chain, operated by the same shaft as the main pulling drum, latches, through means of a special dog, into the car of cooled material on the opposite track, moving it a few inches forward from the line of cars that has pushed it to the discharge position, then the interlocking mechanism drops the door in front of the line of cars, after which the outer door of the vestibule is opened and the drawback mechanism pulls the car entirely clear of the furnace, at which time the door of the vestibule is closed. Immediately following this operation a similar operation to the one just described begins at the opposite end of the furnace, the chamber and the furnace proper being first opened.

Heat Treating Equipments.

It is, however, in heat treating equipments—which consist of two furnaces, one for the hardening temperature and one for the drawing temperature, in connection with a quenching mechanism located between—that electric furnaces have been first recognized as standard equipment for exacting work in the steel industry, and the earlier of these furnaces, especially of the automatic type, have been in use now for several years.

One of the most notable of these is an installation made at Sharon, Pa., over four years ago which the following year was augmented by a duplicate installation.

A similar equipment of the same capacity was installed last year for the heat treatment of crank shafts for the 12-cylinder Liberty airplane motor. This equipment is shown in Fig. 4. On account of the irregular shape of the material under treatment and also to enable other sizes and types of airplane shafts to be handled interchangeably, a special type of cast steel chair was developed so that the direct force of the pushers brought against a line of these chairs, the material to be heated thus lying independent and free from strain while going through the furnace.

The steel used in these crank shafts was perhaps one of the most difficult to heat treat, and the requirements were most exacting. Opportunity for obtaining the exactness of this treatment was in this case readily available, as test pieces were taken from each end of every piece, and it is interesting to note in connection with this rigid inspection that for days at a time, when producing even several hundred cranks a day, there would not be a single rejection for any cause. This fact not only speaks well for the heat treating equipment but for all the previous operations in connection with the steel, including the forging, heating for forging and the making of the steel itself.

Anchor Chain Heat Treating Furnaces.

A heat treating equipment of similar capacity but with a modification as to handling mechanism is installed at the plant of the National Malleable Castings Co., Cleveland, Ohio, for the heat treatment of cast steel anchor chain. This consists of a 600-kw. hardening furnace, approximately 28 ft. long by 16 ft. wide, and a hearth the full length of the furnace and 6 ft. 6 in. wide. At the discharge end of this furnace is located a concrete quenching tank, 40 ft. long by 8 ft. wide, for quenching the chain. At the other end of this pit is a furnace of similar size but of 300-kw. capacity for drawing the temperature of the chain after quenching. Each of these equipments has a rated capacity of 50 tons of chain per day and the current consumption when operating at capacity is substantially 450 kw-hr. per ton, this current consumption being 150 kw-hr. per ton higher than in the other heat treating furnace just described and than the two similar sets at the same company's Sharon plant, due to the fact that the material is such that a larger furnace chamber was required for a given capacity. (Fig. 5.)

The charge of material consists of two 90-ft. lengths of 2-in. cast steel anchor chain, folded into loops 22 ft. long. These loops are dropped over heavy cast steel hooks, the ends of which, when the charge is in the furnace, protrude through recesses cut in the furnace door. The ends of these hooks are connected to a heavy steel cross bar, which is provided with lugs for fastening on the pulling chains, operated by a heavy winch, similar to a crane drum and equipped with a 20-hp. motor. One of these winches is located 30 ft. beyond the discharge end of the drawing furnace, the other directly over the quenching pit.

The operation of heat treating these chains begins

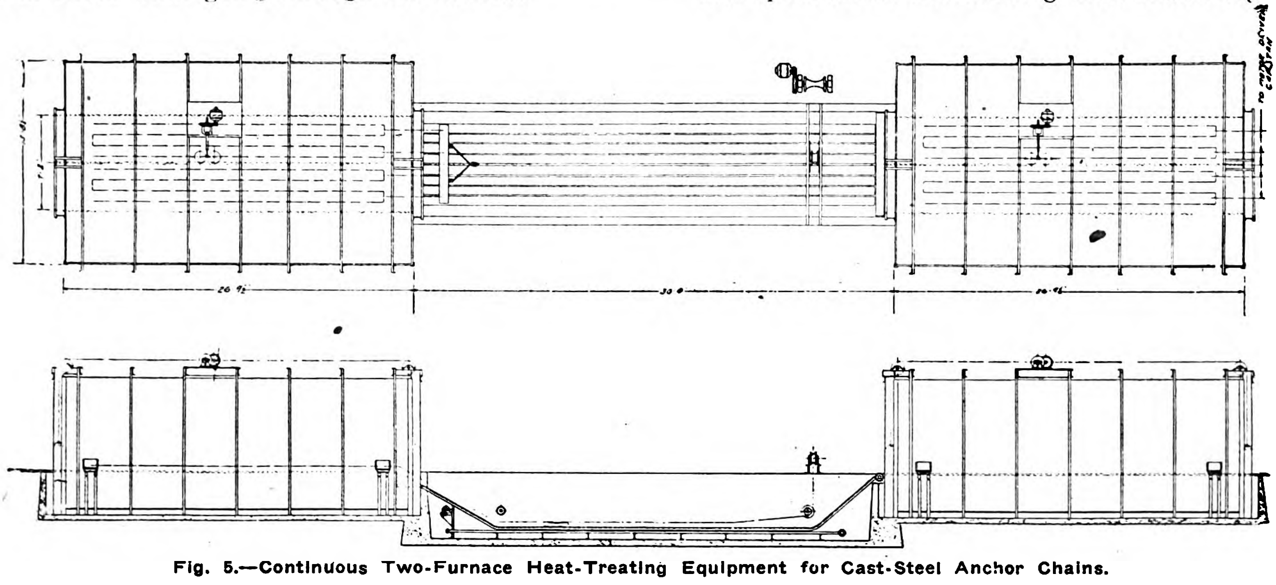

Fig. 5.—Continuous Two-Furnace Heat-Treating Equipment for Cast-Steel Anchor Chains.

by dropping the loops of the folded chain over the hooks in front of the charging end of the hardening furnace, the hearth of the furnace being level with the foundry floor. The pulling chains are dragged through the hardening furnace from the front end by means of a light iron bar, the winding drum backing off the chain as it is pulled through. These chains are now hooked onto the steel cross bar of the cast steel hooks just mentioned, the winch reversed and the chain pulled into the hardening furnace, where it remains for substantially 2 hours, during which time it is fully and entirely heated to the furnace temperature, which is about 1650° F. The doors of the hardening furnace are then opened and the winch pulls the chain out of the furnace into the quenching pit, where it lies on a steel framework composed of 7-in. channels. As the chain is immersed into the quench it is met by a strong flow of fresh water from submerged nozzles so as to give it an initial chilling, directly as it is immersed. As the tail ends of these chains pass out of the furnace door, the door closes and the chain is allowed to lie in the quench for several minutes. Before it is completely cooled, however, the chains from the winch of the second furnace are dragged through that furnace and hooked into the cross member and hooks holding the chain in the quench. The pulling chains from the first furnace are disconnected, the doors of the second furnace are opened and the winch of the second furnace pulls the chain into the drawing furnace, where it remains for another two hours and is subsequently and in a similar manner withdrawn from that furnace.

Large heat treating furnaces of the automatic type such as are described in this paper, whose certainty of operation and precision of treatment have been clearly observed over several years, justify the consideration of the heat treatment of large tonnages of heavy material. such as steel rails. The building of equipments for such purposes presents no serious difficulty.

It is readily apparent to anyone interested in this subject that the heat treatment of rails is highly desirable, as the increased physical properties readily obtainable by a proper heat treatment are such as to very remarkably increase their efficiency, not only adding to the life fom the standpoint of wear, but adding materially to the ultimate strength and the elastic limit, without appreciably sacrificing the ductility or toughness, and the only real question that can be raised is whether successful heat treating equipments can be found wherein every rail treated will have exactly the heat treatment specified, and whether such equipment can be rugged enough to operate with precision over long periods of time, and the cost of operation come within a reasonable commercial range.

The furnaces described in this paper, especially those of the automatic type, which have records of years of successful service, fully answer the question as to precision and reliability.

As to the special requirements of an equipment for the handling of rails, this will require, of course, a rugged quenching mechanism that will prevent a 33-ft. rail section from twisting during the quenching and perhaps a similar mechanism after the drawing operation.

Such an equipment will have the advantage of complete elimination of the gag press operation now admitted to be one of the principal undesirable operations in the making of steel rails.

As to the commercial cost of the heat treating operation, as compared with the increased physical properties, it may be stated that the actual cost for electric heat under the conditions named in this paper would not exceed $1.50 per ton, and the labor cost would probably be no more, and perhaps less, than is now required in the straightening press operation above referred to. The ultimate strength of the rail would in all probability be increased more than 25% and the elastic limit perhaps doubled, while the life of the rail from a wearing standpoint would undoubtedly be materially increased. It is a conservative statement to say that a 25 to 50% more effective rail from a wear and safety standpoint could thus be obtained at an additional cost per ton of not to exceed 5%.

The equipments described in the latter part of this paper are the forerunners of electric furnaces of the type that will soon come into regular use for operations on a far larger scale than will generally be conceded by the average steelmaker today and will embrace the wide and almost exclusive use of certain types, such as the soaking pit and certain forms of the re-heating furnace first mentioned in this paper. While in some cases there will be an actual reduction in cost of operation over present methods due to the electric furnace, even for steel of average quality, the more rigid requirements in finished product will in some cases compel the use of electric furnaces.

Where requirements of the steel specified must be met, a lower cost may readily be found in operating electric furnaces, when taking into consideration the difference between the cost per ton of material put through the furnace, as compared with the cost per ton of material meeting the specifications.

Many of the arguments used against the introduction of electric furnaces were used against the introduction of large motors in the steel mills and against electric haulage, and the statements frequently made through all the years about any innovation that "it has not been done and it cannot be done" must gradually yield, as one by one the various types of electric furnaces from heat treating equipments to soaking pits go into regular, commercial service.

ELECTRICALLY HEATED STEAM BOILERS.

Under certain special circumstances the electrical heating of boilers is justifiable; for instance, in very northerly countries, for the wood pulp and paper factories with water-power driven machinery, which requires large quantities of steam for the process.

The Allegemeine Elektricitäts Gesellschaft of Berlin, Germany, has developed special boilers in which the heating is effected by the passage of electric currents through the water. For this purpose narrow tubes of insulating material are provided. These contain water and are vertically arranged so as to communicate with the interior of the boiler at the upper and lower ends of the tubes. Current is sent through the water columns contained in the tubes and, as the resistance is great, considerable voltages are required. Alternating current must be used, in the case of three-phase currents the tubes are connected in groups of three. The current is regulated by moving the electrodes in the tubes. The efficiency of the boilers is 95% and over, and one kw-hr. of electricity produces about 2.75 lb. of steam at 90 to 120 lb. pressure. Up to the present electric steam boilers have been built in units up to a capacity of 1500 kw. with voltages of supply up to 10,000 volts.

Service Tests of Small-Capacity Meters

Schedules of Tests—Experiences as to Errors—Paper Before Ohio Electric Light Association

By ARTHUR HORACE BRYANT
Meter Engineer, Cleveland Electric Illuminating Co.

FIVE years ago our business, like that of many other industries, was getting along very satisfactorily on the whole. To be sure, there was always a changing condition to be foreseen, and there was the ever present problem of labor and its various moods, its restlessness and consequent "turn over" with the continual question of how best to select and keep efficient workers—for hereupon rests the success of any enterprise. However, the aims and purposes of our lives and business were being worked out without any very serious obstacles or challenges, when suddenly and before we could realize what it all meant, we were confronted with the world at war. First, we assured ourselves that we were safe and could go about business with little or no interference. But soon we too had cast aside as non-essential everything that was not contributing in some measure toward the winning of the war and we entered into the spirit of the day. Men all about us—employes of experience and those who could ill be spared—left to others their responsibilities and set out to help in the larger work of the country. Help became scarce, wages and material commenced to climb in price; you know full well how the central stations were ofttimes taxed to their limits to meet the increased demand for more power; their business boomed. However, the added work had to be accomplished by fewer men at a greater cost and this was capped with an increased scarcity and poorer quality of coal, not to mention other needful supplies. The rates having been fixed and contracts for most services having been given on a peace-time basis, and with no upward revision possible except at the approval of the Public Commission—representing a public already exasperated with uncontrollable advances of almost everything needful to life—and with a money market tight, the central stations found themselves in anything but an enviable position. Nevertheless, the war had to be won no matter to what extent the sacrifice, and the central stations were an important element in the industrial performance of this task. All non-essentials had to be cut out or deferred; even many things that previously had been looked upon as essential had to be set aside for the time. Periodic testing of meters was one thing that could thus be deferred and the labor and expense thereby relieved could be used to fill in the dangerously yawning gap in departments with more imperative needs.

All periodic testing, however, could not be deferred without more or less irreparable losses in revenue. In the case of the residence class meter, however we have not only the largest percentage of the total number of meters, involving a large share of the cost of maintenance, but therefrom is derived the smaller percentage of the total revenue. Consequently, in practically every large central station the periodic testing of residence or smaller capacity induction meters has been partially or entirely discontinued for the period of the war, with exception of such necessary tests as are required by complaint investigations or on account of verification of questionable registrations at the request of the billing or accounting departments.

Now that the armistice has been signed and war activities are rapidly declining, we are fast approaching or have already arrived at the time when we must again pick up the work which was temporarily deferred. However, we have in the meantime come to look upon many things in a new light and from a broader experience, so that we are asking ourselves and one another: What changes should be inaugurated and what improvements are possible? We do not wish to return to the pre-war methods and conditions except insofar as such shall be found to be the best and most satisfactory.

Since we are finding meters with extended periods between periodic tests still registering their loads within their required limits, such questions as these naturally confront us: How much longer could these service periods between periodic tests be extended without the occurrence of serious errors? What should we try to establish as the most suitable period between tests?

If such a period can be safely extended one or two years, say, from three years to four, or even five years, it would decrease the costs of such tests from 35 to 40%. Assuming for the moment that this saving thus made should be but half this amount, it represents an economy well worth the consideration of every central-station company.

One large central station to our knowledge has at the present time over double the number of meters in service to that of five years ago. In contrast with this, the total number of meters tested this past year was less than 40% of the number tested five years ago. Even if, with the return of peace conditions, this company were to receive back all the testers it has lost—which cannot be expected—it would fall far short of what would be required to maintain its pre war schedule of tests. It takes time to secure and properly train men to the point where they are capable of handling satisfactorily the tests on customer's premises. What should we recommend to this company and others similarly situated when they come to us for advice?

Should we recommend extending the intervals between tests of the smaller capacity induction meters to—shall we say five years or what?

Should we include in this recommendation all modern makes and types of induction meters or ought we to qualify this in certain cases?

Should we recommend that an inspection with an approximate load test be made after, say, 60 to 75% of this period has elapsed?

Should we recommend a careful consideration of all meters in this classification which show a questionable deviation from the normal monthly registration to be followed up with a test if a satisfactory explanation is not readily obtained therefor?

Should we advise the changing of meters within this class for laboratory or shop tests where the operating company shall find itself incapable of making service tests after an elapse of, shall we say ...... years? Is this latter method going to prove acceptable to the company or customer as representing the service accuracy of such a meter?

Should we strive to maintain the small capacity induction meters within the same limit of accuracy as those involving larger revenues? If not, what should be the limit? Note: The cost per test differs but little between the meter with a monthly average revenue of but $2 to $3 from that which runs into hundreds of dollars a month. A 5% error in the first case represents a loss in revenue very much less than 1% in the latter.

Do some makes and types of meters have causes of error different from those of other makes and types? If so, would it not be advisable to establish the interval of service between period tests, taking also into account the type and capacity of the meters involved, rather than to base the same on the meter capacity only, irrespective of type Should the average cost of test and the approximate average yearly revenue have any influence in the establishment of the service period between periodic tests? If so, how should the same be applied?

With such questions as these in mind, the writer desiring to ascertain what might be the status of some of the larger central stations in respect to some of these matters, prepared a simple questionnaire which he sent to 12 meter superintendents in various parts of the country. Nine replies were received which, together with the writer's, makes ten. Following is an attempt to summarize their questions and answers:

(1) Regarding the normal pre-war intervals between periodic tests in the case of the smaller capacity induction meters: Two reported that they had been following a 24-month schedule. One reported that they had been following a 30-month schedule. Six reported they followed a 36-month schedule.

(2) The question was asked as to why these particular schedules were adopted rather than some other. The answers were quite varied in nature. Two attempted no answers at all; one, who reported a 24-month schedule for small a. c. meters, replied that when the schedule was adopted there were several new types of meters being placed in service, and they were somewhat apprehensive of their performance over a long period of time, so they felt that a test at least every two years was warranted from the point of being assured that they were properly maintaining the meter accuracy. Another states that their schedule (a 36-month) was adopted because a great many other companies had adopted this same time interval for small capacity residence type a. c. meters. Two laid the burden upon the State Commission, claiming that the schedule for residential meters was adopted by their Public Utility Commission, "probably after comparison with other commission rules and investigation regarding the performance of meters." Still others reported that in the case of a. c. meters the schedule was not originally established on any definite basis so far as the accuracy of the meter is concerned but it was started on the theory that all meters should be tested once a year, but this was soon found to be unnecessarily often, due to the large number of O. K. tests; so that this schedule was accordingly lengthened as far as it was thought to be safe considering the accuracy obtained and revenue derived from these meters.

(3) Answers to the question whether it had been possible to maintain these schedules uninterruptedly up to the first of this year shows that in the case of each of the ten reported, none had been able to maintain such schedules, while at least four stated that they had practically abandoned for the time being all periodic testing of residence meters, one adding that "the Billing Department kept a pretty strict watch over the monthly bills for the small customers, and when the bills showed any abnormal fluctuation from either the previous month or the corresponding month of the previous year, they made a special investigation, and in case they were unable to discover anything which satisfactorily accounted for some fluctuation, they tested the meter."

(4) As to the intention to return to the pre-war schedules of testing residence meters, four replied to the effect that such was their intention. One replied that they contemplated trying to have their schedule for small capacity induction meters changed from 30 and 36 months, giving as their reason that they thought these meters would give good results on the longer schedule. Three replied that they did not contemplate returning to their pre-war schedule. It is the opinion of the writer that these latter were not so required by their State Commissions while the others were.

(5) With a view of ascertaining if there might be any approximate relation between the error occurring in a meter and the million of turns of the moving element, the question was asked: "Have you any data showing the relation between shaft turn of the moving element and the relative accuracy of the meter registration?" Seven answered that they had no data on this subject. One sent curves made up which showed that when but a few meters were considered, the relation seemed to be rather erratic.

I would like to quote from the reply of one who has evidently given this matter considerable thought and study, in which he writes: "It is rather difficult to obtain any definite relation between shaft turns of the moving element and the relative accuracy of registration. With sapphire jewels, the jewel has a very considerable influence on the accuracy of the meter but the curve of deterioration is not a straight line. We found that our accuracy was very much improved by arbitrarily removing sapphire jewels at each periodic test and having them repolished, and our schedule was made, as before mentioned, largely upon the expected life of the jewel." (The reference thus referred to is: "The d. c. schedule was based originally on the basis of revolution of the disc, as at that time we were using sapphire jewels which had a considerable influence on the sustained accuracy of the meter. We are now using diamond jewels but are still retaining the 12 months' limit of these meters and unless the use is very light, I do not believe it wise to lengthen it.")

Continuing, he adds: "It made considerable difference in the wear of the jewel, whether the meter was running at high speed or at a comparatively low rate With diamond jewels the deterioration is practically all in the shaft end, and compared with the other sources of trouble, is practically negligible. From the data I have compiled on the C. S. type of meter, the deterioration in accuracy seems to be a function of the time the meter is in service, or rather the time between periodic tests rather than a function of revolution; but the rate of change is not sufficiently uniform in the meters so far tabulated to allow us to base our test accurately even on this factor. With the a. c. meter, from the little data we have compiled to date, there does not appear to be any relation whatever in actual practice between the sustained accuracy and the length of time between periodic tests. In other words, the average accuracy of a block of meters allowed to run 48 months appears to be practically the same as that of a similar block of meters allowed to run 12 to 24 months. We are compiling data of this, but as yet have not enough available to make showing conclusive."

The writer has been compiling data covering several hundred meters grouped according to make and type. His data bears out the conclusion expressed in the above to the effect that it thus far affords little upon which to help establish an efficient interval between periodic tests. Probably the most striking conclusion to be reached from this compilation is that no period was reached which showed a decided tendency for deterioration of accuracy. Possibly when the tests cover longer intervals between tests, this characteristic may appear.

(6) The last question in the questionnaire, previously referred to, aimed to bring out, if possible, some relation between the average cost of testing and the average revenue derived from any class of meters, it read: "Do you consider it practical to try to establish the test period by taking into consideration the average cost of test and the approximate value of revenue saved through corrected accuracy" In answer to this, the party previously quoted writes: "In spite of what I have said in the foregoing, I think that for d. c. meters approximate curves of increasing errors could be had that would give some indication of the errors to be expected under certain conditions and that it would be possible to apply these curves, taking into consideration the average cost of test and the approximate value of revenue involved through correction of accuracy, to make it worth while. It would be considerably more complicated than our present method of arriving at test periods. For meters that are outside of what would be commonly known as small use meters we have used for years a method which roughly approximates this idea, but in addition meters which show a decided tendency to fall off in accuracy, due to either its location or to the use to which it is put, the period is shortened. One complication with a. c. meters is, of course, the weakening of the magnet which can hardly be allowed for." Another answer reads: "From our data I do not believe it is practical for us to test meters on the basis of shaft revolutions. There is one weakness I see in this method. Most full load errors are due to change in magnet strength due to aging or short circuits. This has no bearing on shaft revolution." This has been brought forcibly to my attention on the test we are now making of meters which we had extended to the four-year plan." Still another writes: "We feel as though satisfactory results can be obtained by arranging a test schedule primarily based on the capacity of meter." Contrasted from this, showing considerable diversity of opinion expressed, another writes: "The average cost per test and the approximate revenue saved to correct its accuracy should be considered in making up a test schedule, but consideration should also be given to maintaining meter accuracy. By this I mean that I consider it good policy to set a time interval whereby we test the meter before the revenue commences to decrease because of slow meter, then to set a time interval whereby we are almost certain to find meter running slow."

The general conclusion gathered from these very interesting replies are as follows:

(1) The pre-war schedule for periodic tests of the smaller capacity induction meters was in most cases 36 months. No longer periods have been indicated.

(2) A few, if any, of the larger central stations were able to maintain this schedule for this class of meters during the war. A number of companies practically abandoned periodic tests on meters of this class during the war time conditions.

(3-4) Those companies operating under State Commissions, which have adopted definite ruling pertaining to the testing of meters of this class, are endeavoring to return as rapidly as possible to their former schedule of tests.

Those companies operating under more liberal ruling are not contemplating, for the present at least, the return of their pre-war schedule for this class of meter. The reason for this change seems to be based on the opinion that tests made after extended periods show no increased tendency to error over those taken after the previously shorter periods.

(5-6) Little or no effort appears to have been made to arrive at a period between periodic tests for meters of smaller capacity from an analytical, systematic or economical basis.

After considering the problem of extended intervals between periodic tests, I would like to present the following suggestions for your consideration:

Since the general accepted period between periodic tests on the residence class a. c. meters is given as 36 months and since it is the expressed opinion of not a few that this period can be safely extended by one or two years, I accordingly would recommend:

(1) That a thorough inspection be made in place of usual 36-month test and that where the inspection raises no question as to the accuracy of any given meter, its test be set at 60 months (24 months after the inspection).

(2) The adoption of the following, where it is not already the established policy, to the effect that all cases of unusual changes in monthly registration be investigated and where there shall be no satisfactory explanation therefor, that a thorough inspection or test be made at once.

(3) That the inspections above referred to (Sec. 2) should cover:

(a) General external conditions, such as condition of wiring, seals, etc.

(b) Approximate stop-watch or whatever standard check of the meter on a standardized 60-watt load.

(c) Where this check shall show the meter accuracy to be within 4%, the meter may be opened, the jewel cleaned and oiled or replaced when rough. The top bearings of such meters as show characteristic friction at this point may be cleaned and oiled, the magnets and disc cleared from any foreign matter.

(d) The meter to be again sealed, daily reading recorded.

(e) Where the 60-watt test shows the meter to be found in error over 4 or 5%, the meter should be again checked on this load after general inspection and cleaning. If it still is shown to be over 4% in error, the meter should be scheduled for test.

(f) Normally the last feature of this inspection should be a 10-watt or starting load taken to insure that the meter has no serious light load error.

CHAIN TRANSMISSION IN NEVADA MILL.

Eight Tube Mills and Several Auxiliary Machines Electrically Driven Through Chains in Ore Mill.

Mining and metallurgical companies in the Pacific coast and inter-mountain states were among the first of industrial concerns to adopt electric drive with silent-chain transmission for the operation of power and milling equipment.

While the problems of transmitting power are practically the same in all the industries, the data and illustration given herein show the special adaptability of that type of transmission to the driving of tube mills, conveyors and centrifugal pumps in ore-reduction plants. They relate especially to the equipment in the plant of Tonopah-Belmont Development Co., Tonopah, Nev., in which gold and silver ores are pulverized to a very fine state preparatory to treatment by the cyanide and flotation processes. This mill contains eight Allis-Chalmers tube mills, each 5 ft. by 18 ft., and driven at a speed of 30 r.p.m.

The tube mills are operated in four different units, each unit of two mills being driven by a 100-hp. motor running at 570 r.p.m., with Morse silent chains for transmitting the power. Two chain drives are required for each tube-mill unit. One of these connects the motor to a countershaft, while the other connects the two countershafts together. Each mill is controlled through a friction clutch coupling, making it possible for the two mills to be operated singly, or both at the same time. The arrangement of a tube-mill unit, with motor and silent-chain connections, is well shown in the illustration at the bottom of the page.

A summarization of the Morse silent-chain installations in this mill is as follows:

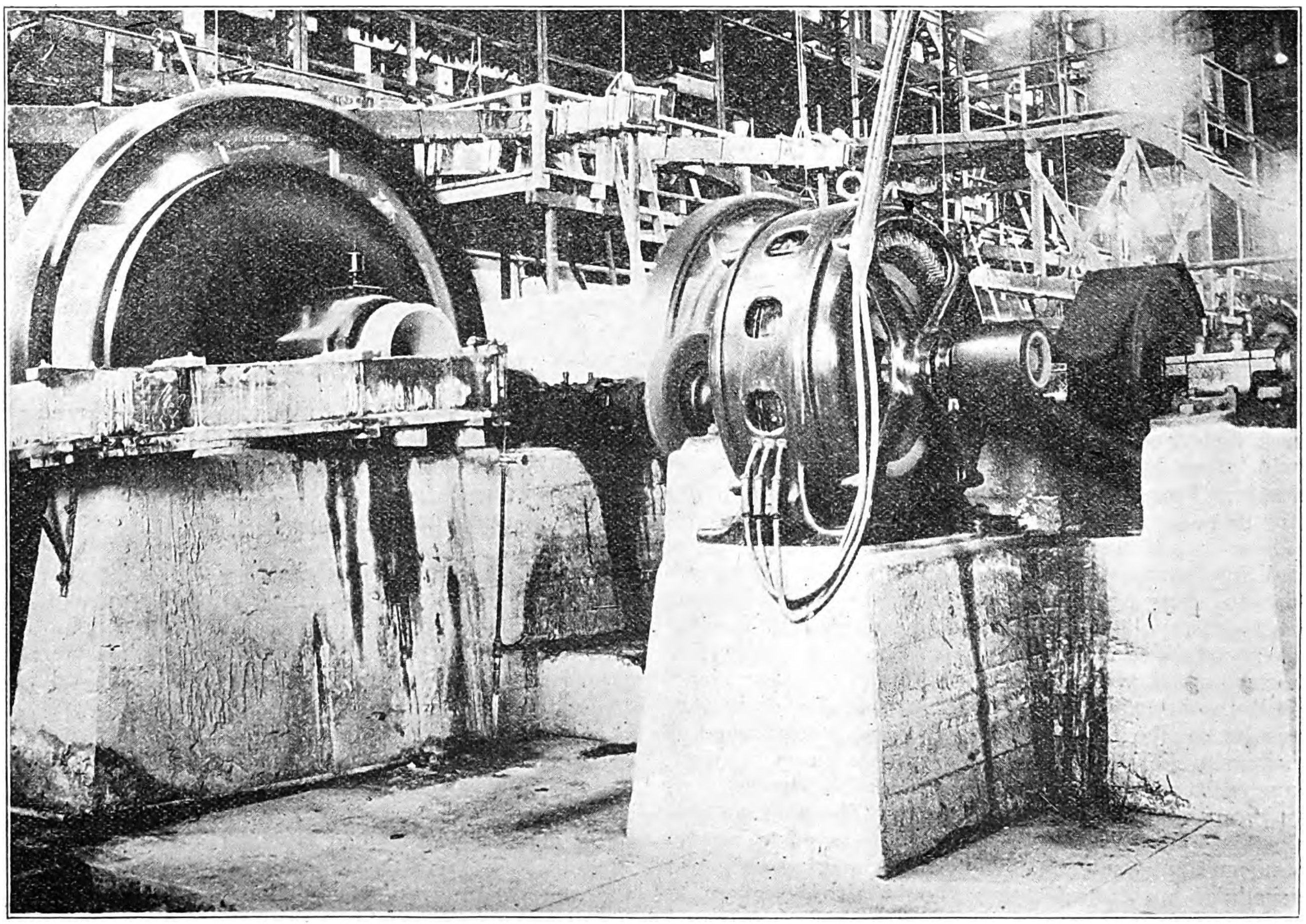
Four 100-hp. drives, 570-162 r.p.m., 48-in. centers, each made up of one 19-tooth driving sprocket, 9.06-in. diameter; one 67-tooth driven sprocket, 32.26-in. diameter, and one chain 13.75 ft. long, 10 in. wide, and 1½-in. pitch. Also four 100-hp. drives, operating at speed of 162-162 r.p.m., 40-in. centers, each having one 53-tooth driving sprocket, 34.13-in. diameter, and a driven sprocket of 53 teeth and same diameter; the chain in each drive being 15.67 ft. long, 6 in. wide, and 2-in. pitch.

There are other motor drives in this mill for which silent-chain transmission is employed. One of these consists of a 15-hp. drive, 860-113 r.p.m., 56-in. centers, with a 4.87-in., 17-tooth driving sprocket; and a 37.14-in., 129-tooth driven sprocket; one chain 15.3 ft. long, 3 in. wide, and 9/10-in. pitch. This is for operating a conveyor.

Another 15-hp. motor drive, with silent-chain belt connecting with a Krogh centrifugal pump, has a speed of 1150-1000 r.p.m., requiring a 6.29-in., 31-tooth driving sprocket, and a 7.09 in., 35-tooth driven sprocket, on which operates a chain 4.8 ft. long, 4 in. wide, and ⅝-in. pitch.

While this type of chain drive is positive, there is sufficient flexibility to relieve the motor and the driven machines from vibration; and the sustained efficiency is understood to reach 98.6% or higher.

The installations described were made in 1912, and this is one of the most complete milling plants in Nevada.



View of Tube-Mill Unit in Mill of Tonopah-Belmont Development Co., Showing 100-Hp. Motor Drive, With Morse Chain Transmission.

Editorial Comment

Parallel Sessions at Contractor-Dealer Conventions

ONE of the most interesting and instructive sessions at the recent annual convention of the National Association of Electrical Contractors and Dealers was that of the Repair and Sale of Used Apparatus Section. Although this was the first time that any attempt had been made to provide for the discussion of this important subject, the interest displayed by those who attended the meeting assures that in the future this subject will be given a prominent place in the convention programs.

The subject is one that is closely allied with electrical contracting and merchandising, inasmuch as it is usually carried on in conjunction with these, yet it differs from them in many respects. For this reason it is surely advisable to hold separate sessions for its discussion. However, there is a question as to the advisability of holding parallel sessions for this purpose for many of the members desire to attend all the sessions as their business comprises all three lines.

While it is true that parallel sessions are held at the conventions of the National Electric Light Association and other organizations and that a considerable saving in time is effected in this way, the conditions are different from those that exist at the contractor-dealers' conventions. At the N. E. L. A. conventions the majority of companies send several representatives each one to cover a certain section. The smaller members of the contractor-dealers' association especially are not in a position to send more than one representative, at present anyway, and this representative is usually the owner. For this reason it is very desirable that the sessions be arranged so that they will not conflict, especially those dealing with merchandising, contracting or repair work. But, in any event the sessions of the latter should continue for they will undoubtedly prove of great value, not only to the members engaged in such work but to the association as a whole.

Test Schedules for Residence Meters

WITH most central-station companies, the residence customer represents the largest number of customers and the ones that bring in individually the smallest revenue. Under these circumstances it is imperative that those costs that are independent of the amount of energy consumed should be kept to a minimum. These charges include the investment in meter and service connections, the cost of maintaining and reading meters, cost of billing, etc.

Routine testing of meters registering the residential consumption is important because, except for the fixed charge often levied to take care of fixed charges upon apparatus, it is the meter reading that determines the revenue from this type of load. The residence load is a comparatively small one, individually, and exists on the average for but relatively short periods each day. Accurate registration is therefore very important. Testing the residence meter, while not costly, perhaps often approaches and sometimes exceeds the revenue derived from a single month, and for this reason it is most advisable to have a maximum lapse of time between routine tests compatible with accuracy of meter operation.

Just what period may be safely allowed between routine tests is a mooted question. Some companies allow 24, some 30 and some 36 months to elapse between tests. The labor situation created by the war necessitated revising meter testing schedules, not from choice but from necessity. Companies are now finding that it may be quite permissible to decrease the frequency of testing from 36 months to some longer period. Sixty months has been proposed. If this can be done quite generally without loss of revenue to the central station or unfairness to the customer, there is a very real gain to the former in that a financial saving accrues as well as other complications.

Elsewhere in these columns will be found an account of what some of the Ohio utilities are doing in the way of making periodic tests of residence meters. Modifications in the test schedules are proposed by which this item of cost can be very materially reduced. This article is worthy of consideration by every central-station company since every such company is dependent upon its metering devices. It is hoped this matter will be taken up alike nationally and that it will be found that much less frequent testing of residence meters is usually permissible.

Electrical Heat Treatment in the Steel Industry

ELECTRICITY in the steel industry. But, then, the steel industry without electricity would be very much like the steel industry without iron. Mention the steel industry and one instinctively thinks of electricity—electricity for driving the rolls and tables, electricity for running the cranes and hoists and supplying the light.

The steel industry is the largest single industrial consumer of electrical energy. Yet as a consumer it may perhaps be said to be only beginning. Most of the electrical energy consumed by the steel industry is used by motor applications of divers sorts. The electric furnace is making headway and each year sees more and more electric furnaces finding their way into the steel industry, mill and foundry.

But there is another use for electricity that has as yet attracted but little attention except perhaps from those most closely interested. Just as intense heat made electrically is now being used on an ever-increasing scale for melting steel and refining purposes, so too there are those that expect heat made electrically to be employed upon a large scale in the not far-distant future for heating at the lower temperatures, for the soaking pits, for the reheating and annealing furnaces. Electricity so used would represent a very high load-factor and a very considerable consumption of energy.

Mr. Thaddeus F. Baily tells in other columns of this issue what electricity has done in heat treatment in the steel industry during the last year or two. He tells enough to show the vast possibilities of this form of load. He foretells, based upon his experience, the types of furnaces that may be expected to find the widest usage and what they will represent in the way of energy consumption and cost of operation.

It is undoubtedly only a matter of time before soaking pits, reheating and annealing furnaces or ovens come into wide usage because of the better product they make possible and the greater convenience and assurance of uniform product. Meanwhile there is a development stage to be passed through. The possibilities of electricity for these purposes must be made known and those having the greatest faith and the greatest interest at stake must be expected to spread the word. Every engineer connected in any way with the production of steel and electricity should give the above-mentioned article the study it deserves. Electricity for heating at the lower temperatures will not come into the steel industry in a day. Perhaps the day is not yet when it is best that it should come. Meanwhile the more known about this phase of electricity supply the better.

Solving a Threatened Street-Car Strike

WHAT had every indication of becoming a very serious interruption of local transportation in Chicago has been brought into a very satisfactory process of settlement by a simple act of Gov. Frank O. Lowden of Illinois. The organized car and train crews of the surface and elevated electric railways of Chicago presented demands for wage increases averaging some 77%, for reduction of working hours to 8 and for other bettered working conditions. The companies replied that even now they were hard pressed to make ends meet because of high operating costs and it would be utterly impossible to grant the new demands without going into bankruptcy, unless fares were materially raised. At first the city authorities opposed any higher fares. The only body authorized to order increased fares is the Illinois Public Utilities Commission and it showed no desire to take up this matter unless the usual procedure were followed wherein the companies would first have to show that their actual expenses were clearly beyond their income. There was, therefore, every prospect of a continued deadlock coming to a climax by the probable strike of the 14,000 employes involved and very grave interference with all business and social activities through paralysis of the most vital means of urban transportation.

Happily, at this point Governor Lowden stepped in and ordered the Public Utilities Commission to make a comprehensive investigation of the entire situation and act in accordance with its findings. This investigation is now well under way and gives every promise of being impartial, thorough and conclusive. There is a general consensus of opinion that a reasonable increase in wages is due to the men, even if it involves a moderate raise in fares, which is conceded to be an inevitable concomitant. Consequently we look forward to an early and definite settlement of the question that is fair alike to all three parties—the employes, the companies and the public.

On numerous occasions for some five years we have pointed out in these columns that the public service commissions are the bodies most fittingly adapted to consider wage or other labor disputes of the utilities that involve higher operating charges against them. Such questions should and must be considered by the commission that regulates the rates or income. A separate labor board without power to see that its findings can be carried out through abundant income is far from satisfactory, as has been shown by the extremely embarrassing financial position into which so many electric railway companies have been forced due to the wage increases ordered by the War Labor Board last summer. The utility regulating commissions represent not only the utilities and the public but the employes of the utilities as well. Each of these three elements must be fairly considered in utility wage disputes. An outside arbitration board is likely to give inadequate consideration to the public, which in the end must foot the bill.

Even if the public's interests are properly considered, there is likely to be a troublesome time lag before the recommendations of the outside board are acted on by those in authority as to rates, especially in a case like the present.

We hope, therefore, that the present Chicago case will not only be promptly, amicably and equitably settled, but that it will serve as a precedent to utility commissions in other states. This is undoubtedly the most satisfactory method of handling such cases. If legislation is necessary to enable the utility commissions to take up these matters without special request from the state executive, it should be enacted as soon as possible. Meanwhile, Governor Lowden deserves the gratitude of the entire community for having clearly seen a way that is fair to all out of a very threatening difficulty.

Current Events

Important Topics Discussed by Ohio Lighting Men—Plans for Big I. E. S. Convention — Facts on Reconstruction

PUBLIC RELATIONS, SOCIALISM AND TRANSMISSION TOPICS AT CEDAR POINT.

Closing Sessions of Ohio Electric Light Association Deal with Problems of the Hour.

The first two days of the Ohio Electric Light Association's convention at Cedar Point, O., were reported in the July 19 issue of the ELECTRICAL REVIEW. The two last days of the convention, July 17 and 18 were devoted to sessions, addresses and pleasure. On the last day the election of officers for the ensuing year took place. C. H. Howell was elected president, F. H. Golding was elected vice-president, D. L. Gaskill, Greenville, was re-elected secretary-treasurer.

On Thursday two sessions were held. In the morning Freeman T. Eagleson, Columbus, O., presented an address on "The Relation of Utility Companies to Public Service Corporations," in which was discussed the vital problems of today faced by the great public utilities. At this session was presented the report of the Illuminating Committee. This report, presented by F. C. Caldwell, reviewed the work of this committee during the past year. It also made recommendations that the giving of correspondence courses to Association members be continued; that the number of men taking this course be increased and a second series started on the completion of the first; that effort be made to extend the use of the "Technical Letters" course among contractor-dealers, architects and others.

In the afternoon F. G. R. Gordon presented an address on "The Trend of Socialism" before a very large attendance. This was a scathing indictment of the trend of socialism. Mr. Gordon told what socialism has done in Australia, New Zealand and Great Britain. He showed what it was doing in Canada and what it was going to do here unless stopped. He pointed out that municipal control was the thin edge of the wedge, that the attacks upon public utilities and taking them over, was the path of least resistance. It was this path that socialism was following. He brought home to all those present the trend of socialism, its dangers.

At the conclusion of Mr. Gordon's address a water carnival was held on the beach, a number of water sports being indulged in and prizes awarded. A banquet was held in the evening, there being present about 350 persons, after which adjournment was made to the ball room.

The eighth session, held on Friday morning, completed the convention. At this session the reports of the Transmission and Distribution and Finance Committees were presented and officers for the ensuing year elected.

The report of the Transmission and Distribution Committee consisted of a review of the past year's activities, including the papers upon "An Electric Underground Record System" by M. K. Thomen, Massillon Electric Co., "Duct and Manhole Ventilation and Cable Protection" by C. M. Rakestraw, Cleveland Electric Illuminating Co., and "Voltage Regulation of Distributing Feeders as a Means of Improving Central Station Efficiency" by Frank Hershey, General Electric Co., and "Industrial Power Substations" by G. B. Schneeberger, and a statement from the Detroit Edison Co., as to their underground high-voltage distributing system.

A general discussion followed the committee's report on high-tension transmission system design and operation. H. R. Summerhayes, of the General Electric Co., discussed the tendencies in transmission line engineering. He pointed out that much can be done toward development and improvement by closer co-operation between manufacturer and user of apparatus, since the latter is able to find out how equipment behaves in actual practice. Standardization of voltages and high-voltage apparatus was dwelt upon, the benefits being better deliveries, lower cost and interchangeability of bushings and similar details of design. A recent improvement in transformer design by which transformer taps can be changed without having access to the interior of the transformer case was explained, as were also methods of preventing moisture entering the transformer by "breathing." Mr. Summerhayes pointed out the value of the static condenser for power-factor improvement, going on to say that for capacities up to 1000-kv-a. the higher efficiency and absence of attendance, makes the static condenser preferable to the synchronous condenser, on the score of initial cost and efficiency. The influence of power-factor upon voltage regulation, and investment losses was mentioned.

The outdoor substation and outdoor apparatus came in for considerable comment as did also the automatic and semi-automatic substation and power house. According to Mr. Summerhayes, there are about 25 automatic stations in service and some 70 in various stages of completion. For those semi-automatic substations the re-closing circuit breaker was advocated, several methods of obtaining the re-closing feature being described.

W. L. Wallau briefly discussed the possibilities and problems connected with going to the higher potential of 220 kv. He referred to the paper on this subject by Silver before the A. I. E. E. convention, and also to the various reports presented before the recent N. E. L. A. convention. Prof. Caldwell spoke of certain features of re-closing circuit breakers and the control of attendantless substations. R. R. Krammes spoke of oil-break and air-break circuit breakers, drawing remarks from Mr. Summerhayes to the effect that both types of circuit breakers are answering the purpose and that to date it cannot be definitely stated just where the one switch should be replaced by the other. I. L. Kentish-Rankin spoke of the different types of commercial substations, some of which could be made entirely automatic and some where the higher investment would not be justified. For this latter type of substation the re-closing circuit breaker was particularly well adapted, reducing the time of service interruptions. A method was described by which such substations may often be made to have re-closing features without changing the type of relay, but instead merely making some cheap and simple mechanical changes.

COUNCIL OF NATIONAL DEFENSE ISSUES BOOK ON RECONSTRUCTION.

Reconstruction Research Division Prepares 188-Page Volume Giving Data on Readjustments in 46 Foreign Countries.

The following statement has been issued by Grosvenor B. Clarkson, director of the United States Council of National Defense.

Realizing that American business must, with the signing of peace, be furnished with information concerning foreign reconstruction and readjustment activities, the United States Council of National Defense has prepared for distribution the latest data available.

Through its Reconstruction Research Division, the Council is now transmitting this material in the form of a printed volume of 188 pages to all member organizations of the United States Chamber of Commerce and to all public libraries.

The volume is completely indexed and covers as fully as possible in tabloid form information gathered by the Council. An instance of the scope of the work is in the case of Japanese notes covering not only the reconstruction problem in the Mikado's empire, but also data covering an outline of Japan's development of Chinese shipping, her colonization in Brazil, Japanese monopolization of trade in China, the relations of the empire to the Siberian Railway system, and the China-Japanese secret treaties.

The volume contains information concerning readjustment and reconstruction activities in 46 foreign countries and groups of countries, relating mainly to the governmental activities in the organization and administration of readjustment and reconstruction work.

Compiled from such important official periodical publications of the various governments as were available and from private sources where official information could not be obtained, it covers several hundred different subjects of readjustment and reconstruction activity.

Among these may be mentioned the steps taken in the various countries for the restoration of forests and the revival and increase in agricultural and forestry production; the various treatments that have been accorded discharged soldiers and sailors in the way of bonuses, employment and re-education; the facilities given for their settlement in homes and on farms; investigations made in the various countries where destruction had been wrought, concerning economic conditions; the disposition and utilization of war materials; and steps taken for the changing of factories producing war material to a status of peace production. The systems of finance, banking and credit adopted in the various countries are outlined and the steps taken for the relief of food scarcity and the rehabilitation of the invaded areas are pointed out. The need for and methods used in controlling the distribution of raw materials are outlined, and the plans for the restoration of foreign trade relations and of transportation systems are discussed.

The director of the Council, in announcing the completion of this study, stated that because of the practical impossibility of supplying all business interests throughout the country with separate copies of this digest, it has been considered best to furnish the public libraries of the country with two copies each, and in addition to deliver a copy to each of the member organizations of the United States Chamber of Commerce, as well as to all trade journals—this because of restrictions in the edition due to the necessity of conserving the limited funds available to the Council under its present appropriation.

ILLUMINATING ENGINEERING SOCIETY PLANS BIG CONVENTION AT CHICAGO.

General Convention Committee Developing Numerous Features of Special Interest—Program to Emphasize Applications of Good Lighting.

Plans for the next annual convention of the Illuminating Engineering Society were further developed at the second meeting of the General Convention Committee at the office of Homer E. Niesz, chairman, Edison Building, Chicago, on July 21. The meeting was attended by several officers of the Society, including President-elect S. E. Doane, Past-president George H. Stickney and General-secretary Clarence L. Law. A general consensus of opinion prevailed that the convention, which will be held at the Hotel Sherman, Chicago, on the four days, October 20 to 23, should include numerous features out of the ordinary so as to attract not only a large local attendance but members and visitors from all parts of the country.

At the technical sessions, which will be held Monday afternoon, Tuesday morning, Wednesday morning and afternoon, and Thursday morning, there will probably be less papers of academic interest than formerly and considerably more than usual dealing with commercial application of good lighting. Among these is expected a symposium on the experiences met in different states in applying the state factory lighting codes, which will probably lead to a general discussion bringing out many valuable suggestions for the enactment of such codes in other states. Several papers dealing with factory lighting and equipment therefore are expected. Other papers will present important features of lighting practice in other lines. Military searchlights and use of lighting during the war will be described, if the data on this subject are released by the Government before the time the convention is held.

There is likelihood of one or more joint sessions of the Society with the Illinois State Electric Association and the Illinois Electrical Contractors and Dealers' Association, both of which will hold conventions at the same time. Wm. L. Goodwin will probably address one of these joint meetings, which will be for mutual educational benefit in learning each other's attitude on and method of attacking lighting problems.

Careful consideration is being given to entertainment as well as the business features. Aside from the customary president's reception and subscription banquet, there is planned a special theatre party featuring a dramatization of light and illumination. A special visit to the Chicago Electrical Show is also included, since this will have a large number of very interesting lighting exhibits including a special decorative scheme of illumination for the Coliseum, where the show will be held.

SUMMER COURSE IN FACTORY ORGANIZATION AND SCIENTIFIC MANAGEMENT

Fourth Annual Summer Session at Pennsylvania State College for Two Weeks, August 11 to August 23.

A special course in the above branches will be offered at The Pennsylvania State College on Aug. 11 to 23. No examinations are required for entering the course, but practical industrial experience is desirable. This course is offered particularly for men engaged in industrial activities, as foremen, time keepers, cost accountants, store clerks, members of production or planning departments, superintendents and employment managers. The summer course has been arranged to cover a two weeks' period in order to afford an opportunity to men whose vacation period is restricted to two weeks, to combine a summer outing and recreation with acquisition of practical knowledge in their own field of employment. The instructors are practical men who have had mechanical training, as well as experience in management.

Each morning will be devoted to lectures and discussions on organization, cost accounting and employment management, while the afternoons will be devoted to practical work in the college shops which have been arranged and equipped with a special view to demonstrating and teaching scientific management. The afternoon work will include the making of time and motion studies, the preparation of instruction cards, tool lists, bills of material, route sheets, and scheduling order of work.

The lectures and discussions will be conducted by Maj. Hugo Diemer, professor of industrial engineering at The Pennsylvania State College, whose practical experience includes that of superintendent of the National Motor Vehicle Co., Indianapolis; organization manager for the Goodman Manufacturing Co., Chicago, Ill.; and consulting industrial engineer for many manufacturing corporations, including the Cincinnati Milling Machine Co., Fairbanks-Morse Manufacturing Co., International Harvester Co., and as major of ordnance in charge of important munitions works at the United States Cartridge Co., Lowell, Mass., and the Bethlehem Steel Co.

The afternoon practicum work will be in charge of Lieut. J. O. Keller, who has done time study work at the Aluminum Castings Co., and shop layout work with the Austin Co.

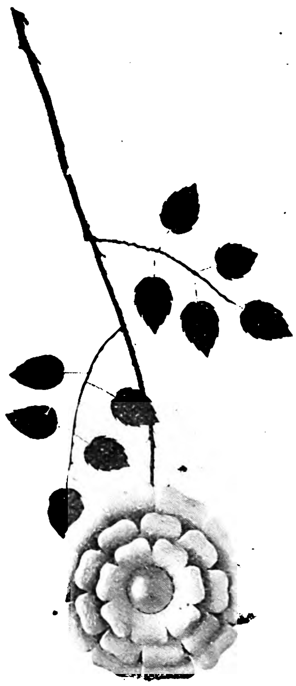
Summer work in the mountain environment of The Pennsylvania State College becomes a pleasure instead of drudgery, providing a summer outing pleasurable, profitable, and economical.

ELECTRICAL DECORATIONS AT PORTLAND ROSE FESTIVAL.

Attractive Illumination of Downtown Streets from Huge Roses with 1000-Watt Lamp Centers.

Electrical decorations were profuse and many of them artistic on the streets and in show windows of Portland, Oregon, during the annual Rose Festival on June 11 to 13. An unique feature of the decorative lighting was the installation on the streets in the business center of 250 Mazda C lamps of 1000 watts each, designed as imitation roses in three colors—deep red, pink and yellow. An illustration of the design, given herewith, shows the frosted lamp bulb as the center of the rose, surrounded by corolla of metal petals, making an imitation rose 30 in. in diameter. The diffusion of the light and the petal coloring were such as to produce to a very good degree the natural tints of the rose. Three such lights were grouped at street intersections and six others were placed between such intersections. Each lamp was hung 30 ft. above the street from the feed wire in such a position as to reflect the blended rays of colored light downward, and to proclaim the glory of the Portland rose to the admiring multitude. The result was a flood of light at night that gave the requisite color effect, and attractive decorations by day.

The 8-foot stem of the imitation rose was the limb of a tree, and the imitation leaves were of tin, so painted as to give the national coloring. The design was that of F. H. Murphy, illuminating engineer of the Portland Railway, Light & Power Co., which furnished the lighting current, and the lamps were installed by the Jagger-Sroufe Co., which carried out the plan of electrical decoration for the Rose Festival Association. The scheme of this kind of decorative lighting was initiated by J. H. Sroufe of that company.



One of the Electrically Illuminated Roses Forming a Feature of Portland's Rose Festival.

LEGISLATURE'S POWER OVER UTILITY RATES REVERTS TO COMMISSION.

The Court of Appeals of New York State has handed down a unanimous decision to the effect that, in cases in which the Legislature had authority to regulate rates, it delegated that authority to the Public Service Commission when it passed the law creating the Commission. The decision was rendered in the case of the International Railway Co., of Buffalo, N. Y., which sought to compel the Public Service Commission to give it a hearing in an endeavor to show that the present five-cent fare is inadequate. The Commission refused the hearing on the ground of lack of jurisdiction. The decision establishes the right of the International Railway Co. to a hearing before the Commission and it is expected such a hearing will be held in the near future.

COMMISSION CITES AUTHORITY TO COMMAND MUNICIPAL UTILITIES.

New Jersey Commission Orders Borough Authorities to Improve Their Electric Plant.

The Board of Public Utility Commissioners of New Jersey has handed down an order directing the borough officials of Madison to make improvements and betterments in the municipal electric plant and system in order to provide safe and adequate service. An inspection was made of the plant to see if operation complied with the standards for service as adopted by the Board, and this led to a contention on the part of the municipal authorities denying the jurisdiction of the Commission over the property. On this point, in its decision, the Board says:

"The observance of the recommendations is resisted by the municipality on the ground that this Board has no power over its electric plant because it confines its service to the municipal limits and does not serve consumers outside thereof. They fear the encroachment of powers reposed exclusively in them.

"The section of the law conferring the authority, however, makes it the duty of the Board to see that its standards of service are maintained alike by public utilities and municipalities engaged in operating public utilities, so that the public served may be insured of safe, adequate and proper service.

"With its experience in matters of standards of equipment and service to be maintained to thus insure safe service, and because of the expertness of its engineers in such matters, both privately and publicly owned utilities rather welcome than resent the inspection of plants, so as to receive the suggestions and recommendations of the Board and its engineers to improve their service.

"We assume the municipal authorities are disposed to furnish the inhabitants of the borough the best service reasonably possible. To do this it is necessary that the things required to be done and recommended in the inspector's report should be complied with."

HOW WE GET THE RURAL LOAD.

Interesting Instance of Power Purchased and Re-sold.

By H. C. Stair,

President, Cambridge (Wis.) Light & Power Co

The last two years have been very prosperous ones for the farmers, especially through the Middle West. Money is plentiful and the growing familiarity with power apparatus, through the general use of tractors and gasoline engines, has created a demand for more power. The gasoline engine has, so to speak, whetted the farmers' appetite for more; it has shown him what the possibilities are and at the same time its limitations and the bother it gives him have made him a live prospect for the convenient and reliable power of the electric line.

Our experience in the central-station business has presented many problems whose solution, I believe, will be of interest to others who have a farming country in their territory. We got into the game in August, 1912, through requests of neighbors that we supply them current from the 110-volt direct-current generator which we had set up in our garage and which was driven by a general-utility gasoline engine. Little by little the business grew and we installed a larger generator and engine in connection with the town's water pumping plant. However, the economical area was restricted to a few blocks and the gasoline engines were costly for fuel and maintenance. Eventually, one of our salesman friends, Harry Caird of Julius Andrae & Sons Co., showed us the possibilities in retailing alternating current purchased from a generating company.

The proposition as we finally worked it out was to build a transmission line 14 miles long from the Edgerton substation of the Janesville (Wis.) Light & Power Co. We purchased the line material, including poles, and secured an experienced construction foreman and crew through Mr. Caird. The work was done during the summer of 1918 and power was turned on Oct. 27, 1918. Along the line we serve a large number of farmers, each of whom pays for his own transformer and protective apparatus. These are all of Westinghouse make and range from 1 to 5 kv-a. The farm load, in addition to lights in house, buildings and yard generally, includes a water pump automatically controlled delivering into a pressure tank for house use, a feed grinder and a washing machine. In some cases a single 3-hp. motor drives a line shaft to which are belted a pump washing machine, churn and separator. Farmers are good customers for appliances and practically every home has an electric iron, tableware and vacuum cleaner.

Our transmission line is 6600 volts, three-phase, and wherever a large block is to be tapped off, we have installed two transformers in open-delta. In the little village of Albion we have two 20-kv-a., 6600 to 220/110 volts, which supply a 15-hp. motor in a creamery and a 30-hp. motor in a grist mill. This mill contains a corn sheller, corn crusher and attrition feed mill, formerly driven by a gasoline engine. We placed an additional pulley on the main shaft and set the motor alongside the engine, thus making the change without rearranging the drive. (In another mill, the owner installed a Sprout-Waldron mill which is driven by two 15-hp. motors mounted on a common bed-plate.) In Albion we serve about 25 domestic consumers, running a wire from the mid-point of one transformer secondary to give 110 volts.

In Cambridge, a town of about 1000 population, we have two 25-kv-a. transformers serving about 130 lighting consumers, as well as a grist mill, a creamery, a garage and the pumping plant. In the creamery we have a $7\frac{1}{2}$-hp. motor driving a separator, churn, deep-well pump and cream pump. It displaces a steam engine and the owner says that even though he must keep his boiler in service for sterilizing and water-heating, he finds the motor a paying investment in convenience. In the garage is a 5-hp. motor driving various machines, and in the pumping plant is a 10-hp. motor supplying water to the town.

So far we have shut down two low-voltage gasoline-electric sets and in the near future expect to shut down five more. We consider these plants as "trail breakers" for central-station service; they are not powerful enough for the heavier farm service and when central-station power is available, the private plant is out of the running.

Our policy has been to consider the entire project as a money-making proposition. However, as we have secured most of our funds from our consumers, they share in our profits. Farmers are required to pay all costs of connecting to our main line, and we have three short branch lines for which the men served dug the pole holes and paid for all the material.

We do not maintain a "trouble man" but when necessary secure linemen from Janesville. My supervision, bookkeeping, etc., takes about one-fifth of my time. The electric company does not sell appliances or do wiring, but I devote part of my time to the Cambridge Electric Co., which renders these services.

We buy about 8500 kw-hr. per month at the regular wholesale rates and sell it on a four-step graduated scale for domestic use.

POSSIBILITIES FOR ADDITIONAL OUTLET BUSINESS SHOWN.

That certain, definite concerted steps must be taken to provide the necessary outlets for the full utilization of electrical energy is the view of F. H. Scheel, of the Public Service Co. of Northern Illinois, who points out that in analyzing ways and means of promoting this purpose, we find the field naturally divides itself into three separate and distinct units:

"(1) The new home proposed or under process of construction.

"(2) The house already wired, but not equipped with appliance outlets.

"(3) The old residence not yet wired.

"Taking them as they are listed, the first calls for some missionary educational work by the central station among those who have to do with new buildings, such as the architect, general contractor and electrical contractor; also more attention to the wiring specifications of new buildings on the part of the central station commercial department.

"The instalaltion of added outlets in premises of existing customers can be materially increased.

"(a) By combining the offer of outlet and the appliance, particularly in the case of vacuum cleaners, washers, ironing machines and portable lamps.

"(b) By carrying this class of wiring on deferred payments the same as on wiring jobs.

"(c) The use of duplex receptacle, thus permitting two attachments at the cost of one outlet.

"(d) By promoting the sale of electrically wired tea tables.

"(e) By paying salesmen commission on this business as well as on new contracts.

"In the old residence not yet wired, the matter is entirely in the hands of the central station and the electrical contractors. The numerous advantages and comforts of electrical appliances have been a big talking point in getting the prospect to wire. There is, therefore, no logical reason for insufficient appliance outlets. Central stations should—

"(1) Line up the contractor on equipping a home for electric service as well as electric lights. It means more wiring for him.

"(2) Govern the amount of salesman's commission partly by the number of appliance outlets.

"(3) Where price prohibits extra outlets, as in bedrooms, use wall brackets with socket in canopy, thus using same outlet.

"(4) If one or two outlets are given as a premium on special housewiring campaign, make it the appliance outlet.

"(5) Keep a comparative record of outlets secured by each salesman.

"In a few words—think it—talk it—practice it—tie up the idea with our general advertising by some catch word slogan. For want of a better one, I suggest 'More Sockets for More Service.'"

CHRISTMAS SALES FOLDER NOW READY FOR PUBLICATION.

Sample copies of "Electrical Gifts," a Christmas advertising folder prepared by the Commercial Section of the National Electric Light Association are now being distributed. This folder, which features electrical goods as Christmas gifts and briefly describes the many advantages which they offer for this purpose, is attractively printed in four colors and should be of great assistance in creating a big demand for electrical gifts. Many of the more common electrical appliances are illustrated and described with alluring captions. Space is provided on the back of the folder for imprinting the name and address of the company that distributes them.

A very large edition of this business-getting folder will be printed shortly, so that shipments can be made well in advance of the Christmas season. In this connection companies desiring copies are especially urged to order them now, for the imprinting, if done when the folder is on the press, enables the association to quote lower prices. These prices range from \$4 per 100 in small lots to \$16.50 per 1,000 in quantities of 50,000 and over.

Orders received after edition is printed, necessitating additional labor and expense, will be filled, if possible, but at increased prices. The advisability of estimating the requirements and ordering now is therefore evident.

Requests should be made to the Publications Committee, Commercial Section, 29 West 39th street, New York City.

ELECTRIC OVENS COUNTERACT SERVANT SHORTAGE.

At the manufacturers' exhibit of the Ohio Electric Light Convention, Cedar Point, O., July 15 to 18 inclusive, Miss Sigourney J. Frush, demonstrator for the Westinghouse Electric & Mfg. Co., baked pies and cakes and candy with a Westinghouse oven.

Miss Frush backed her statements with deeds, keeping an interested gathering around her as she explained the automatic features of the electric range, how it became a "fireless cooker" and how simple it was. Miss Frush said the servant problem would be less serious and less often discussed, if people only realized the cleanliness and convenience of the electric range.

Operating Practice

Testing and Setting of Relays—Complex System Trouble Due to Generator Breakdown—Protecting Rubber Gloves

PRECAUTIONS TO BE FOLLOWED IN TESTING AND SETTING RELAYS.

Application of Test Current and Method of Timing Important Factors in Testing.

Costly and ideal systems of relay protection are of little value unless the relays installed are properly tested and checked with sufficient frequency and accuracy to assure that they are in proper working conditions. In this connection pertinent advice was given in the paper on "Transmission-Line Relay Protection," presented before the A. I. E. E. convention recently. A large part of this paper was abstracted in the issue of July 5.

In order to secure the best results from the relays, it is desirable to make a complete check on the current and time settings of each relay on the first installation and at least once every six months thereafter. Although the time for making these tests is determined to a large extent by the operating conditions, best results will be obtained if a general plan is worked out for performing these tests at regular intervals.

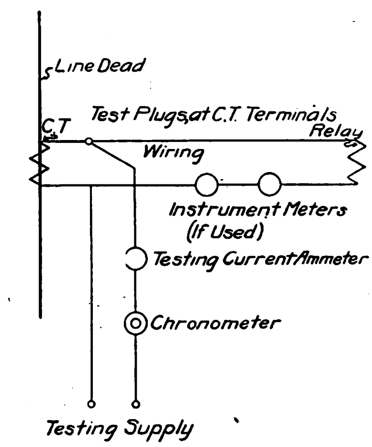

Fig. 1.—Diagram of Connections for Supplying Testing Current to Secondary Terminals of Current Transformer.

If selective operation is to be obtained from the relays the greatest care and precautions must be taken in making these tests. The tests should be performed under conditions as nearly equal to the operating conditions as possible which makes it desirable to include the wiring and complete relay equipment in this test.

In this test, the test current should be applied, wherever practicable, to the primary of the current transformer. Where it is impracticable to do this the testing current may be supplied to the secondary terminals of the current transformer with the current transformer left in circuit as a shunt, as shown in accompanying wiring diagram. The results obtained under these conditions very closely approximate those under short circuit and serve to check the relay wiring and current transformer, as well as the relay. This will detect any short circuit in the current transformer or wiring and any open circuit in the wiring but open circuits in the transformer coils should be determined by a separate continuity test.

The degree of accuracy obtained when the relay is tested alone is dependent upon the type of transformer used and the secondary load. The error in this method is due to the high magnetizing current of transformers (especially with the low-ratio single-turn type on heavy secondary loading) on the heavy short-circuit conditions. As an example, a 40-volt-ampere secondary load on a current transformer at full load imposes a 16-kv-a. load under short-circuit conditions of 20 times full load. This, in many cases, is above the saturating point of the transformer and the ratio breaks down badly.

The time-current curve of a relay is affected by the nature of the secondary load or by the characteristics of the current transformer. It is, therefore, desirable that each individual relay be tested with current such as would be occasioned by short circuit. At least three points along the curve should be taken, one of which should be approximately 150% of the minimum value, one at as near maximum short-circuit current as the testing equipment will permit, and one intermediate point. The time should be taken by a chronometer or cycle counter which will eliminate the personal equation of the operator. The method of timing by a stop watch is entirely inadequate for close relay settings.

An additional inspection should be made about every month for continuity of trip circuits (where this is not indicated by lamps) and for dirt or mechanical defects. Moreover, where conditions will permit, the relay should be operated to trip the circuit-breaker. In case of bellows relays the bellows should be oiled with neatsfoot oil to prevent hardening.

ACCIDENT TO TURBOGENERATOR CAUSES MANY TROUBLES.

Hunting of Systems and Exciter Troubles Follow Breakdown of Field and Armature.

On a big central-station system there were six 10,000-kw. turbogenerators on one sectionalized bus operating in parallel with three 10,000-kw. and one 25,000-kw. turbogenerator on another section of bus, these two bus sections carrying about 45 and 55% of their rating, respectively. At another station, tied into the above station over tie-lines, were four more turbogenerators carrying about 60% of their rated load. At a third station three large units, of 20,000 kw. and above, were operating at about 70% rating. This station was tied in with the other two stations over tie-lines.

One of the field end-plates of one of the 10,000-kw. vertical type generators became detached and fell in between the field and armature. This resulted in the coils of both field and armature being cut, causing a short-circuit on the 9000-volt windings and the exciter side of the machine. The defective machine was cleared from the system almost immediately.

Directly following the burn-out of the unit and the disturbance created, several of the turbogenerators in the same station tripped out due to overspeed; a number of synchronous converters in various substations on the system shut down. One rotary burnt up. The system began to hunt and persisted for about 18 minutes after the turbogenerator broke down, the frequency varying considerably above and slightly below normal, and the voltage going from 7000 to 8800 volts in heavy swings. The wattmeters on the tie-lines between the three generating stations swung continuously from one end of their scales to the other, indicating heavy interchange of current between stations.

After this had continued for about 18 minutes conditions suddenly quieted down, although for no apparent reason, and the system pressure rose to 9400 volts, about normal.

It was then found that the reactances in the tie-lines between stations have been so hot as to oxidize at the surface of the cables (they were of the bare cable, concrete core type), and the insulating compound on the frame work was blistered. Tie-line ammeters and wattmeters on one end of a tie-line were badly damaged.

It was later discovered that one tie-line solenoid-operated circuit-breaker and one high-voltage feeder circuit-breaker were in the half-open position, the solenoid of this latter being burned open and grounded. It then became known that the negative return from the oil circuit-breaker of one of the 10,000-kw. turbogenerators has grounded and burnt open, and that a dead earth has occurred on the exciter system.

One explanation of the cause of the 18-minute surge or hunting between the three generating stations is that the breakdown of the defective turbogenerator had resulted in a phase displacement between the three systems. As these systems were tied-in together through tie-lines, the reactance prevented sufficient synchronizing current to flow between systems to bring the systems into phase again. And the disturbance continued until the abnormal conditions subsided and the system attained its equilibrium again. Whether it was excess resistance or too much or too little reactance might be a mooted question without investigation, of course.

The trouble to the exciter system was doubtless due to the exciter system being subjected to high potential to ground, it causing breakdown at several places, and possible weakened insulation at others. Contact between armature and field when the field end-plate cut into the coils caused direct contact between the 9000-volt system and the exciter system, of course, and a consequent breakdown in the immediate vicinity.

While only a few of the salient features of the trouble have come to hand, and these are not complete, sufficient is known to bring out the facts that hunting between systems is not yet a matter that can be fully explained nor guarded against under unexpected conditions. Moreover, the above incident shows that exciter systems may be subjected to direct contact as well as to induced high potentials, hence it might be well to give exciter systems the respect given to circuits of higher potential, and perhaps at the same time furnish a means at individual generators to prevent high potentials dissipating themselves promiscuously throughout the exciter system.

PROMOTING USEFULNESS AND SAFETY OF LINEMEN'S RUBBER GLOVES.

Container Hung from Belt Is Advocated.

Rubber gloves are now furnished by most central station and electric power companies to their linemen. Safety first rules dictate that they be used whenever work is being done on voltages above 600 volts. Although wooden poles have an insulating value, the wood is not to be depended upon and rubber gloves are considered as absolutely necessary for the lineman.

As a matter of fact, while most companies and municipalities furnish rubber gloves to their men free, these gloves are not always used. Frequently in cases of electrocution it is brought out that the man killed did not use his gloves or did something else that he ought to have known he should not do.

One reason that rubber gloves, although available, are not used, is because they are not always conveniently at hand. Some linemen tuck their rubber gloves in their trouser pocket while climbing the pole and fixing their belt. Others tuck them between their belt and body. One of the chief reasons linemen tend to not use their rubber gloves is because they usually have no convenient place to keep them unless on their hands, and they should be worn only when actually needed because otherwise they may be punctured by splinters on poles, nails and similar sharp projections. Moreover, rubber gloves enclose the hands and keep out air which results in sweating, which in turn rots the rubber and causes personal discomfort.

A policy that has much to recommend it is that of furnishing weatherproof canvas bags of such a size that the rubber gloves may be slipped into them without folding or crumpling up, either of which tends to cause cracks in the rubber. These bags should have a loop or two loops so located that the bag may be hung from the lineman's belt. The top should have a flap that comes down well over the opening of the bag so that rains will not enter the bag and the lineman can easily close the bag by merely pressing the flap against the side.

If companies would furnish their linemen with these bags when they allot the gloves there would be less tendency on the part of the men to work without their gloves on their hands, since the gloves would always be available at a convenient place, like all the other tools in the lineman's belt. The gloves would be less likely to be damaged due to mechanical injury, one glove of a pair would be less likely to be lost. The gloves would have a longer useful life and the element of danger would be less.

AIR-COOLED BRICKWORK REDUCES CLINKER TROUBLES.

By designing the furnace setting for circulation of air from beneath the fuel bed through the brickwork into the furnace, there is less need to chisel frozen clinker from the walls; coke is burned off the clinker, thereby reducing loss of carbon; heat units lost by radiation through the side walls are largely recovered again; and considerably less labor, time and expense are required to keep furnaces in good condition. Furnaces are able to maintain rates of combusion and remain in service longer without shutdown and the life of the brickwork of furnace walls is greatly increased.

Contracting-Construction

Some of the Methods Employed in the Conduct of a Successful Electrical Machinery Repair Business Explained

WHAT CONSTITUTES EFFICIENCY IN REPAIR BUSINESS.

Paper Presented at Recent Convention of National Association of Electrical Contractors and Dealers.

By A. Penn Denton,
Denton Engineering & Construction Co., Kansas City, Mo.

In the development of the contractor-dealer's business during the period of reorganization and readjustment since October, 1917, when Wm. L. Goodwin pointed the way to larger fields of endeavor and greater possibilities for them, there has come to many contractors a realization of the opportunities to be had in the sale of used and rebuilt electrical machinery and in the repairs of such equipment. It is not the intention to discuss the business of selling used machinery which has been found profitable, but to give briefly the result of the experience of the author's company in repairing and rebuilding electrical equipment and to point out how important efficiency is in this line of work.

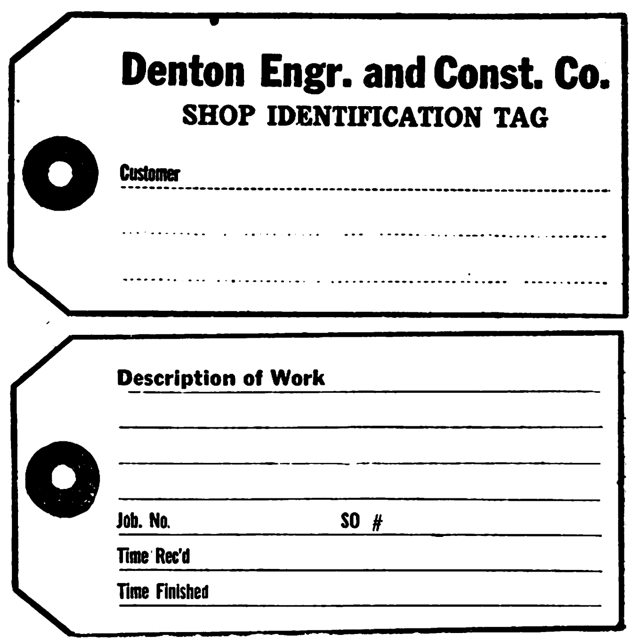
The repair shop of the contractor a very short time ago was not much more than a corner of the stockroom. In some cases he had a small room set aside for this work but the one or two men employed at that time did not appear to him of sufficient importance to provide these men with either the proper place or equipment so that they could make a showing that was at all comparable with the wiring and construction department. This company passed through this stage of development and then began to realize that by giving its machinery repair department just a small part of the attention the construction department was receiving, in a short time it began to show real results and looked like a paying proposition. It then turned its attention to the department with the idea that it should become as important a factor on the total business as the construction department. The plan followed started with a careful study of the best way to get the machinery repair business and the proper way to handle it after it was secured.

It was found that three important factors were essential in going after repair business. It was necessary to: First, advertise in the local newspaper and the trade papers. The repair business is entirely different from contracting or merchandising in that the average consumer who needs such service has no idea of where he can go to get a good job of repair work done, and in the case of the large industrial plant usually has done its own repair work or sent it to the repair shop of the manufacturer of its particular electrical equipment. It found also that an excellent advertising medium was a series of letters sent to the customers, enclosing advertising blotters. The third and most important fact in the now to get the business plan was found to be a good live salesman who was sent out to sell what was termed as electrical repair service and it was found by carefully following up the advertising that the company was able to get business



Front and Back of Tag Attached to Machines, Which Facilitates Identification.

from companies who formerly had said they were not in the least interested. A salesman of this service need not call oftener than once a month on the larger plants and once in 60 days on the small plants. By persistently following this plan any dealer can get a share of the repair business in his community.

When the business is secured, the next part of the scheme is to be able to handle it properly and efficiently. It is even necessary in some cases to give better service, certainly a prompter service than the manufacturers' repair shop, if the business of the plant or customer who has felt he was fairly well taken care of before you sold him, is to be held. It is therefore of primary importance to have a good organization. A manager of the repair department is required, someone who can be held entirely responsible for the proper handling of the work, and this party may be at the same time a salesman. The Denton company has found the duties of the manager and salesman combined nicely and worked out much the same as in its construction department where the department manager is responsible for getting all business and supervising the work after it is secured. It is also necessary to have a service man who can assist with the purchasing of the repair department materials. Then, most important in the repair shop organization is the foreman of the shop, who must be a man of practical and technical experience, a good executive in handling men and a person who is willing to co-operate with other employes.

It is also necessary to have a good stockman and a careful accounting and billing department. Promptness and accuracy in sending invoices makes the repair business a pleasure because a large part of the work is labor and all repair business should be handled on a strictly cash basis. In this connection it was found that a most important adjunct to the organization was proper forms for making records of each job handled. Some of the forms developed are illustrated herewith.

The importance of such an organization is in a measure secondary to the proper equipment of the shop. It has been found that the right kind of equipment such as coil winding and taping machines, a baking oven, coil dipping tanks, etc., are an absolute necessity in a shop that expects to be any factor at all in the repair business because without such equipment the work cannot be efficiently handled and if not efficiently handled it is not profitable. It is therefore necessary to invest a considerable sum of money in the proper kind of equipment and for this reason no contractor should undertake to go into the repair business who has not sufficient capital.

New Appliances

Intermediate Size Dungar Battery Charge Set—Small D. C. Instruments—Auto Lighting System—Entrance Switch

The New "Four-Battery" Tungar Rectifier.

The General Electric Co., Schenectady, N. Y., has just placed on the market a new "Four-Battery" Tungar battery charger, designed to meet the needs of the automobile dealer or garage owner, who desires to do a small amount of battery charging.

As its name indicates, this new size is an intermediate between the big 10-battery Tungar outfit for service stations and the small Tungar for home use.

The "Four-Battery" Tungar will charge from one to four three-cell batteries at a maximum of 5 amperes. The rate can be varied from 3 to 5 amperes. It operates from a standard 115-volt, 60-cycle alternating-current circuit.

The essential parts are a bulb for rectifying the current and a transformer for reducing the voltage, both of which are contained in an attractive sheet-

Tungar "Four-Battery" Charging Rectifier and Controller.

metal case. An ammeter, for reading the charging current, and a dial switch are mounted on the front of the case.

The device is very easily installed. Simply mount it on the wall with four screws and connect the leads to the alternating-current supply. The operation is very simple. Connect the direct-current leads to the batteries. Turn the dial switch to the right until the ammeter reads the desired charging current. To stop charging, turn the switch back.

There are no moving parts in the Tungar set, and it requires no oil or grease. It has been approved by the fire underwriters, and can be safely operated over night without attention. If the alternating-current supply fails, the batteries cannot discharge back through the rectifier. When the current comes on again, the Tungar will commence charging automatically at the same rate as before.

Automobile Lighting With a Single Lamp.

Ira T. Swartz, president of the Swartz Electric Co., Indianapolis, Ind., has developed a new method of automobile lighting, to be known as the "wireless-lite." Although the conventional number of head lamps, side, dash and tail lamps are provided, only one electric incandescent lamp is used in the entire system. This feature gives the new system its name, as all exposed wiring is eliminated. A lamp of high candle-power is employed as the source of illumination. The light from this single lamp is, by a clever arrangement of mirrors and lenses, distributed to the various points. Various adjustments of the light can be made by the driver from a control lever on the dashboard. The system is said to be very efficient and economical.

Pocket-Size, Portable Direct-Current Instruments.

The Roller-Smith Co., 233 Broadway, New York City, announces a new design of its small, pocket type, direct-current "Handy" ammeters, voltmeters and volt-ammeters. This instrument was in the course of development for many months, during which time there was constant experimental work to determine the best design and materials suitable for an instrument of this class. The result is one of which the company is justly proud. The new "Handy" instrument is small, compact and light. It was designed with the idea constantly in mind that accuracy and reliability must be maintained even under the most severe conditions.

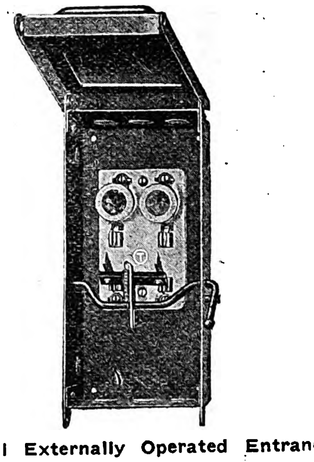
This line is very complete, comprising milliammeters and ammeters up to 50 amperes; millivoltmeters and voltmeters up to 150 volts and volt-ammeters up to 50 amperes and 150 volts, all self-contained. The ranges are increased beyond that by the use of appropriate shunts and multipliers. These instruments are of the permanent-magnet, moving-coil type giving uniformly spaced scale divisions and dead-beat or instantaneous indications. There are two magnets that are well aged and made of high-grade tungsten steel. A very rigid but light-weight moving coil is used. It swings on hardened steel pivots in sapphire jewel bearings. The staff of the moving system is stiff and not likely to bend and cause friction. A rigid aluminum pointer of the knife-blade type is used. The scale is 2¾-in. long and usually divided into 50, 60 or 75 divisions. All instruments are individually calibrated and guaranteed accurate within 1% of full scale value.

A brass case encloses the instrument's mechanism and scale; it receives a black rubberoid finish. The instrument dimensions are 4 in. wide by 5 in. high, by 2 in. deep. On the average instrument the weight is about 20 ounces. Instruments are available in this line with double or even triple ranges of scale markings at slight additional price. In the case of volt-ammeters it is possible to obtain instruments having even three volt and three ampere ranges.

These instruments are well adapted for general commercial testing of various kinds as well as for school and college laboratories where a small and quite accurate, but moderate-priced instrument is desired.

Enclosed Service-Entrance Switch.

Service switches must be installed at a point as close as possible to where the service entrance is made to the building. They must be of reliable type so as to permit quickly cutting off of all



Trumbull Externally Operated Entrance Switch.

current from the building in time of emergency or when extensive repairs are necessary to the interior wiring. They should also be properly safeguarded to protect the occupants of the building from coming into contact with exposed conducting parts. This necessitates a suitably enclosed switch that can be externally operated without opening the enclosure.

These various requirements are incorporated in the externally operated service switches illustrated herewith. They are made by the Trumbull Electric Manufacturing Co., Plainville, Conn., and consist of its regular switch No. 701 in a No. 16 gauge steel box. It is known as No. 5741 and is rated 30 amperes, 125 volts and is made for plug fuses. The switch is of the quick-break type and a marked improvement over the ordinary service switch from the safety standpoint.

Trade Activities

Okonite Holds Annual Outing—Wheeler Condenser & Engineering Elect Officers — Electric Furnace Installation

Electric Furnace Installation in Navy Yard.—An interesting development recently took place at the League Island Navy Yard, Philadelphia, when the first heat of steel was made in the Greaves-Etchells furnace recently installed by the Electric Furnace Construction Co.. Finance building, Philadelphia, in the new foundry. The foundry itself is said to be one of the most modern and up-to-date in the country, and the manufacture of steel in this yard opens up very interesting possibilities for large future development.

Philip H. Ward, Jr., formerly general manager and secretary in charge of sales and exports of the Chelten Electric Co., announces that he has severed his connections with that company and has organized the Ward Electric Co., Inc., Philadelphia, with headquarters in the Philadelphia Stock Exchange building. The new corporation will manufacture for domestic and foreign distribution, an extensive line of electrical supplies and specialties, including knife, push button and surface snap switches, flush receptacles, new code and plug fuses, porcelains, ground clamps. It will be the aim of the new organization to furnish to the trade products of superior merit, promptly, at attractive prices.

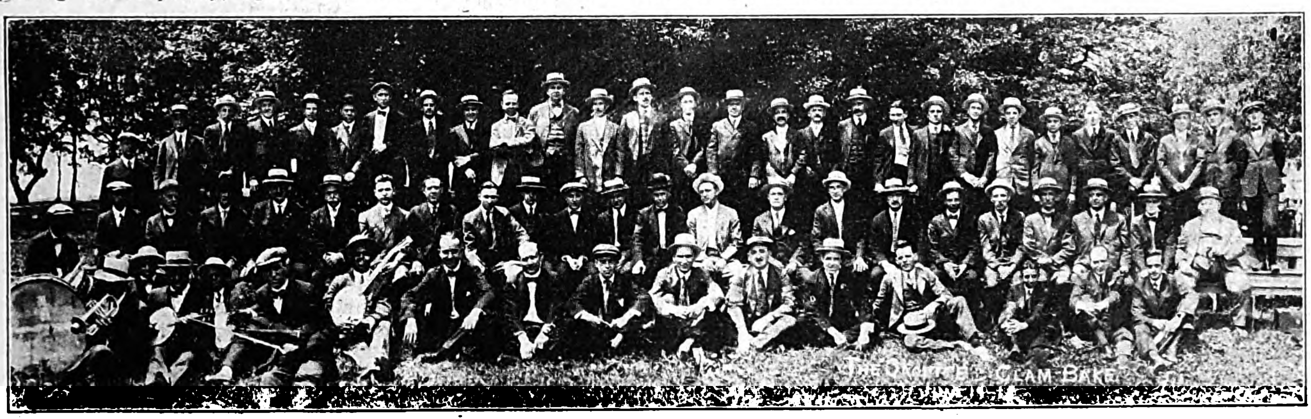
Dayton-Dowd Co., Quincy, Ill., manufacturer of centrifugal pumps, is distributing Bulletin No. 240, illustrative and descriptive of its redesigned line of type CS single-stage, double-suction type centrifugal pumps. These pumps embody the most advanced principles of design and represent among the most modern, high-grade, standardized, highly efficient machines on the market. They are simple in design and rugged in construction, insuring reliability in service and durability. The bulletin contains several curves made from data resulting from shop tests showing the characteristics of several sizes of Dayton-Dowd pumps; also a table giving the capacity, speed and efficiency of the type CS single-stage double-suction pumps.

The Belden Manufacturing Co., 2300 South Western avenue, Chicago, Ill., has recently let contracts for the erection of a new four-story factory building at its new plant location at Kilpatrick avenue and West Congress street, Chicago. This will make the third building erected by the company on this tract of land. The erection of five more buildings is contemplated in the next few years. The new building will be used for expansion of the different magnet wire departments.

The B. & K. Manufacturing Co., New Britain, Conn., manufacturer of pole line hardware and pressed steel construction specialties, announces the appointment of David C. Rosetahl, formerly affiliated with the National X-Ray Reflector Co., as general sales manager of its portable lamp department. The company has adopted a new plan for merchandising its product throughout the country with the idea of expanding its organization in every large city in the United States and Canada and with this end in view has engaged Mr. Rosetahl as its general sales manager. For the past six months the designing department of this organization has been very active in making up illustrations of novelty portable lamps and it is today one of the representative manufacturers of this line of electrical equipment.

The Okonite Co., Passaic, N. J., well known manufacturer of insulated wires and cables, has inaugurated the custom of giving an annual outing to its office and factory staff. This year the gathering took the form of an old-fashioned Rhode Island clam-bake and was held at College Point, Long Island, with an attendance of 65. The group picture presented herewith shows President H. Durant Cheever near the center of the first row of chairs and ex-President Willard L. Candee, one of the founders of the company, seated at the right of the same row. General Sales Manager J. D. Underhill and Treasurer W. H. Hodgins are to be seen standing at the left of the last row.

Wheeler Condenser & Engineering Elects Officers.—At a meeting of the board of directors of the Wheeler Condenser & Engineering Co., Carteret, N. J., on July 8, J. J. Brown, formerly vice-president and general manager, was elected president, succeeding Charles W. Wheeler, recently deceased. H. S. Brown, of 50 Congress street, Boston, was elected vice-president. H. S. Brown has been associated with the Power Specialty Co., 111 Broadway, New York City, for the past 15 years, the greater part of the time as New England manager for that company. During the war he was active with its government work with headquarters at Washington and Philadelphia. He is also president of the Brown-Ferries Co. of Philadelphia. The business of the Wheeler Condenser & Engineering Co. has more than quadrupled during the past ten years under the management of J. J. Brown, and the manufacturing capacity of the plant has been correspondingly increased. One important addition has been the construction of a large tube mill for the manufacture of seamless drawn tubing of brass, copper and special mixture. In this mill the record output of nearly one million pounds of condenser tubing in one month was recently made. This tubing is used not only in Wheeler condensers, evaporators, reboilers etc., but it is also made in large quantities to customer's specifications for American trade and for exporting. At this writing, in the condenser department, 16 condensers of approximately 50,000 sq. ft. cooling surface are being made. Among other products of this well known company are: natural and forced draft cooling towers; centrifugal pumps; vacuum pumps — patented steam jet, turbo dry rotative and Wheeler-Edwards; jet condensers; heaters; exhaust relief valves; vacuum pans, and single and multiple effect evaporators.



Office and Factory Staff of the Okonite Co. at Annual Outing.

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Bar Mills, Me.—Bar Mills Power Co. is having plans prepared for extensions and improvements in its hydroelectric power plant, including considerable remodeling work.

Boston, Mass.—Nelson Corp. will build a one-story, 400x500 ft. manufacturing plant, a two-story, 80x400 ft. receiving building, a four-story, 60x120 ft. office building and a two-story, 84x87 ft. power house.

Boston, Mass.—Nova Scotia Tramways & Power Co., Halifax, Nova Scotia, has arranged for a note issue of $1,000,000, the proceeds to be used, in part, for extensions and betterments in its plant and system. The work will include addition to boiler plant for increased capacity, extensions to gas plant and system; new rolling stock, and other equipment. The company, managed by the Stone & Webster Corp., Boston, operates the electric light and power, and other public utility properties at Halifax, Dartmouth, etc.

Brockton, Mass.—George E. Keith Co., has commenced the construction of the proposed one-story power plant at its local shoe manufacturing works, to be used for factory operation. The structure will be 60x70 ft., and will be connected with the factory by means of an underground tunnel. The structure with equipment will cost about $100,000.

Quincy, Mass.—Fire recently damaged the plant of the Quincy Electric Light & Power Co. The loss is estimated at $15,000.

Whitman, Mass.—Edison Electric Illuminating Co. of Brockton has disposed of its former power plant building at East Whitman to the National Foundry Co. The structure was erected about 30 years ago by the Whitman Electric Light & Power Co., and was employed for furnishing service in this district. About fifteen years ago the plant was purchased by the Edison company; following arrangements for taking power from Brockton and later, from East Bridgewater, the plant was closed down and has not been operating for some time past.

Hartford, Conn. — Arrow Electric Co. will erect a two-story addition to its factory to cost $45,000.

Hartford, Conn.—Twin State Gas & Electric Co. has arranged for an increase in its capital to provide for additional operating funds, as well as proposed extensions and betterments.

New Haven, Conn. — Yale Tire & Rubber Co., Highwood, has broken ground for the construction of a one-story power plant at its works, to be provided with a brick or reinforced concrete stack.

Belport, N. Y.—Northern New York Utilities, Inc., contemplate the erection of a high-tension steel tower transmission line from the company's power house to Towville, a distance of 20 miles. The estimated cost of this extension is $200,000. H. G. Davis, Light and Power building, Watertown, is chief engineer.

Binghamton, N. Y.—L. P. Amslie, 41 Laurel street, Johnson City, N. Y., has received the electrical contract for work in a new two-story school building at Hooper, near Binghamton.

Central Islip, N. Y.—Bids have been taken by the State Hospital Commission, E. W. Elwood, secretary, Capitol building, Albany, for the installation of the proposed new boilers, stoker equipment, etc., at the Central Islip State Hospital. Lewis F. Pilcher, Capitol building, Albany, is State Architect.

New York, N. Y.—Henry L. Doherty & Co., 60 Wall street, have announced the establishment of a new branch office in the Morris building, Philadelphia, Pa., to be placed in charge of Ralph Runyan. The company is now operating 14 branches in various cities.

New York, N. Y.—Western Union Telegraph Co. has completed negotiations for the leasing of the entire fifth floor of the building at 395-99 Broadway, located at Walker street, to be used for new executive offices. The lease aggregates $100,000 in rentals.

New York, N. Y. — International Telephone Sales & Engineering Corp., a Delaware incorporation, has filed notice of authorization to operate in New York with a capital of $3,800,000. R. S. Gould, 37 Wall street, is corporate representative.

New York, N. Y.—The Wills Egelhof Co., Inc., 101 Park avenue, has been awarded the general contract for the erection of the Citizens National Bank building located at Covington, Va. Alfred C. Bossom, New York City, is architect.

New York, N .Y.—Wappler Electric Co., Inc., 173 East 87th street, manufacturer of batteries and other electrical equipment, has awarded a contract to the Turner Construction Co., 244 Madison avenue, for the construction of its proposed three-story reinforced concrete manufacturing plant on property recently acquired on Harris avenue, near the Queensboro Bridge, Long Island City. The structure will provide a total manufacturing area of about 50,000 sq. ft. The company recently increased its capital from $750,000 to $850,000.

Ossining, N. Y.—Contract has been awarded to the Van Wagoner Linn Construction Co., 143 East 27th street, New York, by the New York Commission on New Prisons, Hall of Records, New York, for electrical work in connection with the construction of proposed additions to Sing Sing Prison, Ossining. The electrical work is estimated at $16,365.

Potsdam, N. Y. — Final contracts have been awarded by the State authorities for the construction of the proposed boiler plant at the Potsdam Normal School, the H. M. Week Co., New York, being the building contractor. Contract for electrical work has been let to the Hudson Electric Engineering Co., New York.

Troy, N. Y.—In connection with the construction of a large new local armory building now under consideration by the State Armory Commission, a quantity of electrical equipment will be required, the proposed structure being estimated to cost $475,000. Col. Franklin W. Ward, Telephone building, Albany, is secretary of the commission. Lewis F. Pilcher, Capitol building, Albany, is state architect.

Bernardsville, N. J.—Following a severe electrical storm, the lines of the New Jersey Power & Light Co., at Brookside, near Mendham, were thrown out of commission. This is the high-tension system furnishing service at Bernardsville, and the city was in darkness for about 24 hours.

Bloomfield, N. J.—Bloomfield Electric Shop has filed notice of organization to operate at 596 Bloomfield avenue. Leon G. Frank, 1395 Brestow street, New York, heads the company.

Jersey City, N. J.—Modern Gas & Electric Appliance Co., 568 Newark avenue, has filed notice of organization to manufacture electric and gas fixtures. Frank Tury heads the company.

Newark, N. J. — Rainbow Electric Co., 258 Chadwick avenue, has filed notice of organization to manufacture electrical specialties. Samuel Rubinstein is head.

Newark, N. J.—Springfield Light Co. has filed notice of organization to manufacture electric lighting fixtures, with works at 452 Springfield avenue. Harry Shapiro, 115 16th avenue, heads the company.

Newark, N. J.—George J. Crosman, operating a plant at 139 Jackson street for the manufacture of composition specialties, will install a new boiler and engine plant in connection with his works, to be located on Astor street.

Paterson, N. J.—Business interests located on Main street are negotiating with the Public Service Electric Co., for the installation of a new white way street lighting system along the thoroughfare.

Perth Amboy, N. J.—Jersey Central Traction Co. has been ordered by the Board of Public Utility Commissioners to make improvements and extensions in its plant and system for general betterment in service. The work includes improvements on the Keyport-Perth Amboy Division, the Matawan-Keyport Division, and at Atlantic Highlands.

Plainfield, N. J.—A new company is being organized to be known as the New Jersey Trackless Trolley Co., to construct and operate a trackless trolley line between Plainfield, South Plainfield and Metuchen. The estimated cost of the new system, including overhead lines, poles, etc., is $125,000. Among the first subscribers to the new company are the Spicer Manufacturing Co., Charles H. Frost and Tepper Brothers. The Public Service Railway Co. has refused to extend its lines along this new route, holding that it would cost about $140,000 and the company was not in a financial position to make the investment.

Trenton, N. J.—Trenton Electric & Conduit Co. has filed plans for the erection of two new one-story additions to its works at 1-3 Tyler street, to cost about $10,000.

Trenton, N. J.—A 10-ton electric traveling crane and other electrically operated equipment will be installed in the new one-story machine addition to be erected at the works of the John E. Thropp's Sons Co., Lewis street, manufacturer of tire-making molds and machinery.

Trenton, N. J.—The Board of Public Utility Commissioners has ordered the Trenton & Mercer County Traction Co. to make a number of improvements and additions in its system in different parts of the city.

Trenton, N. J.—The Board of Public Utility Commissioners has granted permission to the Trenton & Mercer County Traction Co. to dispose of property, aggregating about 37½ acres of land in Hamilton Township, to the Pennsylvania & Newark Railroad for a consideration of about $15,000.

Washington, D. C.—The Bureau of Yards and Docks, Navy Department, will build an addition to its electric power plant at Paris Island, S. C., to cost about $10,400.

Bristol, Pa.—The Borough Council and local citizens are negotiating with the Eastern Pennsylvania Gas & Electric Co., for the operation of its auxiliary plant, installed in co-operation with the borough, during non-service periods from other sources of supply. The auxiliary plant was designed to be used in connection with the local street-lighting system, as well as for other service.

Catasauqua, Pa.—An ordinance is being considered by the Common Council providing for a bond issue of $50,000 for the construction and operation of a municipal electric light and power plant.

Easton, Pa.—Pennsylvania Utilities Co. will soon commence the installation of three new boilers at its Dock street plant for increased capacity. The units will have a total capacity of about 2300 hp.

Pittsburgh, Pa.—The Public Service Commission has approved the merger of a number of electric companies operating in Beaver county with the Harmony Electric Co., to be operated as a unit system in the future.

Pittsburgh, Pa.—Pittsburgh Model Engine Co. has commenced the erection of a plant on Lexington avenue, near McPherson street, to cost about $200,000. The works will comprise a one and two-story building, 40x180 ft., and 60x320 ft., respectively.

Pittsburgh, Pa.—Considerable electrical equipment and machinery will be required in connection with the proposed additions and improvements to the local water supply and sewerage systems. Bonds have been voted by the citizens for $1,401,000 and $1,341,000 for the work, covering water and sewerage systems, respectively. The Board of Public Works will be in charge of the project.

Pittsburgh, Pa.—In connection with its new electric generating plant at Springdale, estimated to cost about $5,000,000, the West Penn Power Co., Pittsburgh, has developed plans for mining coal under the Allegheny river at this point. As the coal is mined and removed, the shaft will be ribbed and converted into a two-track railroad tube, and extending from one side of the river to the other. In this manner, the coal will be transported from the Westmoreland County side of the stream to the Springdale plant, where it will be utilized and stored.

Hagerstown, Md. — Union Bridge Electric & Manufacturing Co. is planning for the extension of its lines to New Windsor, Taneytown, Legore, Key Mar, Middleburg, New Midway and other places in this district. At Legore, the company will connect with the system of the Hagerstown & Frederick Railway Co. Electric service is now being furnished to Union Bridge and Linwood. Clarence Easterday is president.

DATES AHEAD.

National Council of Lighting Fixture Manufacturers. Midsummer convention, Cleveland, Ohio, Aug. 5 and 6. Secretary-treasurer, Charles H. Hofrichter, 8410 Lake avenue, Cleveland, Ohio.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 19-21. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston Block, Seattle.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual Convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26, 1919. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Indian Head, Md.—The Bureau of Yards and Docks, Washington, has awarded a contract to Levering & Gerrigues, 553 West 23rd street, New York, for the building to house its proposed power plant at the Government works at this place.

Charleston, W. Va. — The State Board of Control has completed plans for the construction of a new one-story and basement power plant at the State Institution, Institute, W. Va. H. Russ Warne, Masonic Temple, Charleston, is architect.

Wierton, W. Va. — Wierton Steel Co. has awarded contracts to the Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., and the General Electric Co., Schenectady, N. Y., for electrical machinery and equipment for its proposed steel plant. The orders are said to aggregate $1,000,000.

Walnut Cove, N. C. — Piedmont Power Co., recently organized, is planning for the construction of a new electric transmission line to Winston-Salem. The company will furnish electric light and power service to Walnut Cove and Walkerstown.

Johnston, S. C. — Boyd utilities plant, F. M. Boyd owner, will install a 75-kv-a., 2300-volt alternator driven by internal combustion engine.

Lockhart, S. C.—Lockhart Power Co. will build a new one-story power plant, about 35x160 ft. The Hardaway Contracting Co., Columbus Ga., has received the contract for the building.

Orangeburg, S. C.—City will vote on issuance of $75,000 of bonds for enlarging the electric light plant and installing new machinery. E. Hawes, city engineer.

Cedartown, Ga.—Cedartown Cotton & Export Co. is building a $40,000 addition to its cotton products plant and will expend $125,000 for new machinery. An additional electric power plant is also to be erected.

Hayesville, Ga. — The Public Service Co. is in the market for electrical equipment for a hydroelectric plant and six transmission systems.

Springfield, Ga.—A municipal electric plant may be established.

Pensacola, Fla.—The contract for the construction and equipment of a 5000-ton drydock of the Crandall type has been let to the Aberthaw Construction Co. of Boston. The new drydock was designed by the Crandall Engineering Co. of East Boston, Mass., and consists of five floating pontoons, each 100x40 ft. and 10 ft. deep and costs approximately $450,000. Each of the five pontoons will be equipped with four submerged electric centrifugal pumps designed to empty the dock in one hour. The dock, which is being built for the Emergency Fleet Corp., will be used largely for government work when completed.

NORTH CENTRAL STATES.

Ashland, Oho.—Henry L. Doherty & Co. plan to install a 10,000-kw. turbine at the company's power station near Mansfield, Ohio.

Chillicothe, Ohio. — McVicker & Evans will erect a $150,000 paper mill Specifications include electric lighting.

Cleveland, Ohio. — Drew Electric & Manufacturing Co. has purchased a two-acre tract, on which it proposes to erect a plant at an estimated cost of $50,000 to include a machine shop and brass foundry. James H. Drew, president.

Lima, Ohio. — Ohio Electric Co. plans the erection of a new lighting and power plant. J. E. Dugan is general manager.

Lima, Ohio.—The question of issuing $100,000 bonds for municipal light plant will be submitted to voters. The plans as outlined in the report is for the city to install 600 lights of 400 cp., erecting its own poles and wires. With the equipment placed the city would then ask for bids on current from both the Ohio electric and water works plant.

Lima, Ohio—Lima Locomotive Works will spend $125,000 to build its own electrical plant as an aid to supply additional power if the Ohio Electric Co. does not proceed with its plans to double capacity of the local power plant. Address city clerk.

Oxford, Ohio.—Oxford will give up its municipal lighting plant after 30 years' operation. The town has received a bid from the Ohio Gas & Electric Co., Middletown. This company will erect a transmission line and will supply current under a franchise from the town. The proceeds of the sale of the light and power plant will be used for the purpose of rehabilitating and electrifying the municipal waterworks.

Indianapolis, Ind. — Springer McComas Grain Co. will erect concrete transfer elevator, capacity 25 cars, 177 ft. high, to cost $60,000, exclusive of ground. The company will install two grain dryers and one cleaner.

LaPorte, Ind. — Advance-Rumely Co. will erect new storage shed, 1000 x125 ft.; three two-story additions to the machine shop, one 20x187 ft., one 20x300 ft., and one 20x160 ft. The case-hardening and heat-testing departments will be enlarged by the erection of an addition, 30x40 ft. Improvements will also be made in the powerhouse.

Peru, Ind.—Modern Refrigerator Co. will erect two large buildings at its plant and will increase its capital stock from $25,000 to $100,000.

Shelbyville, Ind.—Universal Electric Co. has received a contract to wire Johnson county infirmary on its bid of $689.38, in order that an electric lighting plant can later be installed.

Arcola, Ill.—A company is being organized to establish a local light plant. Address Collins Brothers.

Charleston, Ill.—Coles County Telephone & Telegraph Co. will place all its wires underground at an estimated cost of $57,000.

Columbia, Ill.—An election to vote $16,000 bonds to extend and improve the municipal light plant carried.

Decatur, Ill.—The Illinois Traction System plans to erect a $2,000,000 power plant on the Sangamon river near Faries Park and the Wabash bridge on the way to Decatur. The plant will furnish power for Illinois Traction System interurbans and arrangements will be made for the transmission of power to Decatur. The present power plant at Cerro Gordo and Edwards street, Decatur, will be abandoned.

Dwight, Ill.—The mayor of this city and the members of the light and water committee of the Council have made a trip to Joliet, Ill., to study the lighting system of that city. The Public Service Co. of Northern Illinois has made a proposal to furnish lighting for Dwight and also for the use of electricity for pumping the city water supply.

Plato Center, Ill.—Board of education plans erection of township high school, 110 ft. x 100 ft. brick to cost $50,000.

Raritan, Ill.—A fund of $2500 has been raised by public subscription as bonus for the promotion of the enterprise for electric lights for Raritan. John K. Barry, president.

Springfield, Ill. — The mayor and city commissioners planned for a $400,000 bond issue to improve and complete the city electric light and power plant. That the light department will be amply able to take care of the payments is assured by commissioner Willis J. Spaulding.

Urbana, Ill.—The Urbana board of local improvements passed a resolution providing for the southwest ornamental lighting system, which provides for the new system of boulevard and West Race streets.

Urbana, Ill.—J. W. Swartz Electric Co. has secured the contract for the electrical work on the new building of the Transport Truck Co., Mount Pleasant, Mich.

Woodstock, Ill.—The City Council has contracted for a new unit for the municipal electric plant. It will be necessary to build an addition to the plant, estimated to cost $25,000.

Bay City, Mich.—Handy Brothers plan the extension within the next year or so of the Detroit, Bay City & Western Railway from Marine City into Detroit.

Verona, Mich.—Union Steam Pump Co. is erecting a machine shop, 150x 200 ft. The first unit of the proposed plant will cost about $500,000.

Chetek, Wis. — Agitation for a municipally owned light and power system has resulted in a proposition from the Chetek Light & Power Co. for sale of distribution system to the city for $9000. The question of purchasing the system and bonding the city will be submitted to voters next month.

Hortonville, Wis.—The village of Hortonville, which has been without street lighting since its gas plant was abandoned will be lighted with electricity furnished by the Wisconsin Traction Light, Heat & Power Co. The traction company will extend its lines to Dale, Medina and Sherwood. Nearly all farmers living along the lines have agreed to purchase current for lighting and power purposes.

Dubuque, Iowa—Dubuque Casket Co. will erect a new $30,000 factory building.

Waverly Iowa. — High school board of education plans the erection of a $200,000 high school.

St. Louis, Mo. — Bell Telephone Co., Broadway & Oliver streets, will build a $30,000 addition to plant.

Omaha, Neb.—Herring Motor Co., Des Moines, Iowa, will erect a plant for handling Fordson tractors and parts.

Wahoo, Neb.—Wahoo Produce Co., will erect a modern produce and cold storage plant, 66x120 ft., to cost $40,-000.

SOUTH CENTRAL STATES.

Louisville, Ky. — The Commercial Department of the Louisville Gas & Electric Co. during the week ended July 5, secured 45 new electric light and power customers with 17 kw. of lighting load and 382 hp. in motors. The net gain in business connected for the week was 54 customers with 55 kw. of lighting and 19 hp. in motors. Electric energy output for the week was 9.7% greater than for the corresponding week of 1918.

Texarkana, Ark.—Texarkana Telephone Co. will make extensive improvements. About $60,000 will be expended. Address the mayor.

Albany, Ala.—Alabama Power Co. has been granted a 30-year franchise by the City Council to take effect upon the completion of the new hydroelectric line from the Coosa river. It is estimated the line will be completed early in January. It will provide ample power for all industrial needs in the vicinity.

Montgomery, Ala.—Alabama-Georgia Syrup Co. will erect a $50,000 addition to plant. Conveyor systems will be used throughout all products being handled into and out of cars by the conveyors. Electric elevators and other modern devices for the expeditious handling of the immense business of this plant will be installed.

Union, Ala.—The City Council has arranged for the issuance of bonds for $10,000 to provide for improvements and extensions in the municipal electric plant.

New Orleans, La.—The erection of a central power house on the Mississippi river is planned by the U. S. Naval Station. The estimated cost is $120,000. Engineering Department of the U. S. Navy, Algiers Station, engineers.

Duncan, Miss.—The city will vote Aug. 5 on the issuance of $12,000 of bonds for extending electric light and waterworks systems. Address C. W. Erwin, mayor.

Natchez, Miss.—Improvements and additions are being made to the plant of the National Box Co., representing an investment of over $2,000,000. An electric plant is being installed and it is planned to operate all machinery electrically.

Ruleville, Miss.—The city will issue

$40,000 of electric light plant and street improvement bonds. R. S. Parker, city clerk.

Chelsea, Okla.—At a recent election bonds to the amount of $30,000 were authorized for a water and light plant.

Comanche, Okla. — Bonds to the amount of $35,000 have been voted for the water and electric plant. Address the mayor.

Enid, Okla.—City Ice Co. will improve its plant. J. C. Calhoun has been engaged to prepare plans for a complete new high-speed motor-driven machine with ice tanks of a capacity of 30 tons daily which will make the total capacity of this plant 40 tons per day. Necessary additions to be building will be commenced as soon as plans are completed.

Okemah, Okla. — An election will be held to vote on the question of issuing $50,000 extension and improvements of electric light plant. Address mayor.

Oklahoma City, Okla.—State Board of Affairs will erect a power house and laundry. N. T. Hardin, architect, Equity building, Muskogee, Okla.

Sapulpa, Okla. — Sapulpa Refining Co. has announced improvements to its local plant to cost in the neighborhood of $1,000,000. The Sapulpa Electric Co. has been asked to furnish current for operating 225 hp. in motors, more than one-half of which will operate continuously.

Burkburnett, Tex. — William L. Sonntag, of Wichita Falls, and associates are promoting the construction of an interurban electric railway between Burkburnett and that city. The preliminary arrangements in the matter of financing the project have been made. The line will be about 18 miles long, and will, it is expected, relieve the congestion of passenger traffic between two towns caused by the unprecedented oil development operations.

Corpus Christi, Tex.—Upon application of the Merchants Union Trust Co. of Philadelphia, Pa., the Federal court here has placed the Corpus Christi Railway & Light Co. in the hands of a receiver. C. U. Culberson of Houston was appointed receiver. The company owns the street railway system and electric light and power plant here. Improvements will be made to the property as soon as the sanction of the court for same is obtained.

Houston, Tex.—Houston Lighting & Power Co. will install additional generators and other equipment in its electric power station here and extend its power transmission system. The proposed improvements will cost about $500,000. S R. Bertron, Jr., is general manager.

Mexia, Tex.—The City Council is considering the erection of a municipal electric light and power plant to cost about $150,000.

San Antonio, Tex.—San Antonio Public Service Co. has adopted plans for installing a new steam turbine of a capacity of about 13,000 hp. at its power house on Conception avenue. The improvement will cost about $275,000.

Sherman, Tex.—The city proposes to build and equip an electric light and power plant to cost about $500,000.

Temple, Tex.—O. A. Ryfle of Houston, and associates who are promoting the construction of an interurban electric railway between Temple and Waco expect to have the surveys finished and right of way obtained so that construction may be started about Sept. 15. Committees of citizens have been appointed here and in towns on the route of the proposed line to assist in the preliminary plans for the project. The road will be about 35 miles long.

WESTERN STATES.

Missoula, Mont.—Improvements to cost $80,000 have been started by the Missoula Light & Water Co. at Bonner Dam.

Boise, Idaho. — Idaho Power Co. plans the erection of a transmission line from American Falls to Pocatello, a distance of 25 miles. The company is now installing a 3600-kv-a. generating unit at its lower Salmon hydroelectric plant.

Boise, Idaho. — Mackay Light & Power Co. will extend its lines down the Lost River to Arco.

Seattle, Wash.—Providing for the improvements and additions to the city's Lake Union steam power plant urged by J. D. Ross, superintendent of lighting, an ordinance appropriating $1,250,000 for the work was introduced into the City Council and referred to the utilities committee. The ordinance will be passed and work on the steam plant rushed.

Seattle, Wash. — Electric lighting fixtures estimated to cost $10,000 are to be installed in some of the present school buildings.

Marshfield, Ore.—An estimate of what it will cost to put the power plant at the Smith mill in good running order, in relation to both the part which supplies power for the Mountain States Power Co. and the part which furnishes power for the Smith mill, has been completed by the consulting engineer of the power company, to cost $60,000.

Portland, Ore. — Franks Laundry Co. will erect a $50,000 laundry at East 7th & Pine streets to be operated by electricity.

Porterville, Cal.—The City Council has under advisement plans for the establishment of a municipal electric light plant.

PROPOSALS

Lighting System.—Bids will be received until 8 p. m., July 28 by Black & Veatch, engineers, 507 Interstate building, Kansas City, Mo., for a lighting system at Osawatomie, Kans.

Centrifugal Pumps.—Bids will be received at the office of the director of public service, Delaware building, Akron, Ohio, until Aug. 1, for furnishing two horizontal centrifugal pumps, normal capacity 1000 gal. per minute against a total head of 80 ft. direct connected to electric motors. Specifications may be obtained from the Bureau of Waterworks Improvement, 102 East Mill street, Akron. G. G. Dixon, engineer; H. H. Frost, superintendent of waterworks.

Motor-Driven Triplex Pump.—Bids will be received at the office of the supervising architect, Treasury Department, Washington, D. C., until Aug. 8, for a new motor-driven triplex pump, etc., in the United States post office and custom house at Cairo, Ill.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number given.]

Electrical Machinery (30,004).—The agency for the sale of building materials, hardware, domestic and general, motor accessories, and electrical machinery and fittings is desired by a man in England. References.

Electrical Apparatus (29,964).—A firm in Australia wishes to get in communication with American exporters of electrical wires, cables, conduits, machinery, lamps, fittings, and glassware, metals and metal products, machinery for all industrial purposes, hardware, plate glass, sheet glass, lumber, oils, chemicals, paper, textiles, canned goods, automobiles and accessories.

Electrical Aerial Trolley System (29,966).—An electrical aerial trolley system to carry passengers between mountain top is desired by a company in Portugal. Quotations should be given c. i. f. Portuguese port. Payment, credit in New York. Correspondence may be in English. References.

Electric Motors (29,967).—A company in India desires to purchase complete paint manufacturing machinery with output of 10 tons per day, a portion of which will be enamels, oxides and ochres. Electric motors should be supplied with large machines. Quotations should be given c. i. f. Indian port. Payment in the United States against documents. References.

INCORPORATIONS

New York, N. Y.—Metricappliance Corp. Capital, $20,000. To manufacture electric meters. Incorporators: A. W. Franklin, M. B. and D. B. Kassel, 47 West 112th street.

New York, N. Y.—Universal Condenser. Capital, $100,000. To manufacture condensors and kindred equipment. Incorporators: P. G. Chichester, Brooklyn; E. Nolan, and D. T. Howell, 945 East 180th street, New York.

Personal

C. H. Howell Elected President Ohio Electric Light Association—V. R. Lansingh President of Lunken Window Co.

W. S. Robertson, who has been connected with the Nebraska Power Co. for about two years, has been appointed assistant general manager in charge of operation. He will have charge of all the operating departments of the company.

William Petschel, electrical engineer and storage battery expert, formerly president and manager of the Atlas Electric Storage Battery Co., Greenville, Mich., is now general manager and vice-president of the Vulcan Storage Battery Co., Brazil, Ind.

John Gillespie, formerly affiliated with the steel casting department of the Midvale Steel & Ordnance Corp., has accepted the appointment of general superintendent of the Philadelphia Electric Steel Corp., Conshohocken, Pa., succeeding Arthur S. Breithaupt.

Raymond G. Sherman, superintendent of the Deerfield River Power Co., has been appointed superintendent of the Connecticut River Power Co. of New Hampshire, Brattleboro, Vt., both of which concerns are under the management of the New England Power Co., with headquarters at Worcester, Mass.

Terence Farley, New York, has been appointed general counsel to the Public Service Commission, New York, by Commissioner Lewis Nixon, to succeed Godfrey Goldmark, recently resigned. Mr. Farley has been an assistant corporation counsel for 27 years, and for the last 12 years has been at the head of the Appeal Bureau of that office.

George W. Hubley, who recently terminated his office as administrative engineer and chief of conservation of the United States Fuel Administration of Kentucky, has opened an office in Louisville as a consulting and advisory engineer and also to furnish service as a power plant specialist. Mr. Hubley was previously general manager of the Badenhausen Co. of Philadelphia and New York City, prior to which time he was general manager and chief engineer of the Merchants' Heat & Light Co. of Indianapolis, Ind.

H. M. Turner has been made assistant professor of electrical engineering in the Sheffield Scientific School of Yale University. Professor Turner was graduated from the University of Illinois and for several years has been in the Electrical Engineering Department of the University of Minnesota. He went to Yale last fall as assistant professor of radio and advanced electrophysics and directed the field radio work of the Signal Corps Training School for officer candidates. Since its disbanding his work has been in the Electrical Engineering Department, in which department he is now continued.

Van Rensselaer Lansingh, formerly general manager and chief engineer of the Holophane Works of the General Electric Co., Cleveland, and later manager of the Holophane Sales Department of the National Lamp Works of General Electric Co., Nela Park, Cleveland, has been elected president of The Lunken Window Co., Cincinnati, Ohio. This company manufactures a unit window consisting of window frame, disappearing sash and fly-screens. The upper and lower sash telescope into a window box above the usual window opening, making it possible to secure maximum ventilation from the entire window opening at the same time screening from top to bottom.

Van Rensselaer Lansingh.

Mr. Lansingh entered the University of Chicago in 1892, graduated January, 1896. From February, 1896, to June, 1898, he attended the Massachusetts Institute of Technology, receiving the degree of Bachelor of Science in electrical engineering. In February, 1899, he entered the testing department of the Western Electric Co. with whom he remained until July, 1900, when he formed the V. R. Lansingh Co. in Chicago, sales agent for Holophane reflectors. In September, 1904, he was appointed general manager and chief engineer of the Holophane Works of General Electric Co. and in March, 1914, became manager of the Holophane Sales Department of the National Lamp Works.

In August, 1914, Mr. Lansingh resigned that position to start in Chicago The Hardware Buyers Association, which later became the By-Lo Stores Co., operating a chain of hardware stores at Muncie, Frankfort and Anderson, Ind. The advent of our entering into the world war prevented the expansion of this chain and consequently, in March, 1917, he entered as a volunteer in the Council of National Defense at Washington, D. C., serving under Dr. Hollis Godfrey, one of the advisories of this Council. He continued work along different engineering lines until June, 1917, when he sailed for France to represent the Massachusetts Institute of Technology, which was later consolidated with the American Universities Union in Europe with headquarters in Paris and with branches in England and Rome. For a year he served as a director of the Technology Bureau in the Union and also as business manager and assistant director of the organization, whose purpose it was to serve college men and friends in service abroad and to promote closer relationship between American and foreign universities. In July, 1918, he returned to the States and in October was placed by the Government in the Metz Plant at Waltham, Mass., as works manager in the plant manufacturing airplanes for the Government. He continued in this capacity until April, 1919, and in June became president of The Lunken Window Co., Cincinnati, Ohio. Mr. Lansingh has been prominent in the activities of the Illuminating Engineering Society, having been its general secretary in 1906 and president for the term ending in December, 1912. He has also served the society in other offices and on committees, and has been closely identified with the advancement of scientific principles concerning the use of reflectors of light sources. In collaboration with J. R. Cravath he wrote a book, "Practical Illumination," which has had a very wide circulation and is not only in the library of every man interested in lighting, but has been used extensively as a text book in many educational institutions.

Franklin T. Griffith, president of the Portland Railway, Light & Power Co., Portland, Ore., and C. M. Clark, chairman of the board of directors of that company, of Philadelphia, recently made a 5-days' trip on horseback over the headwater-region of the Clackamas river, on the western slope of the Cascade mountains. Their trip was to look over sites for possible hydroelectric development. This is undoubtedly in anticipation of greatly increasing power demands within the next few years.

E. H. Waddington, president of the St. Louis Electrical Board of Trade and western district manager of the Pole and Line Material Department, Western Electric Co., met with a serious accident recently while on a tour of inspection in the West. While engaged in the work of inspection at the company's pole yards at Spirit Lake, Idaho, he was caught in a slide of poles and had his left leg broken below the knee. An X-ray revealed the injury to be two fractures near the joint. He will be confined to his home for several weeks. Mr. Waddington has been actively connected with the St. Louis Jovian League for a number of years and was a member of the committee that formulated the plan for its reorganization into the St. Louis Electrical Board of Trade. He has a host of friends who sympathize deeply with him in his misfortune.

ARTHUR E. ANDERSON, formerly chief engineer of the Intermountain Railway, Light & Power Co., Denver, Colo., has assumed the position of general superintendent of the Grand Junction Electric, Gas & Manufacturing Co., and the Grand River Valley Railway Co., Grand Junction, Colo.

LANDERGREN ARMSTRONG, for the last three years publicity manager for the Crouse-Hinds Co., Syracuse, N. Y., has associated himself in a similar capacity with the Brown-Lipe Gear Co.. of the same city, the pioneer manufacturer of transmissions, clutches and control sets for pleasure cars and auto trucks. Mr. Armstrong was a member of the Crouse-Hinds organization for ten years, during the first seven years of which he served as assistant publicity manager. Prior to that connection, he occupied an editorial position with the New York News Bureau of New York City.

B. F. TUCKER, manager of operations for the Central Illinois Public Service Co., with headquarters at Mattoon, Ill., has resigned that position to become manager of a 1225-acre farm near Peoria, owned by himself and two associates. Mr. Tucker was one of the owners of the electric lighting plant at Virden, Ill., until it was taken over by the Central Illinois Public Service Co. He then entered the service of this company at Taylorville, Ill., taking the position of district superintendent. He was later transferred to Mattoon, where he became assistant general superintendent and in February, 1915, was appointed general superintendent and in January, 1919, became manager of operations. Mr. Tucker has also been deeply interested in agricultural operations for a number of years and will take up farming on a large scale. He will apply mechanical power as far as possible to farm operations.

DR. V. BUSH, engineer of the American Radio & Research Co., has been appointed associate professor of Electrical Engineering at the Massachusetts Institute of Technology. Dr. Bush is a graduate of the Electrical Engineering course of Tufts College and received an M. S. degree from that college in 1914. He received the degree of Doctor of Engineering from the Massachusetts Institute of Technology in 1916. After graduating from Tufts he had been an instructor on its staff with a notable record as a teacher and was later made an assistant professor. During the course of scientific researches in the war, Dr. Bush was associated with the New London researches of the United States Navy for the detection of submarines and did distinguished service in that work. The doctor's thesis which he presented at the Massachusetts Institute of Technology will be remembered by electrical engineers from a paper read before the midwinter convention of the A. I. E. E. in February, 1917, entitled "Oscillating Current Circuits by the Method of Generalized Angular Velocities," in which a discussion is given of the "threshhold impedances." In his new position, Dr. Bush will take up a portion of the instruction to undergraduate students heretofore given by Professor Wickenden, who recently resigned to go permanently into the service of the Western Electric Co. In addition Dr. Bush will give a course of advanced lectures to postgraduate students and devote the remainder of his time to research.

C. H. HOWELL, newly elected president of the Ohio Electric Light Association, is vice-president of The Ohio Service Co., Coshocton, Ohio. He was graduated from Richmond College, Richmond, Va., in June, 1905, with the degree of Bachelor of Science, and immediately thereafter accepted a position as car barn foreman with the Newport News & Old Town Street Railway Co. at Hampton, Va. In January, 1906, he entered the student course of the General Electric Co. at Lynn, Mass., and coincident with this work in 1906-1907 took post graduate work in thermodynamics and electrical engineering at the Massachusetts Institute of Technology. In 1908 Mr. Howell entered the student course of the General Electric Co. at Schenectady, N. Y., and in 1909 entered sales work as commercial engineer in the power and mining and small motor department of the General Electric Co., Pittsburgh. He pursued this work until August, 1912, when he accepted the position of manager of the Coshocton Light & Heating Co., Coshocton, Ohio. In January, 1913, jointly with this position, he took the managership of the New Midland Power & Traction Co., Cambridge, Ohio, and in May of the same year took a similar position with the County Electric Co. at New Philadelphia and Dennison, Ohio, and the Twin City Traction Co. at Dennison, Ohio, and the Tuscarawas County Light, Heat & Power Co., New Philadelphia. Also during the year 1913 he was appointed manager of the Lafayette Light & Power Co., Strasburg, Ohio. All of these companies, including the Strasburg Electric Co., Strasburg, the Newcomerstown Light, Heat & Power Co., Newcomerstown, were later merged into a single corporation, which is now known as The Ohio Service Co.

C. H. Howell.

Under Mr. Howell's directorship the company since 1914 has constructed over 111 miles of 33,000-volt transmission lines, connecting all the above towns, some 21 miles of 13,000-volt power feeders, and two new power houses. The company is now operating in 26 different communities scattered over four counties; two railway systems; two central district heating systems and two hydroelectric plants. Since 1914 the revenue of The Ohio Service Co. has grown more than 100% and the number of customers connected to its lines since the beginning of 1916 has increased 77%. Mr. Howell was one of the first among those who appreciated the possibilities of selling utility stock to customers and residents in the territory served by the utility. Today he is reaping the benefit of this for his policy has been prosecuted most successfully. He is a member of the American Institute of Electrical Engineers, American Electrochemical Society, the Boards of Trade of Coshocton, Cambridge, Dennison, Uhrichsville, New Philadelphia and Dover, and is a director in the Coshocton Board of Trade, a Rotarian at Coshocton, and for a number of years has been a member of the executive committee of the Ohio Electric Light Association.

G. F. WITTIG has been appointed assistant professor of Electrical Engineering in the Sheffield Scientific School of Yale University. He has been at Yale during the past year, first in connection with the Signal Corps Training School for officer candidates and after its disbanding has been a member of the Physics Department. Professor Wittig received his degree at Columbia. He was associated for a time with the Westinghouse, Church, Kerr Co. and assisted A. V. Abbot in the revision of his book on "Electrical Transmission of Energy." He was for several years head of the Department of Electrical Engineering and Physics at the University of Alabama and was later assistant professor of Electrical Engineering at the University of Pennsylvania. During last summer he was associated with the Radio Division of the Bureau of Standards and was co-author of the book on radio written by the Bureau of Standards which has appeared as Pamphlet No. 40. In the summer of 1917 he was division engineer in the construction of Camp McClellan.

OBITUARY.

OSCAR OTTO, general superintendent of the South Philadelphia Machine Works of the Westinghouse Electric & Manufacturing Co., died at his home on June 30 as a result of fatal injuries received in an automobile accident on the previous Friday morning, while driving his car up a steep grade near Westgrove, Pa., where he met an army truck-train which was descending the hill. One of the trucks skidded, sideswiped his car and completely demolished it. Mr. Otto was born in Manitowoc, Wis., on Jan. 2, 1858. After finishing his apprenticeship course as a machinist in the Manitowoc shops of the Chicago & Northwestern Railway, and later serving several years at various places in the state of Wisconsin, he accepted a position with the Northern Pacific Railroad Co. at Tacoma, Wash., going from there to the Oregon Short Line at Salt Lake City. In 1898 he returned to the Chicago & Northwestern Railroad as superintendent of its Chicago shops, continuing in this position until June, 1909, when he was appointed superintendent of the Westinghouse Machine Works at East Pittsburgh. When the Westinghouse company opened its new plant at Essington Mr. Otto supervised the installation of the machinery, and later, in February, 1918, he was permanently transferred to the new works, where he remained until his death. The deceased is survived by his widow, a daughter and three brothers.

Financial News

Mexican International Corporation Formed.

Interest in Mexico as a field for future development and financing is evidenced in the announcement made July 15 of the organization of the Mexican International Corp. by a group which includes officers of important banking and business houses.

This corporation has been organized under the laws of the State of Delaware and officers will be maintained both in New York City and in Mexico City. Its purposes are set forth as: (1) the investigation of existing enterprises to determine their physical and financial condition, management and future prospects and the development therefrom of plans for refinancing and extension which will procure for the corporation an interest in the enterprise; (2) the investigation of proposed enterprises to determine their merit, probable cost and future prospects, and the development therefrom of plans for the financing, construction, management and ultimate disposition of the enterprise; (3) the investment in, underwriting and organization of underwriting syndicates for the development and operation of such enterprises in Mexico as may be approved by the corporation. Should developments indicate the necessity therefor, the corporation will establish a service department to furnish information and service of a character in keeping with its purposes.

The officers of the corporation will be: President, Thomas H. Gillespie, president of T. A. Gillespie Co.; vice-presidents, George J. McCarty, president of the Mercantile Banking Co., Ltd., of Mexico City, and H. S. Brown. Mr. McCarty will be in charge of the corporation's offices and organization in Mexico City.

Mr. Brown will be in charge of the corporation's offices and organization in New York City. He has had 17 years' experience in financial work in New York City and has spent considerable time in Mexico. During the war he was chief of the Finance Division of the Bureau of Aircraft Production in Washington and after the signing of the armistice became an assistant to the United States Liquidation Commission in Paris.

The capital stock of the corporation will be divided into two classes. There will be 10,000 shares of preferred 7% cumulative stock of the par value of $100 and 25,000 shares of common stock with a par value of $5. Both classes of the stock will be subscribed for in cash at par, 25% of the subscription being immediately payable and the remaining 75% being payable in whole or in part at such time as the directors may determine. Subscribers to the preferred stock will have the right to subscribe to an equal number of shares of the common stock.

In announcing the organization of the corporation, Harvey D. Gibson and Grayson M. P. Murphy, the syndicate managers, made the following statement:

"For the United States the course of Mexican affairs is particularly vital and if properly followed should offer unusual opportunities. Not only is Mexico so located as to afford a natural field for investment and development by our people, but she has unexploited natural resources, the mere scratching of which would provide the means to clear off all her national debt and place her on a sound financial basis. With a soil capable of producing all the cereal crops and 90% of all the known fruits of the world, with vast tracts of timber, including many varieties of precious hardwoods and dyewoods, with a wide range of climate, with every known mineral, and with oil fields which exported more than 63,000,000 barrels in 1918, Mexico needs only a return to normal conditions and the introduction of modern methods and modern machinery to bring her quickly into the front rank of the producing world."

Duquesne Light Bond Issue.

The Duquesne Light Co. has sold to a syndicate of New York bankers, comprising Harris, Forbes & Co., Ladenburg, Thalmann & Co., and Lee, Higginson & Co., $25,000,000 first mortgage, 30-year 6% gold bonds to be sold at par. The sale of these bonds will assure the erection without delay of the large electric power plant at Cheswick, which will guarantee all power needs of the Pittsburgh district for the future.

The company owns and controls in large part, directly operates properties, conducting the entire central station, electric light and power company business in Pittsburgh and throughout the major portions of Allegheny and Beaver counties in Pennsylvania. It controls a single interconnecting system which serves a total estimated population of 1,100,000 people. The net earnings of the company for the year ended April 30 were over two and one-half times the fixed charges including interest on the present bonds.

Dallas Power & Light Bond Issue.

An offering of $4,500,000 first mortgage 6% gold bonds is being made by Lee, Higginson & Co., and the Harris Trust and Savings Bank, Chicago, at 100 and interest, yielding 6%. They are dated July 1, 1919, and become due July 1, 1949, principal and interest being payable in Boston or New York. The bonds will be secured by a direct first mortgage on all properties and franchises of the company. The company will have no other funded debt upon completion of the present financing. The Dallas Power & Light Co. acquired by purchase on Sept. 29, 1917, all the properties of the Dallas Electric Light & Power Co., which has been conducting an electric light and power business in Dallas, Texas, for 16 years. The company does substantially all the electric light and power business in Dallas. The new franchise approved by popular vote of the city on April 3, 1917, established a definite "property value" now amounting to about $6,200,000, against which, the mortgage provides, not exceeding $5,000,000 of these bonds may be issued, including the $4,500,000 now offered. Under the new franchise the company is now authorized to reserve out of net earnings, as a first charge, 9% on the "property value." On $6,200,000, this 9% amounts to $558,000, or more than twice the $270,000 annual interest on these $4,500,000 first mortgage bonds.

Indiana Utility Commission Orders.

The Public Service Commission of Indiana, in a recent conference at which a number of orders were passed, authorized the Interstate Public Service Co. to buy the Indianapolis & Louisville Traction Co. This gives the Interstate Co. a direct line by actual ownership or leases from Indianapolis to Louisville.

The Interstate company acquires the I. & L. by paying $330,000 for the capital stock of the company and by assuming the $846,300 bonded indebtedness. The I. & L. property, consisting of 41 miles of interurban track between Seymour and Sellersburg, figured in the deal at $28,700 a mile or a total of $1,176,300, which is covered by the purchase price and the bonded indebtedness. The commission authorized the Interstate company to issue 31,200 bonds to retire a part of the $846,000 bonded indebtedness.

The commission authorized the Northern Indiana Gas & Electric Co. to issue $1,906,000 10-year, 7% notes at par. The notes are designated to take up $955,300 demand 6% notes issued by the company and to take up $950,855 of an open 8½% account with its holding company, the United Gas & Improvement Co. The new note issue will reduce the fixed charges of the company $4720 annually.

The commission directed the Brazil Gas Co. and the Terre Haute, Indianapolis & Eastern Traction Co. to make physical changes in their Brazil properties to prevent electrolysis of the gas company's mains because of escaping current from the traction company wires.

American Interests Ask Concessions in Mexico.

Applications filed by American and other foreign investment interests for concessions for the construction of electric and steam railroads and various other kind of industrial enterprises are now pending with the Department of Communication and Public Works of the Mexican government. It is indicated by the attitude of the Carranza administration toward outside capital that these applications may all be rejected. The government has already adopted the policy of not granting any new concessions for the construction of additional lines of steam railroad. It has announced its intention of doing on its own account whatever railroad building may be deemed necessary, adding such lines to the National Railways of Mexico. Recently application was filed with the Department of Communications and Public Works for a concession to construct an electric interurban railway through the oil fields of the Gulf Coast region, connecting Tampico and Tuxpan. The proposed line would be about 120 miles long. No action has as yet been taken upon this application.

Dividends.

Carolina Power & Light Co. has declared a quarterly dividend of 1% on common stock, payable Aug. 1 to stock of record July 15.

Directors of the Connecticut Railway & Lighting Co. have declared a quarterly dividend of 1⅛% on common and preferred stock, both payable Aug. 15 to stockholders of record Aug. 1.

Duquesne Light Co. has declared a quarterly dividend of 1¾% on preferred stock, payable Aug. 1 to stock of record July 1.

Railway & Light Securities Co. has declared dividends of 3% on both common and preferred stock, both payable Aug. 1 to stock of record July 15.

The board of directors of the Texas Electric Railway Co. has declared a quarterly dividend of 1¾% on second preferred stock, payable Aug. 1 to stock of record June 30.

West Penn Power Co. has declared a quarterly dividend of 1¾% on preferred stock, payable Aug. 1 to stockholders of record July 21.

West Penn Traction & Water Power Co. has declared a quarterly dividend on preferred stock of 1½%, payable Aug. 15 to stock of record Aug. 1.

Commonwealth Edison Co. has declared a quarterly dividend of 2%, payable Aug. 1 to stock of record July 15.

Edison Electric Illuminating Co. of Boston has declared a quarterly dividend of 3%, payable Aug. 1 to stock of record July 15.

Edison Electric Illuminating Co. of Brockton has declared a quarterly dividend of 2%, payable Aug. 1 to stockholders of record July 21.

Electric Securities Co. has declared a dividend of 1¼% on preferred stock, payable Aug. 1 to stock of record July 22.

Electric Bond & Share Co. has declared a quarterly dividend on preferred stock of 1½%, payable Aug. 1 to stockholders of record July 16.

Illuminating & Power Securities Co. has declared a quarterly dividend of 1¾% on preferred stock, payable Aug. 15 to stock of record July 31.

Lowell Electric Light Co. has declared a quarterly dividend of 2½%, payable Aug. 1 to stock of record July 21.

Westinghouse Electric Export Co., 165 Broadway, has filed notice of an increase in its capital stock from $100,000 to $5,000,000, and a change in its corporate name to the Westinghouse International Co.

First Mill Built North of Dubuque, Iowa—Now Housing the Electric Power Plant of Schmidt Brothers, Elkader, Iowa.

Utilizing Old Mills for Hydroelectric Power Plants

Famous Flour Mills in Northeastern Iowa Converted to Electric Service—Transmission Lines Supplying Extensive Farming Districts Are Fed from the Remodeled Mills—Features of the Modern Service

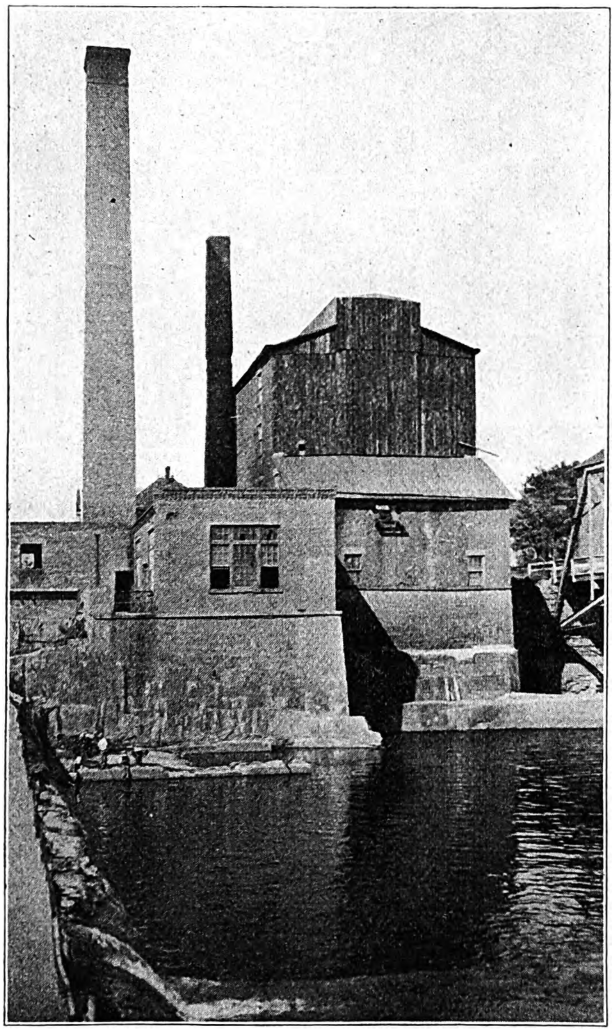
By F. L. CLARK

AN INTERESTING electrical development in Iowa is the utilization of old flour mills and mill sites in the northeastern part of the state as hydroelectric plants.

Most of Iowa is level or slightly rolling prairie, but the topography of the four most northeastern counties is quite different. The Switzerland of Iowa it is called. Many swift streams and rivers have cut deep channels in the bluffs and the gentle contour of the land breaks into rocks and crags, forested hills and fern-carpeted dells. In early days before the railroads had built west of the Mississippi, these swift streams played an important part in the settlement of northern Iowa and southern Minnesota. Wheat was the great crop of the pioneers but with no railroads they were without a market and the crop was worthless in the beginning. But the rocky-banked, swift running streams solved the situation. Mill sites were found everywhere and mills, big and little, sprang up all over the northeastern corner of the state. In just one of the four northeastern counties there were 58 at one time—saw mills and flour mills together. Most of these were small affairs serving only local uses and disappeared with the decline of wheat growing. A few of the larger ones continued doing business for a good many years.

Of this number the two largest and most famous were the mills built on the Turkey River by Messrs. Thompson, Sage and Davis at Elkader and Clermont. The Elkader mill was built 75 years ago and at the time was the largest mill west of the Mississippi in the Northwest. Some years later the Clermont mill was erected and was a great success. The proprietor of this mill, William Larrabee, later was twice governor of Iowa. Farmers came from as far as 150 miles to have their wheat ground at these mills.

Both mills were built out of rough rock dug from the hillsides of the Turkey River. They were well built to stand the test of time. After years of usefulness as flour mills, they have recently taken a new lease on life and entered upon a career of a new character. The old buildings, apparently good for a hundred years, are now housing electric power plants and on the site of the old log dams which used to hold the water to turn the big wooden water wheels of the mills, handsome structures of concrete and steel have been erected to generate electricity. The original purpose of helpfulness to the farmer is not lost, for electric light and power is supplied to many of the same farms which used to send wheat to the mills in former years.



Power Plant of C. C. Miller & Sons at Claremont, Iowa, Formerly Owned by Governor Larrabee.

The company at Clermont is composed of Chris Miller & Sons, who have recently incorporated with the name of the Northeastern Iowa Power Co. The Elkader power plant is owned by the Schmidt Brothers. The transmission lines of the two companies serve adjoining territory in northeastern Iowa. The Schmidt company supplies Guttenberg, Elkader, Garnavillo and a score of smaller towns and villages. The Northeastern Iowa Power Co. has over 200 miles of transmission lines and serves West Union, Fayette, Clermont, Elgin, Fort Atkinson, Lawler, Edgewood, Hawkeye and lesser towns in the same territory. In addition to their power plant at Clermont, the Millers now have a plant at Waucoma and have converted another old mill on the Volga River into a second subsidiary plant. The Schmidt Brothers have purchased a second power site on the Turkey River and expect soon to expand their system. The two power plants are supplying power to many creameries, cheese factories and small manufacturing concerns of various kinds, such as saw mill, planing mill, overall factory, excelsior mill, sash and door factory and ice plant. Several rural consolidated schools are provided with light and motor service and have electric stoves in their domestic science departments. The $100,000 school at Clermont, William Larrabee's bequest to the home village, is lighted and electrically equipped from his old mill and mill site.

The principal expansion of the Turkey River power companies at present is in the way of farmers' lines. A network of these is spreading throughout the region, accomplishing much in the improvement of country life.

MOVING FREIGHT TONNAGE ELECTRICALLY IN LARGE UNITS.

Pair of Pennsylvania Railroad's New 250-ton Electric Locomotives Can Haul 6300-ton Train Up Grade at 20 Miles an Hour.

The ability to increase track capacity for the rapid expedition of heavy freight trains is fast becoming a difficult problem, owing to the tremendous increase in train tonnages to be moved as a unit. In other words, the problem before many steam-railroad operators is how to increase the physical capacity of a certain heavy-tonnage division without prohibitive expense. At the same time, after such an expenditure in correcting alinement, grade reductions and other operating difficulties, there still remains the problem of operation, namely, hauling without delay the tonnage offered for transit.

With the introduction of the large type FF1, 250-ton electric locomotive of the Pennsylvania Railroad recently exhibited at the Master Mechanics' and Master Car Builders' convention held at Atlantic City, there dawns a new era in the possibility of moving heavy tonnage in large units over steep grades. Here is motive power equipment of tremendous capacity having a maximum accelerating power of 7600 hp., with a sustained capacity of 4800 hp. for one hour. With two of these big electric engines a 6300-ton train can easily be handled up long grades at constant speed as, for instance, on a 25-mile 1% grade, such a train could be moved at 20.6 miles per hour. Thus there exists equipment for hauling traffic in much larger units and with the rapid movement of such large quantities of freight the division can rapidly become cleared and made ready to handle considerable additional tonnage.

The Pennsylvania type FF1 locomotive was built within existing operating limits reaching the maximum starting draw-bar pull which average freight cars will permit; the maximum tractive effort consistent with the wheel arrangement used; the maximum weight on drivers; the maximum horsepower per unit weight and the maximum speed considered desirable with the contemplated operation.

This locomotive was designed under the general direction of J. T. Wallis, general superintendent of motive power, Pennsylvania Railroad, together with B. G. Lamme, chief engineer, Westinghouse Electric & Manufacturing Co.

Central-Station Rates in Theory and Practice

Fourth Article—Responsibility for Peak Load—Apportioning the Demand Cost Among the Customers—Theoretical Division of Demand Charges Based on Load Curves

By H. E. EISENMENGER

This is the fourth article of this series, which began in the issue of July 12, and will appear weekly practically throughout the present volume. A general outline of the entire series was published in the issue of July 5. In the first three articles the author first discussed costs in general, then the cost of electric service in particular, dividing the latter into three elements—energy, demand and consumer costs. The present article continues the consideration of demand costs and shows how they are apportioned among different classes of customers and among individual customers. This discussion will continue through several more articles. After a knowledge of costs has been obtained, the price of electric service (rates), which depends largely on the costs, will be taken up.

PART I—THE COST OF ELECTRIC SERVICE—Continued.

II—A. The Three Elements of Cost.

B. THE APPORTIONMENT OF THE DEMAND COST BETWEEN THE CUSTOMERS.

1. *The Peak Responsibility.*

SECTION 26. The most important object of the computation of the cost of service is the ultimate apportionment of that cost between the consumers, that is to say, the determination of the share of the cost which is caused either by an individual consumer or by a certain group of consumers, for instance by the power consumers. Unless we go into theoretical details of little practical importance, this apportionment is simple and easy in case of the energy cost, where it has to be made simply according to the number of kilowatt-hours, but it is less simple, theoretically as well as practically, in case of the demand cost.

Since the total demand cost is proportional to the central station's peak load, the demand of a group of consumers or of an individual consumer is apparently proportional to the share which is contributed by that group or individual to the peak load of the central station.

Now, the peak load of the central station is built up of the sum of the amounts of power required by the individual consumers at the central station's peak-load time, enhanced by the line and transformer losses and the power demand of the central station for its own operating purposes. If a consumer is using 100 kw. at the central station's peak-load time, the central station has to keep 100 kw. (plus a percentage enhancement for the above-named losses, etc.) of capacity ready for his use and for *his* use only, regardless of whether he is using these 100 kw. during the peak-load hours only or for 365 24-hour days a year[1]. If the total capacity of the central station and lines, etc., is, for instance, 10,000 kw., the demand cost of that consumer will be 1% of the total demand cost of the central station; if he uses 200 kw. at the central station's peak-load time, his demand cost will be 2%, and so forth; in short, it will be proportional to the capacity used by him at the central station's peak-load time.

[1]This statement will have to be revised and slightly modified in the following paragraphs (see also Insert VI), but for the purpose of a first introduction it is of sufficient accuracy.

The demand of a customer at the time of the central station's annual peak load is therefore a very important factor for the theory of the demand cost. It defines the measure in which the consumer is responsible for the building up of the central station's peak and it has therefore very properly been called the *"Peak Responsibility."* This very descriptive name will be used hereinafter for the consumer's demand at the central station's peak-load time. Thus, if the lower curve in Fig. 1 would represent the load curve of an individual consumer or the aggregate load curve of a certain group of consumers, and if the upper curve would be the total load curve of the

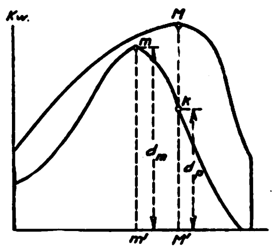


Fig. 1.

central station, $d_p = M'k$ would be the "Peak Responsibility" of that consumer or group of consumers.

2. *The Theoretically Exact Basis.*

27. If we give further thought to the problem of the demand cost, we will soon find that it is not the peak responsibility alone which has a bearing on the demand cost of a consumer. The following hypothetical example will explain the general idea.

Assume a 1000-kw. central station to have two consumers or classes of service only: *"A"* using 500 kw. from 5 to 6 o'clock every afternoon and nothing outside of that time, and *"B"* using 500 kw. for 24 hours every day. The peak load of the central station occurs then during the hour from 5 to 6 p. m., and the peak responsibility of each one of the two consumers is 500 kw. If we were to judge by the peak responsibility alone, the central station's demand charges would have to be equally divided between the two consumers. It is clear, however, that the central station could take on new consumers without increasing its total capacity and demand cost, if these new consumers never exceed an aggregate demand of 500 kw. and if all their demand occurs outside of the hour from 5 to 6 o'clock. They are then making use, so to speak, of the 500 kw. which are "charged" to *A*. (It should be remembered that we are dealing here with the cost and not with the price, so that the term "charge" is here not used in the meaning of "price-making" but only in the book-keeping sense of apportioning the cost.) The shape of consumer *B*'s load curve does not permit any other consumer to use the portion of the central station's peak load for which *B* is "charged," because, according to the assumption, *B* never releases that portion for the use of others. It seems logical, therefore, that *B* should be "charged" for a larger portion of the demand cost than *A*, although they both have the same peak responsibility.

We will always find corresponding conditions wherever there is a diversity between the consumers[2], in other words, where the load curve of the respective central station's load curve is more or less a sharp point, the peak responsibility of a consumer is of greater relative influence on his demand cost than if the central station's load curve has a well rounded-off top which extends over a comparatively long period.*

Insert VI—Appendix to Section 28.

Apportionment of the Demand Cost to the Individual Consumers, Considering the Shapes of the Load Curves (Diversity-Factor).

CONTAINING ELEMENTARY MATHEMATICS.

It is easily shown that the "Peak Responsibility"[1] is not the theoretically correct measure for the demand charge of a certain consumer.

Starting with the assumption of the simple case that the central station has only two consumers *A* and *B* with a plain rectangular load curve each, as per Fig. A, it might be believed at first sight that consumer *A* has to carry the demand charges alone, whereas *B* is using only a part of the central-station capacity which has to exist anyway in order to serve *A*. The possibility of serving *B* will therefore be only a by-product.[2]

That this way of reasoning is wrong can be easily seen if we assume that *B* is increasing his demand gradually up to 800, 900, 990 and 999 kw. As soon as he has gotten so far, the slightest increase of his maximum demand would throw the whole demand charges[3] onto his shoulders and *A* would just as suddenly be entirely relieved of demand charges, if the above way of reckoning were correct. If *B*,

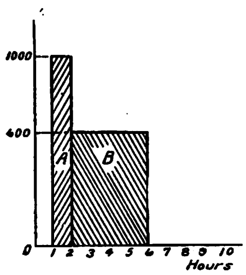

Fig. A.

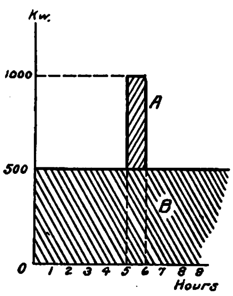

Fig. B.

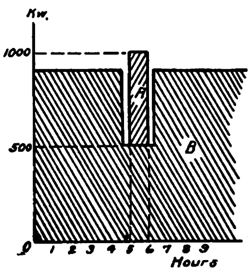

Fig. C.

consumer is not entirely similar in shape to the central station's load curve.

28. The solution of the problem to find the real value of the consumer's demand cost requires a rather complicated, though by no means difficult, mathematical analysis, which is given in Insert VI, together with the resulting full solution of the problem. A synopsis of the results of this mathematical analysis is contained near the close of Insert VI. Condensing these results still more and expressing them in non-mathematical terms with a corresponding loss of preciseness, we can say that a consumer's demand cost is not determined exclusively by his load at the central station's peak-load time but also by the amount of his load at such times when the central station has to carry a load which is nearly as large as the peak. The demand cost of a consumer is influenced by the amounts of his load *at every single moment of time,* but the influence decreases steadily according to a certain law as we proceed from the element of time at which the central station's load is a maximum (peak load) to such elements at which the central station's load is smaller. The influence of the consumer's momentary load at such moments of time when the central station's load is near its maximum is paramount, whereas at such times when the central station's load is not a large percentage of the peak load that influence becomes insignificant or practically imperceptible.

29. It follows from this that, if the peak of the

[2]For the explanation of the term "diversity" (diversity-factor) see Insert VI and later Sections 42 to 49.

then, should slightly reduce his demand by one or two kw. the whole conditions would be reversed again.

Evidently these unstable conditions are not only theoretically incorrect but also commercially unsound. The correct point of view can be obtained from the following reasoning:

Let us assume again that the central station has only two consumers *A* and *B*, each of which is using uniformly 500 kw., but, whereas *A* is using his demand only during one hour of the day, from 5 to 6 o'clock, *B* is using his load continually 24 hours a day (Fig. B). Evidently *A* should then be charged less for demand than *B* because such new customers as can be taken on without increasing the capacity of the central station will draw their demand

*The reader who, for one or the other reason, does not care to go into the mathematics of Insert VI may check this statement by considering the obvious facts in the following extreme example: If we assume the load curve of the central station to be a horizontal straight line (100% load-factor), then obviously we have the extreme case of the rounded-off peak and the demand cost of every consumer in that particular case is evidently proportional to his kilowatt-hour consumption because there is no particular moment discernible at which we could assume the peak responsibility to take place. The influence of the consumer's load at any particular moment is therefore in that case not larger than of that at any other moment.

[1]For the definition of this term see Section 26 of the main text.

[2]This would be as logical as if we would charge the first-coming passenger on a car with all the expenses of running that car and let the others ride free, arguing that the car has to run anyway in order to serve the first-coming passenger and the resulting possibility of carrying the later-coming passengers is only a by-product.

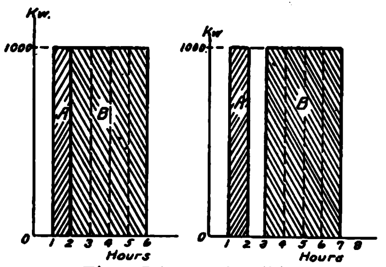
[3]Where the term "Charge" occurs in the text of this investigation it is always to be understood in the accounting sense of the word, that a consumer is considered to be the cause of a certain amount of demand cost but not in the sense that he ought to be made to pay that or any other amount. The cost, moreover, is the average cost and not the increment cost. Price-making is distinctly different from cost apportionment on account of the entering of the element of "Value-of-Service." (This will be taken up in Part II of this series of articles—"The Price of Electric Service.")

from that part of the central-station capacity which is being used by A, whereas B uses his part of the central station all for himself. If both the consumers, A and B, had the same load curve as B, the central station would not have the possibility of taking on any new consumers at any time without increasing its capacity. This principle becomes still more clear if we assume the load curve of the two consumers to be as represented in Fig. C. The "Peak Responsibilities" of A and B in this case still are 500 kw. each and yet it is evident that B should pay higher demand charges than A since by the shape of his load curve he is crowding out practically all possibility of taking on any new consumers with the given capacity of the central station. This possibility has been left open to a large extent by consumer A, but is utilized by B for his own purposes[4].

Finding the Proper Demand Charge Based on the Consumer's Load Curve.

The value of the proper demand charge which ought to be assessed to a customer as cost considering the shape of his load curve, will be found by the following line of reasoning.

Let us again assume two consumers only being on the lines, with a maximum demand of, say, 1000 kw. each, and the shape of the load curves of these two consumers be as indicated in Fig. D (a) or D (b). The total capacity of



Figs. D(a) and D(b).

the central station is then also 1000 kw., and the "Peak Responsibility" of each one of the consumers amounts to the same number of kilowatts. It does not need any elaborate proof that in this case 1/5 of the total charge will have to be charged to A and 4/5 to B[5].

The matter becomes a little more complicated if we assume two customers with the load curves as indicated above in Fig. A. There will be no doubt as to how the demand charges are to be distributed in this case, if we consider the central-station capacity as consisting of two parts, one of 600 kw. which is being used by both A and B, and another one of 400 kw. which is for the use of A only. A will then be charged for

$$(1/5 \times 600) + 400 = 520 \text{ kw.}$$

$$\text{and } B \text{ for } \quad 4/5 \times 600 = 480 \text{ kw.}$$

$$\text{Together} \quad 1000 \text{ kw.}$$

We see that the demand cost which is to be charged to a certain consumer may always be expressed by a certain number of kilowatts. This number of kilowatts will be called the *"equivalent demand."* If, for instance, we had two 24-hour consumers, one with 520 kw. continuous demand and the other with 480 kw. continuous demand, the demand cost would be distributed between the two consumers in the same way as in Fig. A and for that reason the term "equivalent demand" has been chosen. Obviously, the sum of all equivalent demands must be equal to the sum of the peak responsibilities or, in other words, to the central-station peak (disregarding in that latter case the transmission and distribution losses).

Some doubt might arise, however, as to whether the given load curve of B should be really drawn for that purpose as indicated in Fig. A, since there is an infinity of other ways in which a load curve might be drawn for the same load. Some typical examples of the different ways of drawing the load curve of customer B of Fig. A are shown in Figs. A(a) to A(g).* In the "Note"* at the end of this Insert it will be fully explained what effect these different methods of drawing the load curves would have on the distribution of the demand charges, and the proof is given there that the method as used Fig. A is the correct one. In other words, we arrive at the principle that all curves should be drawn in the customary way, that is starting all ordinates from the axis of the abscissae.

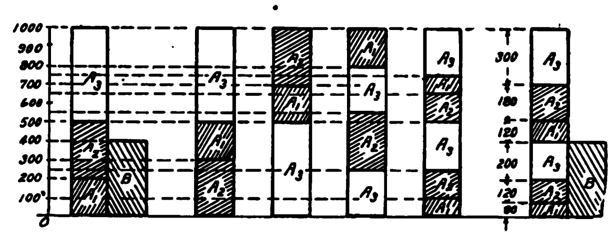
Let us assume as the next step that we have four consumers on the lines, and not more, all of which again shall have a plain rectangular load curve. Three of these consumers A_1, A_2 and A_3 have this in common that they are drawing their current all at the same hour, as shown in Fig. E. These consumers will, for convenience, be called "A-consumers" hereafter. The fourth consumer B is using his demand at some other hour for the same length of time. The amounts of the demand of each consumer in kilowatts can be seen from Fig. E. We can again subdivide the total capacity of the central station of 1000 kw. into two parts as has been done in Fig. A, one part-station of 400 kw. (lower part of Fig. E) being used by the A-consumers first and later by B, whereas the other part-station, of 600 kw. (top part of Fig. E), is used only by the A-consumers and then stands idle during the rest of the day.

The demand cost for the first part of the central station will have to be divided into equal parts, between B on the one hand and the A-consumers on the other hand. It is unknown so far in what proportion the three customers A have to divide their half of the charges for 400 kw. between them.

The second part of the central station has a capacity of 600 kw. and the demand charges for this have to be paid by the A-consumers to the exclusion of B. Here again it is unknown as yet in what relation A_1, A_2 and A_3 ought to divide up these expenses between themselves.

We can no longer, of course, resort to the expedient of just choosing the lower part of the load curve of the A-consumers as the part which is to be charged to the latter and to B in common (as has been done in Fig. A), since we can pile the load curves of the individual A-consumers upon each other in an infinite variety of ways, some of which are shown as examples in Figs. E (a) to E (d). Obviously, each of these methods would then have a different effect upon the distribution of the demand charges.

Evidently those A-consumers who are using that part of the central station which is also used at another hour by consumer B will find themselves at an advantage, so to speak, since they are charged only one-half of the amount



Figs. E, E(a), E(b), E(c), E(d), E(e).

per kilowatt as if they had to use that part of the central station which is used only by consumer A[6].

It appears logical, therefore, to allow each one of the A-consumers to partake of that favored 400-kw. portion in proportion to his own maximum demand. In other words, we divide the total capacity of 1000 kw. into two part-stations, one of 400 kw. which is used by the A-consumers and by B, and the other one of 600 kw. which is used by the A-consumers alone. We then allot a proportional share of each one of these two part-stations to each one of the A-

[4]Readers who have not given much attention to this problem may find it paradoxical that a consumer with a large load-factor (referring the load-factor to the peak responsibility instead of to the maximum demand, as usual) shall be charged with a higher demand cost per kilowatt than another consumer with a smaller load-factor. It has been our mental habit to consider the consumer with a high load-factor a "favorable" one who causes smaller cost than the low-load-factor consumer. We must, however, not confuse the "demand cost per kilowatt" with the "total cost per kilowatt-hour." Even under the theoretically correct principle, explained above, the total cost per kilowatt-hour will be considerably lower for the consumer with large load-factor than for the consumer who with a comparatively large peak responsibility consumes only a small number of kilowatt-hours.

[5]The reader should keep in mind that this Insert is dealing with the distribution of the cost and not with the apportionment of prices.

As regards price-making, the possibilities of using the same central-station capacity at different hours for different customers should be considered as co-ordinated by-products (see Section 4 of the first of these articles) and the price should be made according to the Value-of-Service principle (see later, Part II of this series of articles).

*To be printed in the next issue.

[6]It should be distinctly understood that this investigation deals with the computation of the demand cost which the consumer causes to the central station and not with the demand charges which the central station should make to the customer as a price. The cost, however, is an important, though not the only factor for determining the price (see Part II of this series: "The Price of Electric Service") and the consumer who causes a smaller cost is liable to be charged a smaller price on the average.

consumers. Thus, for instance, consumer A_1 who with his 200 kw. is using 20% of the total capacity of 1000 kw. shall get 20% (=80 kw.) of the 400-kw. station, and 20% (= 120 kw.) of the 600-kw. station. A_2 shall get 30% of each one of the two stations (120 and 180 kw., respectively) and A_3 50% (200 and 300 kw., respectively). This distribution is indicated in Fig. E (e). It is easy now to find out what the charges for each one of these four consumers ought to be, as follows:

A_1	80/2 + 120	= 160 kw.
A_2	120/2 + 180	= 240 kw.
A_3	200/2 + 300	= 400 kw.
B	400/2	= 200 kw.
		1000 kw.

Let it now be assumed as the next step that we have a larger number of consumers on the central station, as per Fig. F. During the first hour we have any number of consumers A_1, B_1, ... E_1, but all with rectangular load curves, using current during the whole hour; these load curves are piled on each other. During the second hour there are also a number of consumers, let us say three: A_2, B_2, C_2, with the same character of load curve as just explained. In the same manner we have a certain number of consumers in every following hour up to and including the n[th] hour (A_n, B_n). Let the small letters a_1, b_1, a_2, b_2.... indicate the number of kw-hr. (or maximum demand, or average demand, which in this case is the same) of every respective customer. Let it be further assumed that h_1, h_2, h_3 be the aggregate number of kilowatts used during each one of these periods as indicated in Fig. F. Let it be further

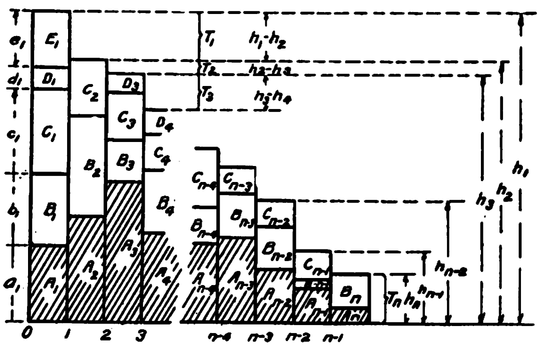


Fig. F.

assumed that the groups of consumers as indicated by corresponding indices are arranged in the order of their aggregate size so that $h_1 > h_2 > h_3 > h_4 >$ ....

What will then be the equivalent number of kilowatts, K_{a1}, for which customer A_1 will have to be charged?

The total capacity of the central station necessary for all customers mentioned will be h_1. Let the central station of this size be subdivided again into n small part-stations T_1, T_2 ......T_n of the respective sizes $(h_1—h_2)$, $(h_2—h_3)$, ... $(h_{n-1}—h_n)$, h_n (see Fig. F).

The first-named central station T_1, which has the capacity of $h_1—h_2$ kw. and is represented as the uppermost part in Fig. F, is being used not longer than during one hour, as can be seen from Fig. F. The second station T_2, of the size $h_2—h_3$ is being used during two hours. The n[th] central station or part central station of the capacity of h_n kw., which occupies the lowest part of the diagram Fig. F, is being used during all the n hours. According to what has been said above, we will have to apportion a certain part of the demand of A_1 to the first-named central station T_1, another part of A_1 to the second T_2 and so on, a certain part to each one of those past central stations. The size of the part of A_1 apportioned to the top central station T_1 will be $a_1 \times \frac{h_1 - h_2}{h_1}$. The part allotted to the second central station T_2 will be $a_1 \times \frac{h_2 - h_3}{h_1}$, and the part belonging to the last central station T_n will be $\frac{h_n}{h_1}$. The demand cost for the part apportioned to the first central station will have to be charged to A_1 alone. Of the demand cost of the central station T_2, only one-half will have to be charged to customer A_1, whereas the other half is charged to such other customers as are using central station T_2 during the second hour. In the same manner we will continue and finally find that the charges for that part of a_1 which is allotted to the n[th] or bottom central station are divided into n parts of which only one is to be paid by customer A_1.

The total charges of A_1 expressed in equivalent kilowatts (that is, the "equivalent demand" in kilowatts) are therefore

$$K_{a1} = \frac{a_1}{h_1}\left[\frac{h_1 - h_2}{1} + \frac{h_2 - h_3}{2} + \frac{h_3 - h_4}{3} + \frac{h_m - h_{m+1}}{m} + \ldots \frac{h_{n-1} - h_n}{n-1} + \frac{h_n}{n}\right]$$

In the same manner the equivalent maximum demand for A_2 will be found as

$$K_{a2} = \frac{a_2}{h_2}\left[\frac{h_2 - h_3}{2} + \frac{h_3 - h_4}{3} + \ldots \frac{h_m - h_{m+1}}{m} + \ldots \frac{h_{n-1} - h_n}{n-1} + \frac{h_n}{n}\right]$$

or, in general, of the customer A_m

$$K_{am} = \frac{a_m}{h_m}\left[\frac{h_m - h_{m+1}}{m} + \ldots \frac{h_{n-1} - h_n}{n-1} + \frac{h_n}{n}\right]$$

Let now all the consumers characterized by the letter A (that is A_1, A_2, ... A_n) be combined into one new consumer A, whose load curve is represented by the shaded part of Fig. F. Then evidently the demand charge of this consumer A is the sum of the demand charges of A_1, A_2, ... A_n, and the equivalent maximum demand of A is the sum of $K_{a1} + K_{a2} + \ldots + K_{an}$.

If we call the quotients $\frac{a_1}{h_1}$, $\frac{a_2}{h_2}$, ... $\frac{a_n}{h_n}$ for the sake of brevity q_1, q_2, ...q_n, then we get by carrying out the addition of $K_{a1} + K_{a2} + \ldots + K_{an}$:

$$K_a = (h_1 - h_2)q_1 + (h_2 - h_3)\frac{q_1 + q_2}{2} + \ldots + (h_m - h_{m+1})\frac{q_1 + q_2 + \ldots q_m}{m} + \ldots + (h_{n-1} - h_n)\frac{q_1 + q_2 + \ldots + q_{n-1}}{n-1} + h_n\frac{q_1 + q_2 + \ldots q_n}{n} \ldots (1)$$

In order to get a method of geometrical construction for this formula we proceed as follows: q is an abstract number and in order to represent it geometrically we have to select a certain length as unity. For reasons which will become obvious later it is most convenient to select the capacity of the central station h_1 as unity. The construction of the value $q_m = a_m/h_m$ is then a simple elementary procedure.

Those parts of Fig. F which are essential for the following have been repeated in Fig. G, that is, the total load curve (staggered curve h) and the load curve of customer A (staggered curve a). The amounts for q are entered into Fig. G as dash and dot lines. Evidently for the first interval of time $o1$, q and a are identical on account of the choice of the unity.

The term $(q_1 + q_2 + \ldots + q_m) / m$ obviously represents the arithmetical mean of the ordinates q between the abscissa O and the abscissa of the end of the m[th] interval of time. This term will, for the sake of brevity, be called f_m hereafter. Thus, for instance, f_3 in the third interval of time is found as the arithmetical mean of q_1, q_2 and q_3 or $(q_1 + q_2 + q_3) / 3$. The curve of f is also entered in Fig. G.

Introducing the term $f_m = (q_1 + q_2 + \ldots q_m) / m$ into equation (1) we have

$$K_a = (h_1 - h_2)\, f_1 + (h_2 - h_3)\, f_2 + \ldots\ldots (h_m - h_{m+1})\, f_m + \ldots (h_{n-1} - h_n)\, f_{n-1} + h_n f_n \qquad (1^*)$$

If we step off now (Fig. G) the length $f_1 = OF_1$ horizontally to the left from the point H_1 (situated on the axis of ordinates) as $H_1\, g_1$ the rectangle $H_1\, g_1\, G_1\, H_2$ will by its area represent the first term $(h_1 — h_2)\, f_1$ of equation (1*).

In the same manner, if $H_2\, g_2$ is made equal to f_2 of the second interval 1-2 of time, the rectangle $H_2\, g_2\, G_2\, H_3$ represents by this area the second term $(h_2 — h_3)\, f_2$ of equation (1*).

By stepping off the lengths f_1, f_2, f_3 ......f_n horizontally in the manner indicated, we get the shaded surface in Fig. G, the area of which is a measure of K_a according to equation (1*). The length OH_1 has been assumed as unity. If, therefore, the shaded area in Fig. G is transformed into a rectangle over the base OH_1, the height of this rectangle will be equal to the equivalent demand K_a of customer A. The kilowatt scale will be the same as that of the load curves.

The intervals of time 0-1, 1-2, 2-3,......(n — 1)-n, in Figs. F and G have been assumed so far for the sake of convenience to be of one hour's duration. Evidently, however, the absolute lengths of these intervals have nothing to do with the above reasoning as long as the intervals are equal among each other. We can, therefore, without influencing the result, reduce the lengths of these intervals more and more, at the same time increasing their number, until we get down to differentials. This will change the staggered curves of Fig. F and G into smooth continuous curves (Fig. H†).

Nor has the order in which the intervals of time follow upon each other any influence on the amount of the equiva-

†See continuation in next week's issue.

lent demand. So far it has been assumed that the load curve of the central station is of such nature that it starts with the peak load and that the load curve of the central station is steadily falling from the left to the right. This, however, is an assumption which in practice will hardly ever be fulfilled. The load curves go up and down in an irregular manner and have one or more peaks and valleys (maxima and minima).

We might now just as well have had the time intervals of Fig. F arranged in any other order than what Fig. F shows without causing any change thereby in the amount of the equivalent demand, as long as the demands themselves are not changed. For instance, the time intervals might be arranged so that the staggered duct of lines first rises and then, after reaching a maximum h_1, falls again or they might be arranged to form several peaks and valleys in the central-station duct of lines. The resulting equivalent demand will not be changed by this, because it is not essential that, for instance, the interval with the central-station load h_2 is to the right of the interval with load h_1 (Fig. F) nor that it immediately adjoins it. We can follow exactly the same line of reasoning and come to the same conclusions if this is not so. But it is more convenient to have the intervals arranged in the order of the magnitude of their respective central-station load, especially where the load curve is no longer a duct of horizontal straight lines but a steadily curved line, in other words, where we have an infinitely large number of infinitesimally small time intervals.

The first problem to be solved in a practical case is, therefore, the transformation of the load curve of the central station into another curve by a transposition of the time elements so that the latter are arranged in the order of the corresponding central-station loads, beginning with the highest load (peak load) at the extreme left and ending with the lowest. Designating the original central-station load curve as curve B (Fig. I†), we will by this rearrangement transform the B curve into a curve corresponding to the duct of lines with the ordinates h_1, h_2, ... (Fig. F). The

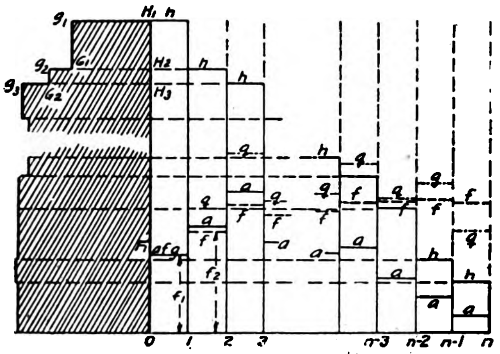

Fig. G.

resulting curve will for that reason be designated as the h-curve. It will steadily fall from the left to the right, or at least rise nowhere to the right.

This transformation of curve B will also result in a transformation of curve b, that is, of the load curve of the individual consumer whose equivalent demand we wish to determine. Every moment of time—to whichever position it has been shifted—must always remain connected, not only with the same central-station load which it had originally as per curve B, but also with the same load of the individual customer as given by curve b.

The customer's load curve thus changes into another curve to be called curve "a" hereafter because it corresponds to the shaded part of Fig. F, that is, to the aggregate of the load curves of all consumers A.

From "h" and "a" the curves "q," "f" and "g" will be found successively, the meanings of which have been explained before. Finally, by transforming the area under curve "g" into a rectangle the equivalent demand of the customer with the load curve "b" is obtained as the height (or rather width) of that rectangle in the horizontal direction.

These operations, although not very simple, still are not as intricate as it may appear at first sight and they are made in less time than it takes to describe them. The construction of the various curves will be described in the continuation of Insert VI in the next issue.

†To appear in the next issue.

(To be continued.)

REPORT ON GOVERNMENT WIRELESS TELEGRAPH STATIONS.

Extracts from Census Bureau's Report on Telegraph Systems of the United States in 1917.

The United States Bureau of Census has issued a report on the telegraph systems of the country during the year 1917 and the five-year period 1912-1917. Extracts from that report were published in our last issue. The following data, also from this report, deal with the Government's radio stations.

The Government has erected wireless plants at various points along the Atlantic and Pacific coasts and at Pearl Harbor, Hawaii, and Cavite, in the Philippines. The Government shore stations, according to the reports of the Bureau of Navigation numbered 135 on June 30, 1918, of which 88 were in continental United States, 20 in Alaska, 19 in the Philippine Islands, 3 in the Canal Zone, 2 in Hawaii, and 1 each in Porto Rico, Guam, and Samoa. The Government ship stations totaled 470.

The station at Arlington, Va., has been in regular communication with the station at Chollas Heights, near San Diego, Cal., since May 1, 1917. Direct communication with an Italian Government station in Rome was also established. On Sept. 29, 1917, radio communication was established between Arlington and Pearl Harbor, Hawaii, via Sayville, N. Y. Messages are now transmitted between Arlington and the Philippines through San Diego, Cal., and Pearl Harbor, Hawaii. Under favorable conditions, at night, the Arlington station can communicate directly with the Pearl Harbor station, but the usual practice is to relay through San Diego.

IMPORTANCE OF CO-ORDINATING POWER SUPPLY RECOGNIZED IN ENGLAND.

One of the matters given much attention at the recent convention of the Incorporated Municipal Electrical Association of Great Britain was the proposed interconnection and rehabilitation of that country's power supply systems, which was referred to at length by President Frank Ayton.

In Mr. Ayton's opinion, the need for the reorganization and the co-ordination of electric supply had been abundantly proved. The electric supply industry was now, as it were, part and parcel of the manufacturing organization of the country; its future and its prosperity were indissolvably linked up with that of the nation's industries. Electric power, cheap and abundant, was clearly one of the main necessities for export trade.

PENNSYLVANIA ASSOCIATION PLANNING IMPORTANT CONVENTION.

The annual convention of the Pennsylvania Electric Association, which is a geographic section of the National Electric Light Association, will be held at the Bedford Springs Hotel, Bedford Springs, Pa., on Sept. 3 to 6, inclusive. Although no definite features of the technical program can as yet be announced, it may be safely stated that the convention will be along the lines of those that were so successfully conducted and so largely attended before our entry into the war. An exhibit by manufacturers of electrical equipment is to be held as an important feature of the meeting. H. M. Stine, 211 Locust street, Harrisburg, Pa., is secretary of the association.

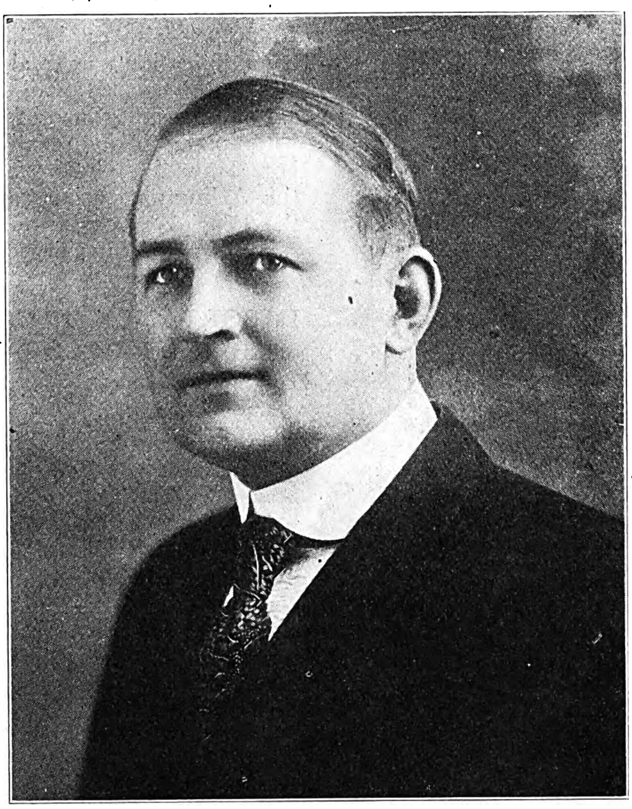
Complete Electrical Equipment for the Home

Paper Read Before National Association of Electrical Contractors and Dealers Describing Plan to Popularize Use of Convenience Outlets

By JOHN G. LEARNED

Chairman, Commercial Section, National Electric Light Association.

THERE exists a community of interest among electrical manufacturers, jobbers, dealers, contractors and central stations in the fostering of the complete electrical equipment of the home. Therefore, the plan of the National Electric Light Association, Commercial Section, to bring about a nationwide educational campaign for the purpose of creating a greater demand for complete installations of wiring and appliances in the home should meet with favorable consideration.



John G. Learned.

Assistant to the Vice-President, Public Service Company of Northern Illinois.

Although the electrical industry has made most remarkable strides in the last 25 years we have been woefully deficient in focusing our efforts on educating the public to the unit idea of electrical equipment in the home. Electric lighting installations are fairly well handled, although there is vast room for improvement, whereas the necessity of an adequate number of outlets for the use of portable and electrical appliances has been sadly neglected by comparison. The future permanent success of the "Residence Service" of our business depends largely on our ability to so thoroughly educate the public that the layman and laywoman will be as conversant with the complete unit electrical equipment of the home as they are now with the electric starter, the electric headlight, the electric horn and the other refinements of the automobile. There never was a more opportune time than now, especially on account of the present shortage of household help.

The Commercial Section of the N. E. L. A. plans to get the manufacturers of electrical heating appliances, washing machines, vacuum cleaners, portable lamps, fans, vibrators, hair dryers, sewing machines, etc., accessories and other appurtenances used in the home, to include in their national advertising an illustration of the baseboard or wainscoting receptacle. The idea being to show the particular appliance advertised and the cord connecting it to a receptacle, which can be done without any additional expense. Those manufacturers who have had this matter brought to their attention are very enthusiastic and have already taken steps to co-operate.

Central-station companies are having this matter brought to their attention and are being urged to feature appliance outlets along the same lines in local newspaper advertising, on billboards, customer's bills, and salesroom advertising. Department stores will be urged to follow suit. Jobbers, dealers and contractors should also get behind this campaign, which is not for a week or a month, but continually. The results will be accumulative.

Another method of bringing the message home is to make up window displays of appliances with their cords connected to receptacles mounted on sections of baseboard or wainscoting.

Coffee dealers, packers and other manufacturers will be asked to use electrical appliance illustrations showing the cord attached to a receptacle in their national advertising, instead of the alcohol appliance now used. Special attractive advertising in pamphlet form on this subject—receptacles—will be prepared for distribution to architects by the central stations.

Below is quoted the advertising manager for a well-known electrical manufacturer who is particularly enthusiastic on the subject:

One way to increase the interest and therefore the installation of more adequate provisions for use of electrical appliances in the home is to form a small committee to outline a complete campaign to cover a given period of months. Some of the things to be done are as follows:

1.—Prepare cuts of several sizes and kinds to be furnished to all manufacturers of electrical goods and to have these cuts used similarly to the Liberty Bond and War Savings Stamp cuts in advertisements over the period selected. These cuts will therefore act as constant reminders to all of us in the electrical industry and those cuts used in the national media by the various manufacturers who advertise in such publications will help to bring home this campaign to the public in general. These cuts can also be used in the various folders, literature and on letter-heads, during this same period regardless of what the folders or other literature describe.

2.—Special Folders and Other Printed Matter.—Folders and other small pieces of printed matter to be prepared especially on this subject of the advantages of more adequate equipment for the use of electrical appliances, and this material used as envelope stuffers by lighting companies, manufacturers and their district offices, engineers, electrical jobbers and electrical contractors and dealers. A good portion of these stuffers would therefore reach the hands of the public also.

3.—Small Stickers for Letterheads.—A series of these could be prepared, covering the subject which could be used over a period specified in the campaign by the same groups mentioned above. Many of these, in this way, would come to the eyes of those interested in building.

4.—Manufacturers making such devices which would be used in installing adequate equipment in the home would be urged to extend their advertising and concentrate on devices such as receptacles, etc., during the period decided upon for this campaign. These same manufacturers will furnish to the dealers, contractors and lighting companies small electros and other suggestions, advertisements and folders, which could be used for local and newspaper advertising by these concerns.

Recent Advertisement showing how other industries apply electrical idea to their advertising. In accordance with the new plan such advertisements will show the washing machine connected to a convenience outlet.

5.—Little stories, articles, and illustrations could be prepared for the various electrical journals as well as some specially prepared for the general publications and particularly for *Good Housekeeping, The Woman's Home Companion, The Ladies Home Journal, House and Garden, Woman's Magazine, Today's Housewife, Delineator,* etc.

Undoubtedly the persons preparing these articles for such magazines will co-operate and have the need for adequate outlet equipment emphasized in these articles and, possibly, have at least one article devoted just to that one subject alone.

6.—Electric lighting companies during this period could also be instructed to attach slips to the electric lighting bills, such slips to carry a message concerning the convenience of more adequate wiring of the home.

7.—At the same time, the architects and electrical contractors figuring on wiring jobs should be urged to bring the matter of convenient outlets to the builders' attention, since a good many people still are not familiar enough with electrical work to appreciate the wonderful convenience of having many outlets, as for instance, in the baseboard and do not realize that the addition to these outlets does not mean very much greater cost when figured over a period of say five to ten years.

8.—Short Movie Films and Slides.—There are a number of companies prepared to make up movie films which are produced in such a satisfactory manner that the moving picture houses throughout the country are glad to make use of them in connection with their usual programs. In such films, a very forceful appeal can be made and the convenience of many outlets can be played up in a pleasant though distinct manner and the disadvantage of a poorly equipped home emphasized. The mind of the theatre goer is in a particularly receptive state when looking at the screen and such films in connection with other slides advertising the installation of various receptacles by local contractors and lighting companies will tie up very strongly with the other promotion work.

9.—The subject matter for advertisements might play up the saving in wear on electrical fixtures; the great convenience of electrical appliances made still greater by the provision of adequate outlets or attaching places for the ready connection of electrical appliances in various rooms, to electrical circuits. Safety could be emphasized also.

10.—Various little stickers for use on letter-heads might have subjects similar to the following:

When Wiring Your Home Have Outlets Arranged for Your Electrical Appliances.

Double Electrical Conveniences—Have Extra Outlets for Electrical Appliances.

Save the Wear on Electric Fixtures—Connect Your Electrical Appliances to Baseboard Outlets.

Have Extra Outlets in Your Laundry as Well as in Your Living Rooms for Your Electrical Appliances.

Electricity Is Your Servant—Have Outlets Installed for Your Electrical Appliances.

In Wiring Old Houses Install Well-located Electrical Outlets Generously.

Provide Complete Electrical Installations in New Houses—Especially Outlets for Appliances and Lamps.

Numerous Faucets Are Provided in the Home for the Convenient Use of Water. Why Not More Outlets for the Use of Electrical Appliances and Lamps?

More Outlets for More Business.
More Electrical Outlets—More Satisfied Customers.
Extend Electric Service by Installing More Outlets.
Don't Rob Peter to Pay Paul.
Install more outlets for the simultaneous use of Electrical Appliances as well as Electric Lighting.
The Modern Home Uses Electric Service.
Extra outlets in each room for the convenient use of Electric Appliances
Solve the servant problem.
For Quick Convenient Use of the Electric Heating Pad Provide an Extra Outlet in Your Bed-room.
In Nearly Every House Now-a-days Some Provision is Made for the Use of Electricity, but Very Often too Few Outlets Are Installed for the Convenient Use of Electrical Appliances and Portable Lamps.
To Rectify Such Omission After the House Is Built Is Expensive.
MORAL: Make your Electrical installations complete at first. Install extra outlets in every room.
Electricity Will Increase the Value of Your Property Many Times Over the Small Cost of the Investment. Be Sure Your Installation Is Complete. Install One or More Extra Outlets in Every Room for the Use of Electrical Appliances and Portable Lamps.

These ideas are formed only in part but they can serve as a starting point and could be developed into a more complete form and augmented after a little conference on the subject. With any kind of work it is easier to have some actual start than to just talk the matter over.

In addition the following are some ideas intended to suggest slogans and text matter which might be further developed for use in support of a campaign for more electrical outlets.

Let out Pent-up Electric Service by Installing More Outlets.
Electrical Outlets Increase House Values
Provide one or more extra outlets in the floor, baseboard or wall in every room for the convenient use of Electrical Appliances and Portable Lamps.
Modernize Your Home with extra outlets for the use of Electrical Appliances.
Take Full Advantage of Electric Service Install extra outlets in every room for the use of Time and Labor-Saving Devices—Electrical Appliances.
Extra Outlets for Electric Portable Lamps —for Utility and Beauty.
Extra Outlets Promote Sale and Use of Electrical Appliances and Lamps.
Insufficiency of Outlets Restricts Use of Electric Service
Increase sales of Electrical Appliances and Lamps. Install one or more outlets in every room of every home.
Mr. Business Man—You use several telephones in your office for good business reasons; also for convenience. How about your Home? Extra Outlets in each room permits the convenient use of time and labor-saving devices—Electrical Appliances
Give a thought to the wife. Install more electrical outlets.
For Comfort, Convenience and Economy Install Extra Outlets for Electrical Appliances and Portable Lamps.
Do a Good Job While You Are About It.
Don't Skimp on Electrical Outlets.
An Extra Outlet or Two Installed on the Porch Will Be Found Useful for Attaching the Electric Fan or Portable Lamp.
Install Outlets in the Halls for Use of the Electric Vacuum Cleaner.
The Completely Electrified Home Will Remain Modern for Years to Come. Install Plenty of Outlets.

In conclusion, what has been stated only skeletonizes some of the ways of doing that which we have in mind. It remains for the contractor-dealer to get behind this movement, as it is self evident that although the central stations are the principal beneficiaries, it is to the mutual advantage of every one engaged in the industry. It follows as a matter of course that if this work is taken up in a big way as outlined that the public will be educated to the necessary degree, with the result that a big demand will be created for wiring, receptacles and appliances.

And, as a result, the contractor will do more wiring, the dealers will sell more appliances, the jobber will do more business, the manufacturers will turn out a larger volume of products, the central station will enjoy more revenue, and last, but not least, the consumer will enjoy complete "Residence Service."

JAPANESE COMPETITION IN ELECTRIC CABLES DECLARED TO BE FAIR.

A Japanese Electrical Engineer Connected with General Electric Co. Denies Statements of Our British Correspondent.

To the Editor:

In the June 28, 1919, issue of the ELECTRICAL REVIEW there was made public an article entitled "Japanese Competition in Electric Cables," which aroused my keen interest or rather regret because of the misleading information quoted in it.

It is true that little inroads were made by Japanese cable manufacturing concerns during the past two or three years into the British trade connection with India and the British colonies, but it is utterly false that Japanese workpeople receive 12 cents per day of 12 working hours or 1 cent per hour. No page of Japan's labor history gives any record of such a cheap payment. The average wage at present is, roughly, $1 per day of 9 working hours.

That article further says that the Japanese copied the British labels as well as the British cables. Although I am not connected with any Japanese cable manufacturer economically, this remark could never be passed lightly over because it is an insult to our national fame. Electric cables exported to British oriental colonies were solely manufactured by the Yokohama Electric Wire Works, which is located in Yokohama, Japan, and that company has never used an inspection "C. M. A.," the mark of the British Cable Makers' Association, with the little word "not" which might easily be overlooked, as described in your magazine.

Schenectady, N. Y., July 15, 1919.

F. OHASHI.

GOVERNMENT OF CHILE APPOINTS HYDROELECTRIC COMMISSION.

According to recent press notices the Government of Chile has created a commission to study the hydroelectric possibilities of that country with a view to developing its natural water-power resources for this purpose. It is the intention to construct a series of hydroelectric power stations which will be tied together through an extensive longtiudinal system. In this way the electric power derived from the waterfalls will be made available over a long stretch of territory.

This country is particularly well adapted to such development for many of its vast water-power resources are but a short distance from its larger cities and industries and there is also a considerable demand for power for mining purposes. In addition, coal and other forms of fuel are comparatively scarce and expensive.

A Perspective Glance at the Future of American Business

Calm Survey of Conditions in Europe and the United States—Unfortunate Letting Down of Production Here —Need Is to Increase Effort Rather than the Reverse

By CHARLES G. DU BOIS

President, Western Electric Co., Inc.

EVIDENCES are plentiful that a considerable portion of the American public does not recognize the opportunities and responsibilities before it in the industrial and commercial field. Leaders in American business feel that the country must be aroused on this matter. One of the clearest statements on this topic yet presented is the one by Mr. Du Bois published herewith. The points he makes should be carefully and thoughtfully considered by not only electrical men, but by those in other industries, and by labor as well as by capital.

THE Great War is ended and the day of reckoning has come. The victorious allies rightfully hold the criminal German rulers to account for their crimes and the German nation to make reparation up to the limit of its ability. But even while we continue to rejoice in this victory, we should be seeking to see as clearly as we can, and in its true perspective, the economic situation that is immediately before us. It is not a problem to be worked out only by a few statesmen, assisted by experts. We all need to understand it because we shall all have a part in it and its solution is fraught with incalculable importance to ourselves and the generations that are to follow us.

At the risk of attempting too much, let us consider in their relations to each other the main features of the present economic and social situation as they bear on our own material prosperity.

By reason of the much longer and greater strain on the European nations during the war, they are in a far more disorganized condition now than America and they are thus unable to proceed as rapidly with the conversion of war activities into normal peace activities. Europe needs our products and, until its own industries are completely re-established, we must take our pay, not in money or goods, but in securities—that is, promises to pay at some future date. From a purely selfish standpoint, America as a creditor nation wants other nations to prosper so they can buy our goods, can pay the interest on their debts to us, and can eventually liquidate the principal.

And as to our domestic situation, we have to remember that our war activities created employment for everyone, and to that extent made for generally prosperous conditions. It remains to be seen to what extent such prosperity was merely temporary. Even while it lasted, some of it was more apparent than real. Wages increased as the cost of living went up and the cost of living in turn increased as the wages that constitute most of the cost of every article went up. This process, as everyone knows, can create no prosperity for us as a whole, for though it has affected many individuals favorably, many others have been compelled to seriously curtail.

During the war there undoubtedly was a greater prosperity than normal, but it had another cause. This was that everybody worked and everybody, whether voluntarily or by compulsion, saved. Since we worked harder, we produced more than ever before, while at the same time we consumed less and wasted much less. This greater net production aided considerably toward paying our war cost but still it left an enormous amount—judged by pre-war standards—to be paid in the future.

We are only now really facing this future. The great joy and relief we all felt when the armistice was signed last November and we knew that at last all fear of German world domination was over, has been followed in the succeeding months, as was only natural, by a letting down of effort which, though it may be small in each individual, has been and is, in the aggregate, stupendous.

That part of the war production which was at the cost of undue strain and fatigue is, of course, no longer necessary or justifiable, but, making full allowance for this, the present let down of effort from the war standard represents a serious loss in production.

Moreover, this material loss is accompanied by a mental unrest that threatens even more serious consequences. The relief from the emotional strain of war affects us all. Some realize soberly the difficulties that must be surmounted and appreciate that the only practical course of action is to work steadily ahead under the existing conditions. Others, who are less practical or whose minds have been inflamed by visionary ideas or strained perhaps by personal misfortune, think they see the dawn of a millennium and demand swift and radical economic changes in the unreasoning hope that somehow a great betterment will result.

The desperate conditions in eastern Europe have produced the most violent reactions. Where society has become so disorganized that the ordinary methods of production, distribution and trade have broken down, idleness results from the disorganization, and hunger inevitably follows idleness. To starving men, anything seems better than starvation, so bolshevism, which promises everything and by criminality gets something for a while, seizes its opportunity.

All this is like jumping off the precipice because the road is rough. Civilization itself depends on the maintenance of law and order. Without them the world would quickly fall into chaos, so that governments only fulfill their primary function by dealing swiftly and sternly with all attempts to overthrow by force this fundamental principle. This must be so, whatever sympathy may be felt for those whose misfortunes or weak judgment have made them the dupes or tools of criminal fanatics.

The conditions in America are so much better than in any of the war-stricken countries, are indeed so prosperous, that we need not really fear any large movement here toward any form of anarchy. But the great safeguard against it is to preserve our present prosperity till the strain in Europe has passed.

It is idle to suppose that material prosperity can be maintained except by continuous production; in fact, the extent by which we can intelligently increase production measures the increasing volume of prosperity.

The modern organization of industry by which goods are designed, produced, sold and transported has undoubtedly been the foundation of a material prosperity, such as was never before conceived. It has its imperfections, as have all human affairs, but it has, in a democracy at least, the means of self-correction, it has greatly stimulated invention and scientific research, and above all, it does operate the machinery of production and distribution so that men have food, clothing and shelter and a chance to improve their condition. This machinery has just successfully stood the unprecedented strain of war demand for production. The real problem before us is to keep it in adjustment under the less spectacular conditions of peace. And yet perhaps these conditions rightly considered are no less inspiring.

For we look not only to helping Europe and so safeguarding ourselves but, by the means of material prosperity, we think of a better America than we knew before the war. And that better America to deserve the name, must mean better working and living conditions, so that all who are willing to work may have continuous opportunity to do so and may participate fully and fairly in the product of their labor. We want better cities, better homes, better schools, better rural conditions. But we know such betterments can only come by greater efforts than we have yet made.

The achievement of all these objects seems clearly possible if we can get a clear perspective of the situation so that we see all its parts in their true relations to each other and as together making one complete picture. If we can get that perspective, we shall see what our course of action ought to be.

Does it not point directly toward increasing just so far as we can the total production of the country? Rather than a lessening of effort, is it not the time to increase our effort, both for quantity and quality? Shall not such effort be toward wresting from nature more of her secrets, and by applying to them the work of our brains and our hands get a future yield which will make that of the past look meager? Or shall we be content with the total of what we have had and spend the rest of our strength in quarreling over its division? The one way is full of inspiration and promise, not only for a better America but for a better world. The other is both toilsome and unfruitful and only seems easy because we are used to it.

Can there be any doubt that America, in this hour of her opportunity for economic leadership, as well as moral leadership of the world, will choose what seems the harder but viewed in the whole perspective is both the easier and the greater course?

ELECTROCHEMISTRY IN ITS HUMAN RELATIONS.

Timely Extracts from Presidential Address Before Last Meeting of American Electrochemical Society.

By F. S. Tone.

We are human beings as well as electrochemists, and we may well study the relations of our science to the world problems of today and how we can give most immediate and most effective service for the betterment of human society.

For four years we have been in the thraldom of a great war. We have been passing through a period of violent evolution, the nature and extent of which we have hardly begun to measure or realize. Science and industry and, in fact, every human activity emerges from this world turmoil with new and rapidly shifting viewpoints and new responsibilities, and electrochemistry forms no exception. It is therefore profitable at this time to take some survey of our present situation and to forecast our future activities and responsibilities in the new alinement of human relationships. If a new era has begun, what is our part in it?

As one of the big results of the war, new and better conditions of living are demanded by the masses of the people in all countries. If a higher plane of living in the matter of food, clothing, housing, fuel and sanitation is to be established, and if shorter hours of labor and more opportunity for recreation and self-improvement are to be the order of the new day, this can only be brought about by vastly increasing the production of all the essentials which enter into the needs of modern society. Not forgetting such factors as co-operation, efficiency of organization and distribution and elimination of wastes, production can be increased principally in two ways: First, by using labor more efficiently, and second, by further supplementing and supplanting labor by the chemical and mechanical instrumentalities of industry. Either we must get more out of labor or we must stimulate the discoveries that will make labor more productive than before. If the world is going to work less, science must work more. The work of the world cannot be done in a 6-hour day and 32-hour week unless applied science gets in a lot of time-and-a-half on weekdays and double time on Sundays.

Food and Fertilizer.

Among the problems of first importance is that of the world's food supply. The crop yields of the world must be vastly increased, and this in the face of a decreasing labor supply. If cereals, cotton and animal fodder must be produced in greater quantity and more cheaply, the answer can only be found in improved transportation and traction for the farmer and in a vastly extended use of fertilizer, and here rests a big problem with the electrochemist. Judged by European standards, the American farmer is inefficient. He produces 14 bushels of wheat to the acre while in Europe the same acre yields 30. European yields all along the line average from 50 to 100% greater than American yields, and while this increase is in part due to intensive farming, better selection of seed, and crop rotation, the big difference is in the enormously greater use of fertilizer. It is of the highest economic importance that the American farmer shall use more fertilizer.

The three main elements of plant food are nitrogen, potash and phosphoric acid, and each one of these carries a problem for the electrochemist. The fixation of nitrogen is one of the great triumphs of electrochemistry, and the possible exhaustion of the natural nitrate fields is to us no longer a matter of any anxiety. So long as we have energy and air the land need never want for ammonia. Still the efficiency of the arc process of fixing nitrogen is today less than 5%, and between this figure and the best efficiency attainable, there is certainly breathing space for the most energetic of our research workers. The extension of the cyanamid process has been one of the remarkable chemical events of the war. Its opportunity for peacetime accomplishment is no less, but we still have some distance to go before artificial nitrates can be laid down to the farmer in such quantity and at such price as will mean the doubling of our crop yield.

The potash problem during the war has been brought into the field of electrochemistry. The Cottrell system of electrostatic precipitation has been successfully applied to gases from blast furnaces and cement plants, and if the waste gases from all such plants were treated by the Cottrell process, the possible recovery of potash would be equal to our pre-war consumption. We can hardly hope that this is commercially possible, but in many localities it will give a permanent source of potash which will maintain its existence under competitive conditions. What the electric furnace can do in phosphoric acid recovery is not so well proved. But passing over this, we see that the solution of our national food problem is one in which, despite our past accomplishments, we still have large responsibilities.

Sanitation Through Use of Chlorine.

In the new order of things we are going to banish the slums and have more healthful living conditions, and the role of the electrochemist in sanitation is told in the story of chlorine. We learn that when the armistice was signed we were just ready to deliver each day to our fighting forces on the western front over 200 tons of poison gas. The basis of this great offensive weapon was chlorine, and it was denied its opportunity to demonstrate in a big way what it could do to win the war against the Huns, but I believe it has a far greater opportunity in the germ warfare of peace times.

In starting to investigate the work that chlorine is doing in sanitation, I knew in a general way that it was of growing importance in the purification of drinking water, but upon assembling all the data it was astounding to find that chlorine is today making safe the drinking water of more than 20,000,000 people of this country who dwell in cities. Chlorine is safeguarding one-fifth of our population from typhoid. We learn that a military force or an industrial expedition can go anywhere in the tropics and be at all times assured of potable water if it carries a few pounds of hypochlorite. In the Carrel-Dakin solution for the treatment of wounds, the use of chlorine is defined by a recent authority as the greatest discovery of surgery in the whole war. During the recent epidemic of influenza, the number of cases in the cell rooms of two electrolytic chlorine plants, located in different states, was one-half of that in any other portion of the plants. Starting with a few such facts as these, what more is needed to build up a great structure of organized sanitation with chlorine as its basis? We are looking for an outlet today for a huge producing capacity brought about by the demands of the war. Do not these examples of what chlorine is doing in germ warfare clearly point the way?

The sterilization of sewage is as logical a measure of sanitation as the sterilization of drinking water. To be sure, no city drinks its own sewage, but some other city generally does. Why permit Chicago and Milwaukee, Detroit and Cleveland to pollute the waters of Lake Erie, Lake Ontario and the St. Lawrence Why should Pittsburgh pass its germ-laden water on to Cincinnati and Louisville when an adequate remedy is available at reasonable cost? One hundred and twenty pounds of hypochlorite will sterilize 1,000,000 gallons of screened sewage. A city of 1,000,000 inhabitants can sterilize its sewage at a cost for its chemicals of $360 per day. The cost per single inhabitant for one year would be about 12 cents. But the work of chlorine does not stop with water supply and sewage. It should be used to flush and sprinkle our streets, to clean our cars and public buildings, and to sterilize our dairies. The organized use of chlorine in sanitary milk production will do more to give our children a pure milk supply than any possible system of inspection.

We are searching for an outlet for our excess chlorine in metallurgy and in organic chemicals. If our electrolytic chlorine friends would begin telling people how they can live in a prophylactic environment, how they can feed their babies pure milk, and how they can avoid poisoning their neighbors who live lower down on the same watershed, conditions in the chlorine market would soon be such that they would no longer worry about what the Government is going to do with Edgewood.

Electric Steel and Alloy Steels.

Again, in the metallurgy of steel, if electrochemistry has made great contributions to the art, its responsibilities are no less clearly defined. No one now doubts that we shall soon attain to the super-steel, and it is no less clearly indicated that this will be accomplished by the electric steel furnace and electrically produced alloys. The triplex process using the electric furnace as the third step for the refining operation produces a steel of crucible quality at a cost of a few dollars a ton more than open-hearth steel. When it is understood that such steel produces rails which do not break and plates which do not fracture, it will require no advertising campaign in the popular weeklies to bring this product into universal use: public opinion will demand it. The alloy steels have made possible the modern automobile, the airplane engine and the farm-tractor motor. Alloy steels have been a luxury. They have been used only in the vital parts of the mechanism where enormous strains must be met with a minimum weight of material, but their use must be extended. High quality is not incompatible with tonnage. It is the work of the electrochemist to make possible their use as common materials of engineering, thus contributing vastly to improvements in transportation and the mechanical arts. No one needs to have pointed out what this signifies as an economic gain in modern life.

But the field of alloy steels has by no means been fully exploited. The results which the steel maker has achieved with tungsten, molybdenum, chromium and vanadium, marvelous as they are, by no means mark the limit of the art. We now seem to be on the eve of still more important advances based on the use of new alloys, including ferro-uranium and ferro-zirconium. We hear whispers about a zirconium steel of 300,000 lb. tensile strength and 30% elongation. Not being a steel-maker and having no metallurgical reputation to lose, I may venture in my imagination to build an ocean liner or a freight train of this super-steel in which the dead weight is cut in half and the carrying capacity is increased 25%; or, I may visualize the super-steel bridge and finally the super-steel Pullman car, but in the latter case we are not so anxious to reduce the weight of the car and save steel. Rather we will make the super-steel Pullman four times as strong with the same weight of steel and then sleep soundly in the rear section of the rear car while the second section of the train follows one short block behind. Briefly stated, the job of the electrometallurgist is to put super-steel on a big tonnage basis.

Coal and Water-Power Resources.

Let us now consider our energy resources. These are fuel and water power, and their proper utilization will not only reduce the sum total of human toil necessary to run our industrial machine, but will be a measure of vital importance to coming generations. Our energy resources are necessary to the functioning of every other resource. They are at the very basis of industrialism, transportation and domestic well-being. Thus they concern society broadly, but they peculiarly concern the electrochemist because cheap electric power is a basic element in electrochemical production. The electrochemist was responsible for the success of the world's first great hydroelectric development, at Niagara, and became the natural champion of the utilization of our water-power resources. But why have we failed to sell this proposition to the man in the street and to those whom in his wisdom he has chosen to legislate for him? There may be many reasons for public indifference to coal economics and the waste of water power, but the fact remains that we have as yet failed to state the simple facts and principles of our energy economics in a way which carries conviction to the people with whom responsibility for action lies. Here are some of them:

1. Coal is our greatest energy resource. It is irreplaceable and, notwithstanding an apparent popular belief to the contrary, it is not inexhaustible. The amount available for present and future generations is known to be very definitely limited. The curve of consumption is rising regularly and rapidly, and we can compute with a fair degree of accuracy when our magnificent coal reserves will be exhausted.

2. Coal is wastefully mined, wastefully transported and wastefully utilized. If the bituminous coal used for domestic heating alone was first converted into artificial anthracite and the by-products recovered, it would represent a saving of more than twice our entire output of gold for 1917. If our railroads were electrified and fed from central stations recovering the by-products from the coal, this saving would be doubled.

3. Fuel and water power are practically interchangeable in industrial economics. The failure to use water power is just as truly a waste as would be the burning of our coal mines and oil wells. If Congress were to enact legislation to set the torch to one-third of all of our coal that was mined in the country last year, it would be no greater act of folly or crime than to obstruct water-power development. The utilization of water-power resources will save coal and oil for future generations and release for other useful work in the present generation hundreds of thousands of miners, vast transportation facilities and thousands of railway workers.

Having convinced the people that water power must be developed, the most difficult part of the problem remains to be solved, which is to arrive at a form of legislation in which the people and the capitalist believe that their respective interests are protected. Passing over the question of government ownership of water powers, I believe we must all now agree that no legislation for private development stands any chance of enactment which does not carry with it a very much larger measure of public control than would have been acceptable a few years or even a few months ago. Political ideas have changed, and one can plainly observe that public sentiment will not again consent to the development of its water powers as an unrestricted private monopoly. It would not so consent even when awakened to the great economic crime of letting them run to waste. After all, what we want is the power and I believe this Society cannot do less than endorse legislation in which public interests are fully protected by control of rates and proper limitations of charter rights. Following this, we want government surveys covering our complete energy resources and their utilization.

My conclusion shall be brief. It is plain that our science faces some of the big human problems of the day. Our opportunity for service was never greater, and I believe it will not be passed by.

SWISS RAILWAYS EXTEND ELECTRIFICATION OF THEIR LINES.

Further Particulars as to What Has Been and Is Proposed to Be Done.

In our issue of June 28 we published some data on Swiss railway electrification that appeared in a recent publication of the British Board of Trade. The following additional information has been kindly furnished by F. Dossenbach, director of the Official Information Bureau of Switzerland, 241 Fifth avenue, New York City.

The introduction of electric traction on the lines of the Swiss Federal Railways has in these latter years, on account of the acute shortage of coal occasioned by the war, received the foremost attention of the authorities and has now emerged as a very practical economic question.

The principal nerve of the Swiss railway system is Government-owned. Electrification of these lines is simplified by the vast store of unused water power which the country possesses. According to an official survey, verified in 1914, including the stowing and improvement of lakes, the water power of Switzerland is capable of producing an energy equal to 2,173,000 hp. If old plants were replaced by new ones, it is even estimated that the highest capacity of the total water-power reserves could be raised to as much as 8,000,000 hp. On January 1, 1914, the electric power already in use in Switzerland amounted to 887,000 horsepower.

The Swiss Confederation owns some 1800 miles of the entire railway system of the country, which covers 3216 miles. Of the 1416 miles owned by private companies 622 miles are already electrical, but only an insignificant percentage of the Government railroads has so far been operated by electricity.

The first important Federal standard-gauge road to be chosen for electrification was the Gothard Railway, one of the important international highways, and featuring, moreover, in many sections the brilliantly conceived engineering of mountain railways. The electrification of the 68 miles section Erstfeld-Bellinzona was approved in 1913 and it is expected that it will be opened this fall. This section, with

28% of its length consisting of tunnels and a grade of 2.5 to 2.7% for 25 miles, was chosen for an experiment because of its enormous traffic with Italy, which caused large consumption of coal with resulting smoke in the tunnels.

The sections Bellinzona-Chiasso and Erstfeld-Lucerne are expected to follow in 1921 and the consulting experts have found that the big power stations at Amsteg and Ritom, the first yielding 26,000 hp. and the latter 32,000 hp., will also suffice for these lines, even if the traffic should increase some 60 to 70%. Another series of plants yielding 70,000 hp. is planned for eastern and central Switzerland. The cost of electrification of the Erstfeld-Bellinzona line is estimated at $8,000,000. The cost of electrifying the entire Federal railway system is estimated roughly at $200,000,000.

In 1918 the electrification of the following railways using steam traction was decided upon and work on them commenced at once: The sections of the Federal Railroads Sion-Brigue and Berne-Thun; the section Hasle-Langnau of the Emmenthal Railroad and the section Bevers-Filisur of the Rhaetian Railroads. The section Sion-Brigue to be electrified will be a continuation of the electric line through the Simplon tunnel which was opened for traffic in 1906, with its northern exit at Brigue.

The electrified Berne-Thun line, connecting with the electric Berne-Lötschberg-Simplon railway, which latter was inaugurated in 1913, has already been opened for traffic in May last. It now provides excellent and frequent train connections between the Swiss capital, the Bernese Oberland resorts and—in connection with the Lötschberg line—the Valais and Northern Italy.

The new locomotives which are being used by the Swiss Federal Railroads on the section Berne-Thun, besides those of the Berne-Lötschberg-Simplon line, are each equipped with four single-phase alternating-current motors, each of 450 hp. All the electric parts were furnished by Brown, Boveri & Co., of Baden, and the mechanical parts by the Swiss Locomotive & Machine Co. of Winterthur.

Electrification work on the Bevers-Filisur line was completed by middle of last April and from April 16 steam engines have been duly replaced by electric motors, the current being supplied by the power station of Bevers, which furnishes the necessary energy for the Engadine lines that were electrified in 1913.

ALTERNATING-CURRENT EQUIPMENT ON NAVAL AND MARINE VESSELS.

Interesting Elementary Notes on Alternating Currents of Value to Electricians and Officers in the Naval and Marine Services.

Rapid developments in the use of electricity on shipboard have taken place in recent years. Formerly all electrical ship equipment was of the direct-current type and very seldom exceeded 125 volts. Recently the use of alternating-current machinery and apparatus has been introduced on naval vessels, which always have led in the use of electricity for a variety of purposes. In the July number of the United States Naval Institute *Proceedings*, Lieut Commander Lesley B. Anderson, U. S. N., states:

"There is no doubt that alternating currents have come in the navy to stay. At present they are applied to ship propulsion, radio, gyro-compass, submarine signaling, navy-yard light and power, and, on a smaller scale, to gun firing, three-wire generators, testing sets, magnetos, engine-speed indicators, and electric welding. There is such a large field for development that the use of alternating currents will probably be greatly extended within the next few years."

Since relatively very few naval or marine electricians are conversant with the subject of alternating currents, Lieutenant Commander Anderson gives in the article mentioned a simple and very clear outline of the main principles of alternating currents as they apply chiefly to the equipment being introduced for ship propulsion and radiotelegraphy. The article should be read by all interested in up-to-date electrical equipment on shipboard, if they wish to get a good conception of the important apparatus now already employing alternating currents. The notes included in the article were mostly explanations given to midshipmen and reserve officers, both in lectures and talks.

ELECTRIC SUPER-SUBMARINES DESIGNED BY BRITISH ENGINEER.

Designs for a new type of super-submarine have ben elaborated by Capt. Norman Wood, R. A. F., who recently read two papers on the subject before the Institute of Marine Engineers in London. Previous to his connection with the Royal Air Force, Captain Wood was engaged on submarine work and had practical experience of the deficiencies which exist in the design of even the latest vessels. On the surface submarines are driven by Diesel oil engines; under water they are driven by electricity from storage batteries which must be charged when the vessel is on the surface. These conditions are usually met by arranging the following chain: (1) Diesel engine, (2) clutch, (3) electric motor, (4) clutch, (5) propellor shaft. It is not difficult to see that this equipment involves a complex series of operations at critical times as, for instance, when the vessel is caught by an enemy searchlight when the batteries are being charged. Captain Wood proposes to simplify the transition from engine drive to motor drive (or *vice versa*) by adopting an all-electric drive, using, in a 1200-ton boat, two oil engines to drive electric generators supplying current to electric motors used on propellor ships, both naval and mercantile, on the ground that the growth of air power will render submersion the only means of escape from aerial attack. From this standpoint sea power will include air power and submarine power as well as strength in ships of the old type.

FRENCH NEWSPAPER URGES DEVELOPMENT OF WATER-POWER RESOURCES.

The *Echo de Paris* recently stated that the necessity of purchasing foreign coal might be relieved by developing the water power of France, which is estimated at 10,000,000 hp., as compared with 7,000,000 hp. for Norway, and 6,000,000 hp. for Sweden. Before the war only about 750,000 hp. was used, but a further 450,000 hp. was developed during the war, and by the end of 1921, 1,600,000 hp., or 16% of France's resources will be worked. This leaves a huge amount of water power in reserve and, in addition, there are large potential resources in the rivers of Indo-China and French West Africa. One million horsepower would lessen the consumption of coal for power production by at least 3,250,000 tons, costing about 300,000,000 francs, and the comparison is more striking when the greater average efficiency of the hydroelectric installation is considered.

Editorial Comment

Harmony in Conduct of a Meeting

EVERY association that amounts to a "tinker's damn" is bound to be confronted at times with problems over which a decided difference of opinion arises among the membership. On such occasions and by its handling of such problems the true caliber of the organization and the loyalty of its members are really shown. Such a condition arose in the spirited discussion of the labor problem at the Milwaukee convention of the National Association of Electrical Contractors and Dealers, and if any doubt existed prior to that time as to the real worth of this association it can now be dispelled.

It is not our intention to back either side in this issue in these comments as we believe that both sides had the best interests of the association at heart. When the members of any association are concerned in its welfare to the extent shown on this occasion and when the majority finally rules as was the case, there can be no doubt of the association's success.

The most impressive feature of this discussion, however, was the admirable way in which it was conducted and for this Chairman W. Creighton Peet deserves full credit. The position of the presiding officer is indeed a trying one in such situations and Mr. Peet is to be congratulated for the spirit of fair play, harmony and order that prevailed throughout the discussion because of the able manner in which he presided. A less calm and tactful chairman might have allowed such a discussion to get out of hand, leaving serious dissensions to develop that might disrupt an organization.

The Opportunities Before American Business

UNUSUAL opportunities are offered to American business and industrial interests to supply the many wants of war-stricken Europe and incidentally extend the period of recent prosperity. These opportunities have been pointed out by several leaders of industry. One of the most far-sighted views of the situation has been presented by Mr. Charles G. Du Bois, who recently became president of the Western Electric Co.; his clear statement is reproduced in this issue.

He shows that we are in much better physical and economic condition than nearly all other countries. The latter look to us to help them secure food and other much needed supplies. It is our opportunity as well as obligation to do this. But this involves a continuance of the intense industrial application that helped so much to equip and to keep our armies supplied. Recently there has been a relaxation of effort and the spread of industrial unrest, largely imported from bolshevist Russia, has led to countless strikes and other interference with production. What we need is stimulation of production. Idleness very seldom improves the prosperity of a country. The problem before us, therefore, is to redouble our efforts or else fail when the world is looking to us for help.

Similar ideas were also expressed recently by President F. J. Tone of the American Electrochemical Society, part of whose address is printed in this issue. He also emphasized the need for intensified production if the general welfare of the people is to be enhanced. We must make labor apply itself more or we must apply to it scientific and mechanical developments to make it more productive. It is to be hoped that both labor and capital will study the problem in the light of economic and scientific truth and by stimulation of production grasp the opportunities that now present themselves.

Strike Demonstrates Value of Traction Service

CHICAGO has been very seriously hampered and inconvenienced for a period (at the time this is being written) of fully four days this week due to a complete stoppage of all electric street-car lines and elevated railways in the city. When there was every prospect that the negotiations between the employes, the companies and the State Public Utilities Commission would lead to a fair and satisfactory solution of the controversy, the employes of the traction companies called a meeting that apparently was dominated by a small minority which refused to hear the report of the compromise offer and suddenly ordered a strike of all of the employes.

Although the threats of such a strike made during the preceding weeks had led to some efforts to provide emergency service in case the electric lines actually were tied up, the precipitate action of the employes in going on a strike at only a few hours' notice left the public in general entirely unprepared. All sorts of automobiles, motor trucks, buses, taxicabs, horse-drawn vehicles, motor boats, and even some airplanes were pressed into service; among these electric pleasure and commercial vehicles did their due share. The multitude of automobiles, suddenly rushed into the streets, was beyond the capacity of these arteries of travel and very many blockades and accidents resulted. The travel was uncertain, far from comfortable and considerable profiteering was resorted to, many persons being compelled to pay from five to ten times the ordinary street-car fare in order to reach their places of employment. The steam railroads, through increase of their suburban service, carried a considerable percentage of the persons compelled to travel to and from the central business district. Crosstown travel between outlying districts ceased almost entirely. An extremely large part of the city's two and one-half million inhabitants resorted to the ancient and wearisome method of traveling on foot.

Aside from the inconvenience to those who could not afford to lay off for the period of the strike, the business of the city suffered to the extent of perhaps millions of dollars due to a general slacking up of all work because employes could not reach business houses and factories at the usual hours and to a still greater extent because of the great falling off in business caused by difficulty on the part of purchasers in reaching stores and other places of business. The telephone company came to the rescue in this respect and as soon as it could get sufficient operators to the various exchanges did its utmost to speed up telephonic service. No figures are as yet available as to the enormous excess business carried on over the telephone, which if this means of communication had not been available would have left the city almost prostrate.

The entire city has through this strike again received a very positive demonstration of the extreme value of electric traction service, its low cost in comparison with substitutes therefor, and its indispensability to the business as well as social life of the community.

Responsibility of Utility Employes to the Public

NO EMPLOYE, nor any employer, can afford to ignore the interests of the public upon whose good will depends the success or failure of the business or industry that furnishes his sustenance. This simple truth will be generally accepted by the calm judgment of both workmen and business men. It applies alike to all lines of private business as well as to the quasi-public business commonly called public utility service. To the latter it applies with special force and directness, however, because the general public is so intimately concerned with the character and price of this service, as is shown by its assumption of regulatory control over public utilities.

In the early days of public utilities the importance of accepting responsibility to the public was not generally recognized. The usual attitude, in fact, was the very opposite as was so forcibly but tactlessly shown in the historic remark of a railroad capitalist of the last century—"The public be damned." These ideas ruthlessly carried out in such utility service as was rendered did not take long to stir up most vigorous public resentment. Not only were the utility corporations held in low esteem but they had imposed on them severe legal restrictions, from both of which many have not yet fully recovered. Nowadays, no manager of a public utility would think of committing business suicide by adhering to this obsolete and contemptuous policy.

It is strange, therefore, that this discarded attitude should be taken up by anyone connected with a public utility in any capacity. And yet on Monday evening of this week a meeting of employes of the electric street-car and elevated-railway companies in Chicago was disgraced by a small but vociferous element that drowned out the efforts of the calm and rational speakers by cries of: "To hell with the public." It is believed that this element with its radical or bolshevist ideas represents no more than 10% of the entire employes of these utility companies, yet it dominated the meeting and forced it to suddenly impose a strike on all the electric transportation lines of the city.

Some features of this strike are referred to in another column, and in our last issue we commented on the laudable efforts instituted by the Governor of Illinois to secure a peaceful and equitable solution to the controversy. There was every reason to believe that the compromise offer resulting from these efforts would be looked upon as not only fair, since it introduced better working conditions and wages than prevail in other cities in such service, but that it would be accepted. Yet the radical element referred to prevented deliberate consideration of the matter and brought odium upon all the organized employes by its contemptuous disregard for the interests of the public.

Quite early in this controversy this same element when presenting its extreme demands declared that it cared not where the funds required to meet them would come from, it was no concern of theirs, they knew what they wanted and were determined to have it. It was generally known that the companies were at the ends of their resources and any additional operating expenses would have to be met through increased fares. Moreover, the demands, if granted in full, would have required probably over 50% increase in fares with the inevitable result of greatly diminished traffic.

All these matters it was to be expected should have been given due consideration before the demands were first presented. Various evidences show that the public was little thought of, however. It is not necessary to dwell on other aspects of the case. One thing is certain, however. The strike that was called was entirely unnecessary and its effects will injure the men as much as the companies, if not more. The public has taken the inconveniences and loss due to the strike good naturedly, but it is showing little sympathy with the arbitrary attitude of the men. A very considerable number of passengers have been lost to the traction lines permanently. It is time that the men realize it is folly to kill the goose that lays the golden eggs. Contempt for the interests of the public has never paid to utility capitalists nor will it pay to utility employes.

Current Events

New N. E. L. A. Administration Begins Work—Improving Industrial Relations—Frederick Sargent Passes Away

NEW ADMINISTRATION, N. E. L. A., GETS DOWN TO WORK.

Considerable Activity Shown by Reports Presented at First Meeting of New Executive Committee.

The first meeting of the Executive Committee of the new administration of the National Electric Light Association was held at the association's headquarters, New York City, on July 10. In the absence of President Ballard, Vice-President Martin J. Insull presided.

On motion Everett W. Burdett was re-elected as general counsel. The following committee chairmen were also appointed: Accident Prevention, Charles B. Scott; Company Sections, Frank A. Birch; Constitution and By-Laws, W. C. L. Eglin; Doherty and Billings Prizes, A. S. Loizeaux; Exhibition, C. L. Pierce, Jr.; Finance, Joseph B. McCall; Lamp, Frank W. Smith; Membership, Walter Neumuller; Class C Membership Applications, Walter Neumuller; Public Policy, John A. Britton; Rate Research, Alex Dow; Relations with Educational Institutions, John F. Gilchrist; Safety Rules, W. C. L. Eglin.

A letter from President Ballard was read outlining plans for the year's work, and suggesting the following subjects which might be considered: Electrical resources of the Nation, electrification of steam railroads, rules of regulatory bodies, public information, employes' participation.

In connection with the subject of electrical resources of the Nation, the committee called attention to the fact that both the Department of the Interior and the War Industries Board have compiled considerable data relating to this question and that it might be well to appoint a committee to bring together all of the data and material on the subject collected by different bodies and put them in shape for the central stations to use.

It was announced that the Technical Section had reappointed the Committee on Electrification of Steam Railroads, which was discontinued several years ago, and that Peter Junkersfeld would serve as chairman. Mr. McClelland stated that statistics as to the savings effected by electrified roads should be collected and publicity given to them. It was also suggested that a National Committee might be appointed on this subject to work in conjunction with the Technical Section Committee.

Mr. McClelland advised that the National Industrial Conference Board has been doing a great deal of work on the subject of employes' participation, and that if the Association appoints a committee to study this question it should utilize the data collected by the Board.

President Ballard's letter regarding the year's work also covered the representation of the Association at all Geographic Section and other electrical conventions.

Chairman Moultrop, of the Technical Section, reported that his Executive Committee had held an all-day meeting on July 9, at which time the committees were appointed, the work of each outlined and their meetings scheduled for the next 12 months. In order to enable the western committee members to attend, the meetings will be held as far west as possible, one or two being scheduled for Denver. By the appointment of O. B. Coldwell, of Portland, Ore., as a member of its Executive Committee, the Technical Section now has a representative from both the northwest and the southwest, H. A. Barre, of Los Angeles, also being a member.

Mr. Moultrop reported that in compliance with a request received from R. S. Hale, chairman of the Wiring Committee, he is arranging for technical representation on that committee. He also reported that the Committee on Overhead Lines and Inductive Interference has been divided into two committees, with W. K. Vanderpoel chairman of the Overhead Systems Committee, and A. E. Silver chairman of the Inductive Interference Committee.

At the suggestion of Vice-President Bump, the following committee was appointed to make a report to the Executive Committee at its next meeting on a definite division of the states into Geographic Sections: Chairman R. J. McClelland, H. E. Brandli, J. E. Davidson, L. D. Gibbs, Robert Lindsay, E. W. Lloyd, O. H. Simonds and F. M. Tait.

Acting Secretary Sewall read a report on the work of the Company Sections and the plans of the Company Sections' Committee for the year, which report was prepared by Vice-President Johnson and also the report of the Committee on Managing Director, which stated that the committee considered it necessary that such a director be appointed.

Chairman Symes of the Accounting Section reported that one meeting of his Executive Committee had been held at which time the committees for the year were considered and some of the less active ones discontinued. The Committee on Accounting Relations with Other Associations was merged with the Committee on Classification of Accounts, and the Committee looks for marked progress in the national standard classification of accounts. He also reported that four new committees had been added: Bonus System, Federal Income Tax Return Procedure, Credits and Collections, and Insurance.

For the Commercial Section, Chairman Learned reported activities are well under way and the committees have been appointed, some of which are already functioning. The general plan is to handle the work of the Section as formerly with the addition of the following two new committees: Committee on Relations with Geographic Sections, Company's Sections and State Electric Associations, and Committee on Relations with Contractors, Dealers and Jobbers. It is planned that representatives of this latter committee will attend all state and national meetings of contractors, dealers and jobbers. This plan has already been put into effect.

For the Electric Vehicle Section, Chairman Foster reported that the Section was considering appointing an advertising man, but that if a publicity man were engaged for the Association this might not be necessary. Mr. Foster stated that as a result of some recent co-operation in Chicago the electric garages have been able to effect considerable saving in insurance premiums and have also been made agents for the insurance companies, thus enjoying commissions on this work. He reported that the Transportation Engineering Committee is now conducting correspondence with 155 colleges in the matter of developing further transportation engineering courses and is compiling a list of electric truck users to which questionnaires are to be mailed to secure operating cost data, etc.

Mr. Foster also spoke of the indifference of central station employees toward the electric vehicle, and said that it was hoped to overcome this feeling by the publication of articles in the Association's *Bulletin* and other ways. He also mentioned the great benefits that might be derived from what he styled a spectacular campaign to introduce electric vehicles, suggesting the possibility of selling them to some city for use in its departments generally, with the particular object of giving wide publicity to such a sale.

John A. Britton, vice-president and general manager of the Pacific Gas & Electric Co., San Francisco, a regent of the University of California and one of California's most prominent citizens, has been appointed by President Ballard, chairman of the Public Policy Committee. W. W. Freeman has been appointed vice-chairman.

SPRAGUE SHOP COMMITTEE DECIDES ON THRIFT AMONG EMPLOYES.

General Shop Committee of Sprague Works of General Electric Co. Adopts Thrift Bond Savings System.

An interesting example of the actual working of the "shop committee" in industrial plants was afforded by a meeting of the General Committee of the Sprague Electric Works of General Electric Co. at Bloomfield, N. J. In the organization of the plant there are committees covering each of the various shop activities and the General Committee, which is composed of these subcommittees and consists of about 35 employes.

The meeting was called to consider the question of making thrift among the employes permanent—a subject receiving increasing attention in industry because of the stabilizing effect of thrift on the workers and the big impetus given to thrift by the war which threatens to be lost.

The committee decided unanimously that regular saving makes for the well-being and contentment of the worker. Various methods of saving were discussed, including savings banks, building and loan associations, War Saving Stamps and the Thrift Bond savings system. The committee did not favor methods involving periodical deposit of money or the purchase of securities because of inconvenience, difficulties of withdrawal and irregularity. The committee unanimously decided in favor of "automatic saving" through pay-envelope distribution. This is the principle of the Thrift Bond savings system installed by the National Thrift Bond Corporation, New York City, for the General Electric Co.

In this system the employe signs a subscription form promising to save a certain amount regularly and thrift receipts to that amount are inserted in his pay envelope instead of cash. The saving is thus automatic and requires no further initiative on the part of the worker. Ten dollars' worth of these thrift receipts may be exchanged for a $10 Thrift Bond, which bears interest paid through coupons attached. Ten of these Thrift Bonds may be exchanged for a $100 registered Thrift Bond. Taking up the question of continuous encouragement of the idea among the employes, the committee disapproved of solicitation by volunteers in the works' organization and preferred the work being carried on by paid agents of the banking corporation.

According to the executives, the opinions of the employes' committee were of value, because in such cases best results are obtained by using methods endorsed by the workers.

PROGRAM FOR AMERICAN ELECTRO-CHEMICAL SOCIETY MEETING.

Fall Meeting to Be at Chicago, Sept. 23-26 and Include Joint Session With American Institute of Mining and Metallurgical Engineers.

The fall meeting of the American Electrochemical Society is to be held at Chicago on the four days, Sept. 23-26. Headquarters will be at the Congress Hotel. The tentative program calls for four joint sessions with the American Institute of Mining and Metallurgical Engineers, which will hold its convention at the same time and place. At present the tentative program is as follows:

Tuesday, Sept. 23: Excursion by boat with American Institute of Mining and Metallurgical Engineers to Gary, Ind., and trip through United States Steel Corp.'s plant. Joint technical session, on the boat, returning from Gary, subject: Electrometallurgy of Iron and Steel. Joint technical session, at Congress Hotel in evening at 8:30 p. m.

Wednesday, Sept. 24: Morning—Session for reading and discussion of papers. Afternoon—Joint Ferrous Metals. Evening—Inspection of the electric furnace exhibits at the Chemical Exposition.

Thursday, Sept. 25: Morning—Symposium of Catalysis. Afternoon—Symposium of Catalysis, continued. Evening—Smoker and entertainment.

Friday, Sept. 26: Morning and afternoon—Joint session; subject: Symposium on Pyrometry.

The secretary of the Society is Prof. Joseph W. Richards, Lehigh University, Bethlehem, Pa.

ACTIVE WORK PLANNED BY OVERHEAD SYSTEMS COMMITTEE, N. E. L. A.

Committee Seeks Co-operation of Member Companies' Engineers and Others in Bringing All Overhead Line Data Up to Date.

The Overhead Systems Committee of the National Electric Light Association, formerly called the Overhead Lines Committee, desires the co-operation of all members and member companies in this year's work of the committee. It plans to bring up to date the descriptions, specifications and other matter previously published relating to overhead line construction. Information will be compiled regarding recent experience and new practices, with especial attention to any innovations and other features developed during the war period.

To make this work complete, the committee needs active assistance, and it would be much appreciated if members will communicate freely with the committee, furnishing any information which would be useful to the industry. Members are also invited to suggest any features which they think should be developed in the next report. Matter of this kind should be presented in sufficient detail so that the committee can work to the best advantage in securing the desired information.

It is suggested at this time that the previous reports of the committee be reviewed by members in order to determine the character of the recommendations and information still required. If such attention is paid to this subject, the committee's activities will be guided by the real necessities of the industry and there will be a greater production of valuable construction data, without repetition of information already available.

It is hoped the work of the committee will not only be facilitated by these contributions; but that members will avail themselves of this opportunity to make use of their committee by indicating the kind of assistance they desire.

W. K. Vanderpoel, superintendent of the Public Service Corporation, Newark, N. J., is chairman of the Overhead Systems Committee.

MAY ELECTRICAL EXPORTS MAINTAIN HIGH LEVEL.

Monthly Total Only Slightly Below March Record—Eleven-Month Aggregate Is Nearly $70,000,000.

Another high monthly total in electrical exports has been recorded in the figures for last May which have been made public by the Bureau of Foreign and Domestic Commerce, Washington, D. C. The electrical shipments from the United States for that month totaled $7,717,518, or only 2% below the record set last March. The May total was a few thousand higher than that of last April and it was also nearly 54% higher than May of last year.

In the following table are given the detailed figures for last May and the corresponding month of 1918:

Articles.	May 1919.	May 1918.
Batteries	$ 516,001	$ 308,895
Carbons	130,982	112,902
Dynamos or generators	257,908	443,351
Fans	201,125	120,980
Heating and cooking apparatus	146,765	48,492
Insulated wire and cables	838,188	344,186
Interior wiring supplies, including fixtures	179,931	140,050
Lamps—		
Arc	1,300	1,085
Carbon-filament	44,157	10,459
Metal-filament	434,894	308,908
Magnetos, spark plugs, etc	291,415	160,395
Meters and measuring instruments	245,589	161,431
Motors	817,118	574,437
Rheostats and controllers	64,478	28,516
Switches and accessories	255,099	148,359
Telegraph apparatus, including wireless	70,296	32,339
Telephones	285,785	251,785
Transformers	326,224	214,958
All other	2,610,263	1,601,920
Total	$7,717,518	$5,013,379

The above figures do not include electric locomotives, of which there were exported last May five valued at $37,000. For the first 11 months of the present fiscal year—that is, for the 11-month period ended May 31, 1919—the total electrical exports aggregated $69,698,590, as against $49,527,442 for the corresponding period ended May 31, 1918, and $46,323,381 for the similar period ended May 31, 1917.

GOVERNMENT RETURNS WIRE LINES TO COMPANIES.

Postmaster General Burleson Expresses Satisfaction Over the Manner in Which Government Has Controlled Telephone and Telegraph Facilities.

On order of Postmaster General Burleson government control over telegraph and telephone systems of the country ceased at midnight, July 31. In his statement to the public, Mr. Burleson said he is satisfied with the result of government control, despite widespread public criticism of the telegraph and telephone service for more than a year.

The order of release directed that all telegraph and telephone systems and all property thereof taken over by order of Congress July 16, 1918, be "returned and delivered to the respective owners thereof at midnight on July 31, 1919, and the supervision, possession, control and operation exercised by the postmaster general will cease at that date and hour." The order further directed how outstanding accounts of government operation are to be settled with William H. Lamar, chairman of the Finance Committee of the Wire Control Board, and gave instructions for closing up relations between the Government and the companies.

"With the issuance of Order 3380, providing for the auditing and accounting division," Postmaster General Burleson said, "the first government control of the wire systems of America is brought to an end. Sound public opinion will ultimately demand how this trust has been met, and the Postmaster General is content to abide the result.

"The Postmaster General desires to express to the officers of the telephone and telegraph companies grateful appreciation of the uniform co-operation given during the period of government control."

CHEAPER ELECTRIC WIRING PROPOSED IN ENGLAND.

Committee Formed to Consider Whether Relaxation of Standards Is Justified.

A special committee of the Institution of Electrical Engineers (Great Britain) has been formed to consider the revision of the existing rules for electric wiring in buildings. This committee is the outcome of a growing conviction that the high quality of British cables and accessories justifies a relaxation of the standards hitherto imposed. During the war an enormous number of army buildings have been wired on the surface and in other ways not consistent with standard British practice, and the experience thus gained will be turned to account in cheapening the cost of installation and materials. British manufacturers of wires, switches, insulators and other accessories will thus be led to expand the production of types which will be peculiarly adapted to meet the needs of the overseas markets. Satisfactory quality will be insured by the National Electric Provng House which is about to be established in Great Britain. The Proving House will put the standard of good design, material and workmanship on every class of electrical apparatus, thus giving British productions the full benefit of the high reputation they have always held.

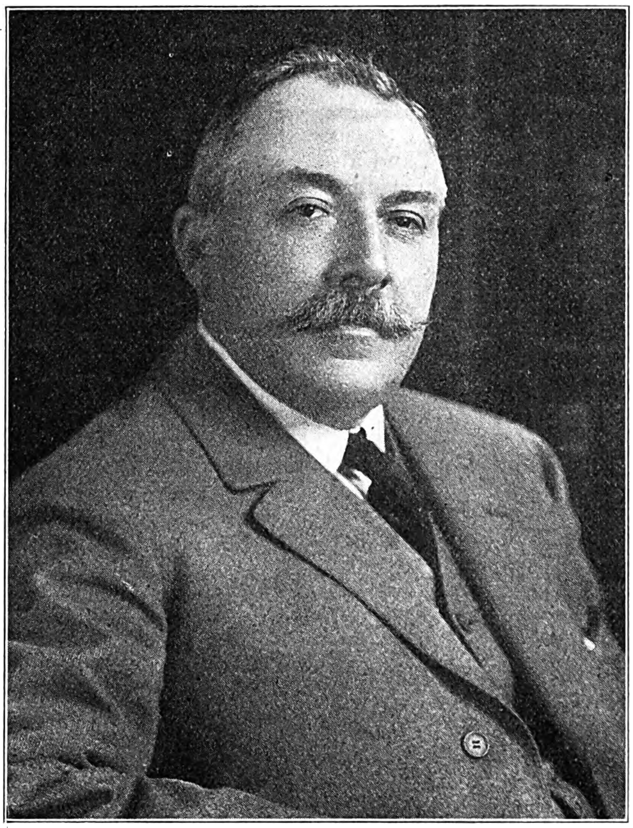
As all attempts made thus far to cheapen wiring in this country have met with disfavor the results of the British committee's investigations will be watched with interest.

FREDERICK SARGENT, PROMINENT POWER ENGINEER, IS DEAD.

Famous Engineering Career in the Design of Large Power Stations Brought to a Close.

Frederick Sargent, senior member of the firm of Sargent & Lundy of Chicago, and probably the most prominent consulting engineer in the United States specializing in the design of electric generating stations, died at his home in Glencoe, Ill., early in the morning of July 26. An Englishman by birth, Mr. Sargent had made numerous trips to his native country and on one of these, made in April and May of this year in company with his close friend, Samuel Insull, president of the Commonwealth Edison Co., Chicago, he was taken seriously ill while abroad. On his return he was removed to a hospital but the doctors were able to do but little for him, and he was taken to his home, where the end came.

Frederick Sargent was born in Liskeard, Cornwall, England, on Nov. 11, 1859, which is also the exact date of the birth of Samuel Insull, also an Englishman and Chicagoan, with whom Mr. Sargent was destined to be intimately associated during practically all of his engineering activities. His people were of the farming class but young Sargent developed a decided mechanical bent, and eight years of his boyhood and youth were spent in acquiring practical mechanical knowledge and experience in the works of John Elder & Co., the great shipbuilders on the River Clyde, near Glasgow. During this time he gained an extensive and practical knowledge of mechanical engineering, paying particular attention to heavy machinery. The young engineer also improved his education at this time by going to night school at Glasgow University.



Frederick Sargent.

Coming to the United States about 1880, the young man found ready employment in eastern shipbuilding yards as a designer of steam engines. He then came west as a designer for the Sioux City Engine Co. of Sioux City, Iowa. A year or so later he accepted a position with E. P. Allis & Co., engine builders of Milwaukee, predecessors of the present Allis-Chalmers Manufacturing Co. Here he attracted the attention of the officers of the Western Edison Light Co., organized in Chicago in 1882 to exploit the electric lighting inventions of Thomas A. Edison in the West, and in the fall of 1884 Mr. Sargent came to Chicago and began his career as an electrical engineer in this city.

Succeeding the Western Edison Light Co., the Chicago Edison Co. was formed in 1887, the first distinctively Edison central-station company in Chicago. Mr. Sargent became its consulting engineer and he has been consulting engineer of that company and its successor, the present Commonwealth Edison Co., ever since.

About 1889 Mr. Sargent went to New York under contract with the Edison United Manufacturing Co. In this position he had general charge of all the work done by that company in the United States and Canada. Shortly after this, the company in New York was reorganized as the Edison General Electric Co., and the subject of this sketch was made assistant chief engineer of the new corporation of which Samuel Insull was vice-president in charge of manufacturing. But Mr. Sargent had determined to open an office of his own, and in August, 1890, he returned to Chicago to establish himself as an independent electrical and mechanical engineer. The firm of Sargent & Lundy was formed in 1891.

In 1891 and 1892 Mr. Sargent was consulting electrical engineer for the World's Columbian Exposition of Chicago, and he designed the power plant and had much to do with the other mechanical and electrical features of the great World's Fair of 1893.

The original Edison central station in Chicago was at what is now 120 West Adams street, and was built in 1887 and 1888. Mr. Sargent made the plans for the machinery layout of that station. In 1892 Samuel Insull came to Chicago as president of the Chicago Edison Co., and that company at once took on a new lease of life. Under Mr. Insull's direction the old Harrison street generating station was built in 1893. Mr. Sargent was the designer of that station, also the Fisk street, the Quarry street and the Northwest generating stations of the Commonwealth Edison Co.

Mr. Sargent was one of the first electrical and mechanical engineers who recognized the great part that the steam turbine was destined to play in the development of electric generating stations. The Fisk Street station was the pioneer of all the large turbine central stations of the world and it became deservedly famous for its many original features of design and for the simplicity and economy of operation. After this station had been in operation for a short time Mr. Sargent was sent to London as a representative of the United States on the hearing in Parliament in connection with the London power-supply bill. This hearing crystallized in Mr. Sargent's mind some ideas he had been developing about the importance of unified power supply for great industrial centers so as to reduce the cost of production, and on his return he submitted his ideas to Mr. Insull and they were worked out in the power-station development of the Commonwealth Edison Co.

Mr. Sargent's engineering work, however, was not confined to Chicago. He was consulting engineer for many of the important electric light and power companies throughout the country, including the Edison Electric Illuminating Co., Boston; American Gas & Electric Co., New York; Electric Bond & Share Co., New York; the Union Gas & Electric Co., Cincinnati, as well as many other smaller organizations. He designed the great combined central power station of the American Gas & Electric Co. and the West Penn Power Co., located on the Ohio river north of Wheeling, W. Va., which is the first large electric station to be built in a favorable locality near a coal mine for the distribution of power to industrial centers at long distances. He designed the new station of the Union Gas & Electric Co., at Cincinnati, which has recently been completed. He also designed the new station for the Kansas City Light & Power Co., which is soon to be put into operation. He went to Chile in 1916 as consulting engineer for the Guggenheim mining interests on the development of a power supply for their mine at Chuquicamata. During the recent war Mr. Sargent was consulting engineer for the power station at the Edgewood Arsenal at Edgewood, Md., and also consulting engineer for the United States Government in other war-time projects demanding the application of power on a large scale.

The decedent was awarded a medal by the World's Columbian Exposition in 1893. He was also a member of the jury of awards in power engineering at the St. Louis Exposition of 1904. He was a member of several societies and clubs, including American Society of Mechanical Engineers, Western Society of Engineers, University Club, Chicago Yacht Club and Skokie Country Club, and Engineers' Club of New York.

Mr. Sargent was married to Miss Laura S. Sleep at Sioux City, Iowa, in 1885. The widow, one daughter, Miss Dorothy Sargent, and two sons, Chester Sargent and Ralph Sargent, survive.

In his profession Mr. Sargent was noteworthy for the clear vision and strong common sense with which he grappled with the essentials of an engineering problem. He was simple, clear, direct and practical. He was a man of broad outlook, tolerant, modest, seeking results rather than to uphold theories. And he was eminently successful in obtaining results, for his electrical generating stations were milestones of achievement in the economical production of electrical energy. He stood in the front rank of those men whose efforts have made electricity cheap for the people—an everyday necessity in the home and factories of the United States.

An idea of the esteem with which Mr. Sargent was held by his business associates was shown in an interview with Wm. S. Monroe, his friend and partner in business for many years, who said:

"Mr. Sargent had an exceptionally keen and active intellect and a vigorous and forceful personality. He was a man of absolute integrity and fearless independence and high idealism in his work. He had an infallible intuition regarding engineering and scientific matters, and the responsible men in the companies for which he was doing his engineering learned to place the utmost confidence in his judgment. He had a remarkable combination of extreme daring and careful conservatism. With a broad and ambitious view of important and fundamental principles of his engineering work, Mr. Sargent combined an accurate knowledge of all the underlying details, and no detail was too small for his personal attention.

"He kept in close touch with everything that was new in the engineering profession. He was a great traveler and made repeated trips to Europe as well as through this country in order to post himself on the important developments—not only in the direct line of his own work but in all departments of the engineering field.

"His idealism was at times almost prophetic and he was very ambitious for the highest achievements in his work, but his idealism was held in restraint by a practical common sense judgment, which combined to give a distinct originality to every new power station which he designed, and made it systematic and harmonious, economical and a perfect working machine."

Samuel Insull, for whom Mr. Sargent did most of his important work, held his engineering ability in high estimation. In a speech delivered in December, 1911, Mr. Insull spoke of Mr. Sargent as "at the head of his profession, the electrical engineering profession, in this community, and the designer of our wonderfully economical central stations." In many other speeches he also took occasion to praise Mr. Sargent and his ability.

A large number of messages, further evidence of the esteem in which he was held by his associates and friends, was received by Mr. Insull and the family from men prominent in the electrical industry and the engineering profession among whom were the following: C. A. Coffin, J. B. McCall, Guy E. Tripp, E. W. Rice, Jr., and J. W. Lieb.

SURVEY ON PLANS FOR IMPROVING INDUSTRIAL RELATIONS.

National Association of Corporation Schools Issues Statement on Results Achieved in Various Industrial Organizations.

To what extent the readjustment of working conditions in the industries of the United States is giving the workers a voice in management at the moment is difficult to determine. The effort to democratize the industries is making steady progress, but so far results are not conclusive.

The National Association of Corporation Schools, with headquarters in New York City, is studying the problem of a more equitable distribution of created wealth through industrial pursuits, and also attempting to eliminate present wastes due to lockouts, strikes and other forms of industrial strife, through scientific employment, training of the industrial workers and other personnel problems. This association, in which some 133 of the larger industrial institutions of the United States have membership, including prominent electrical utility companies, advises that a recent inquiry among several hundred industrial corporations reveals that there are three plans that are being used, all designed to give employes more voice in management, especially as relates to working conditions, hours and wages. The results of the inquiry indicate that a considerable majority of the larger industrial institutions have either inaugurated some one of the three plans or are studying the various plans and gathering data on results so far obtained, with a view to determining which of the plans they will inaugurate.

These three plans are known as the "Works' Committee" plan, the "Industrial Council" plan and the "House and Senate" plan. The purposes of the three plans are practically the same, but the method of operation differs. So far as known, none of these plans involves direct representation on the part of the workers on the board of directors. However, it is anticipated, if it is found as a result of experiments that employes assume the responsibility, which logically they must assume if they are to have a continuing voice in management, that ultimately employes will be permitted to name a minority representation upon the board. Such action probably will occur only in industrial institutions where a considerable number of employes are stockholders, and the representation which they secure upon the board of directors will be dependent upon the amount of shares of stock represented by the employes who have a right to vote for such representation.

In one of the largest industrial institutions, where the "industrial council" plan has been made effective, the immediate result was a request on the part of the employes' representatives in the industrial council for an increase in wages and shorter working hours. This was followed by an avalanche of requests from individual employes for increases in wages. When it was pointed out to the representatives of the employes by the members of the industrial council representing the stockholders and management, that such action would necessarily involve an increase in the cost of the product of the company, and that this increase would bring the selling price of the company's product to a figure considerably higher than the selling price of its competitors, the request for shorter hours and increased wages were temporarily, at least, withdrawn. In other words, the immediate results of giving a voice to employes through delegated representatives were wholly selfish and not based upon investigation as to conditions, and were made without any assumption of responsibility whatsoever.

In at least three large industrial institutions where some one of the three plans has been introduced, strikes have followed within a period of one month. In other companies the plans have worked well, although the period of trial is of too short duration to admit of any conclusions as to what will be the final results and as to what definite attitude the representatives of employes may ultimately take. The assumption may be safely made, however, that employes of industrial corporations will continue to demand a voice in those problems of management which affect wages, working conditions and hours of labor. Whether or not the representatives of the workers in industrial councils will assume a fair portion of responsibility remains to be determined. So long as shorter hours and higher wages can be secured through strikes, it is probable that the new co-operative plans will make slow progress, but when the time arrives, as it inevitably must arrive, that strikes are no longer so successful, and when the public will demand to be heard in the settlement of wage disputes, it is believed that more constructive progress can be made in the working out of co-operative management, and that the workers will then assume a more definite responsibility for production. It is obvious that responsibility must be assumed by the workers if the industries of the United States are to be placed upon a more democratic or co-operative basis. Efforts to introduce better training systems and more scientific employment methods are meeting with no opposition and are progressing steadily. Also, efforts to encourage thrift (to include home owning), group insurance and sick and death benefit features are meeting with encouragement.

The survey also disclosed that plans to insure stock ownership by employes in the company by which they are employed are rapidly becoming installed, the number of companies now installing this feature being far in excess of the number that were working on similar plans prior to the reconstruction period. Stock-ownership plans almost invariably include provision for service annuities or retirement pensions.

The belief expressed by Judge Gary, chairman of the United States Steel Corp., that efforts to unionize the employes of the various subsidiary companies of that corporation would not succeed because the men realize they are better off under "open shop" conditions than they would be under the control of unions, is assumed by many other industrial executives. In fact the present effort is not only to secure employe or co-operative effort in management, with proportionate responsibility, but also to provide conditions whereby the workers of the larger industrial institutions will receive a greater degree of advantage than would be possible under the customary unions' control and direction.

The crux of the situation seems to be acceptance of responsibility by the representatives of the workers for greater output commensurate with shorter hours and higher wages.

FORTHCOMING MEETINGS OF THE AMERICAN INSTITUTE.

Dates of Pacific Coast Convention and Other Meetings Announced.

Pacific Coast Convention.—The Pacific Coast convention of the American Institute of Electrical Engineers will be held September 18-20, 1919, at Los Angeles, Cal., under the auspices of the Los Angeles Section.

New York Meeting.—A joint meeting with the Institute of Radio Engineers will be held in New York City on October 1, 1919. The subject of this meeting will be Radiotelegraphy.

Philadelphia Meeting.—On October 10, 1919, a regular meeting of the A.I.E.E. will be held in conjunction with the American Physical Society. This meeting will be under the auspices of the Electrophysics Committee.

New York Meeting.—A regular Institute meeting under the auspices of the Power Stations Committee will be held in New York City on November 14, 1919.

CHICAGO CONTRACTORS HOLD ENJOYABLE OUTING.

The Chicago Electrical Contractors' Association held an outing at the Olympia Fields Country Club on July 30 which proved to be one of the most enjoyable affairs ever conducted by this association. On this occasion the members and their guests competed in numerous athletic events, the most interesting of which were the golf tournaments. Many valuable prizes were presented to the winners of these contests and tournaments.

In addition to the members, there were present representatives from practically every branch of the industry who took a prominent part in the events.

Commercial Practice

Review of Electric Range Handbook—Priority in Event of Service Curtailment — Rates for Service Extensions

NEW HANDBOOK CONTAINS VALUABLE INFORMATION AND DATA.

Brief Review of "Electric Range Handbook" Published by Society for Electric Development.

The Electric Range Handbook prepared and published by the Society for Electrical Development, United Engineering Societies building, New York City, is a complete compilation of authentic information and data on this electrical appliance. As the rapidly growing interest in electric cookery, and the many advantages that electric cooking apparatus offers as a load builder have made the electric range one of the most important and prominent factors in the industry at the present time, the value of such a book can readily be appreciated.

It consists of 208 pages, attractively illustrated, bound in flexible leather, and is dedicated "to the national conservation of fuel, food and labor and to greater efficiency and economy in the home."

Its purpose is to guide and assist central-station managers who have realized the importance and profit of the electric range load and are contemplating the establishing of a special service rate and the merchandising of ranges. A secondary purpose is to stimulate greater range activity in general and to show the way to more extensive sales to manufacturers, jobbers and contractor-dealers.

The information and recommendations are based on the experiences and policies of a number of central stations which have pioneered and placed the sales and service of the electric range on a definite, successful and profitable basis. The text has been reviewed and approved by range authorities and cannot be materially affected by changing conditions, as the fundamental methods of merchandising and maintaining this load builder will remain unchanged.

In the first chapter the fundamental facts concerning the electric range are stated. Its value and desirability as a load to central stations are clearly shown and compared with other household appliances, followed by a general discussion of the advisability of establishing special rates for such service and the justification of such rates as shown by public service commission rulings. In addition, the various methods of financing extensions for such service that have been developed by many companies are reviewed and a valuable collection of data from 100 central stations is presented.

In the second chapter the modern electric range, its practicability and supremacy, construction and price, operating cost and economy, and its many advantages when used in the home are described. In addition, kitchenette ranges, which are in considerable demand for smaller and more compact apartments, and the many ingenious methods of installing them are also shown.

The third chapter is devoted to electric cookery, its development, advantages, characteristics, methods of application and principles, while the fourth chapter is a study of the desirability and advantages of the range load and its characteristics.

Chapter five explains the methods of installation with special attention being given to the methods of determining the proper size of conductor and the necessary wiring connections.

Chapters six, seven and eight are devoted to the merchandising of electric ranges and are entitled: merchandising methods, selling points, and advertising, respectively. Each of these chapters contains a fund of information on its particular subject and should prove of great assistance to the central-station manager and salesman in the conduct of their range business.

Service and maintenance are the subjects discussed in chapter nine. Selling a range, it is explained, is 10% salesmanship and 90% service and there are four divisions to this service: buying service, installation service, current service and maintenance service. The advantage of educating the new user in the proper methods of range operation and its fundamentals is also shown.

Every company attempting to encourage the use of electric ranges is confronted with the problem of heating water electrically in conjunction with the range and for this reason the various types of water heaters, their advantages and application are described in chapter ten.

Commercial cooking and the heavy duty apparatus designed for this apparatus are described in chapter eleven, while the final chapter consists of a compilation of general information on the subject.

The book is being sold by the Society for Electrical Development for $1.50 per copy and at least one prominent electric range manufacturer has purchased a supply which will be distributed in connection with its sales work.

COMMISSION RULING GOVERNS PRIORITY IN SERVICE CURTAILMENT.

Public Service Commission of Missouri Includes This Important Feature in Recent Decision.

The ruling of the Public Service Commission of Missouri in its proceeding against the St. Joseph, Light, Heat & Power Co. of St. Joseph, Mo., recently, brought out one especially interesting and important provision governing the conduct of such combined utilities. This provision states the priority to be given in the rendition of the different classes of service such as electric service, heating service and the street railways in the event of an occasion arising which prevents the rendering of all three classes. This ruling is particularly significant at the present time as many authorities predict a serious fuel shortage during the coming winter which may bring some utilities face to face with extreme conditions that demand a curtailing of service.

The proceeding was instituted by the commission to determine whether the service rendered to the public by the company was adequate and sufficient. The company conducts a combined plant supplying electric service and heat, and operating the street railways of the city.

According to the evidence it was found that the service until early in 1918 had been entirely adequate. At this time an interruption occurred due to failure of some plant equipment. This failure was remedied and no further trouble was experienced until Jan. 2, 1919, when a failure in the local water supply, caused by an ice gorge, required the complete suspension of the operation of the plant. An emergency pipe line was run to the river to overcome this difficulty but due the large amount of sand and gravel in the river water which clogged the boiler feed-pipes and pumps and resulted in low water in the boilers and the blowing out of boiler tubes, the interruptions to the service still continued.

The commission therefore ordered the company to provide additional equipment as a precaution against such failures in the future and also to provide a sufficient auxiliary water supply, independent of the city water supply, for boiler feed purposes.

The commission also ruled that in the event it became necessary to curtail the service in the future, priority shall be given as follows:

"A.—Steam-heating service, except during the morning and evening rush hours of the street railway service.

"B.—The street railway service in general.

"C.—The lighting service.

"D.—The power service.

"Before cutting out the power circuits, the company shall notify the power users for such reasonable time in advance as may be necessary to prevent undue amount of damage."

The commission also made the following statement relative to the efficiency and ability of the company's organization: "It is only fair to state in connection with the investigation that the manager and the supervising engineers are thoroughly competent and are making every effort to restore adequate service."

In conclusion, the finding states:

"The Commission has recently authorized a general rate increase for the various public services rendered by the defendant company. This increase has been granted upon the assumption that the service rendered was then and would continue to be fully adequate and sufficient. A continuation of inadequate service to the public may necessitate further consideration by the Commission of the reasonableness of the present rate schedules, since the charging of just and reasonable rates must be accompanied by the rendition of adequate and satisfactory service."

Commission Also Permits Company to Discontinue Service.

The commission, feeling that the broad and comprehensive powers conferred upon it necessarily imply the power to relieve a utility from rendering service where the facts warrant such action, also delivered a decision permitting the Marshfield Electric Co. of Marshfield, Mo., to discontinue operation at the end of a six-month period. The evidence in this case showed that the company was operating at a decided loss and that an adequate rate increase would not remedy this condition.

The real difficulty at Marshfield appears to arise because of the small proportion of citizens using electricity. While the city has a population of about 1500 and approximately 300 homes, there are only 190 connected consumers. An increase of rates would certainly not tend to increase the number of consumers but would reduce the number of present consumers and the quantity of current consumed. Therefore the Commission held that a rate increase within practicable limits offers no solution of the difficulty.

NEW MINIMUM RATES FOR SERVICE EXTENSIONS.

Puget Sound Traction, Light & Power Co. Files New Minimum Monthly Charges.

Proposing a plan by which the cost of extension of electric light service to residences not located on established circuits of the company will largely be borne by the consumer for whose benefit the extension is made, the Puget Sound Traction, Light & Power Co., of Seattle, has filed a schedule of rates with the State Public Service Commission of Washington, which under the 30-day provision of the law are not changed as to the kilowatt-hour consumption, but the new schedule affects the minimum charged the consumer who requires an extension to secure service.

For one customer, where one pole and service extension is required, a minimum rate of $2 a month is to be charged. For one customer, two poles and extension, the rate is $3 minimum. For two customers, one pole and extension, a minimum of $2 each is charged and for two customers, where two poles are required the minimum rate is $2 each per month. All contracts under the new tariff are for a period of three years. Under the present schedule the minimum charge is $1 a month.

The new tariff is filed on behalf of the subsidiaries of the Puget Sound Traction, Light & Power Co. and affects Seattle and King county, Tacoma and Pierce county, Everett and Snohomish county, Bellingham and Whatcom and Skagit counties.

BIG GAINS IN BUSINESS AT MINNEAPOLIS.

More Electrical Appliances Sold in First Six Months of This Year Than All of Last Year.

During the first six months of 1919 the Sales Department of the Minneapolis General Electric Co. disposed of more electrical appliances than during the entire 12 months of 1918. A comparison of these figures and other new business secured for the first six months of 1919 with the corresponding period of 1918 is as follows:

	1918	1919	Increase
Already built houses wired	1847	2067	12%
Appliances sold (number)	1701	1964	15%
Appliances sold (value)	$15,656.32	$47,861.03	205%
Ranges sold (number)	62	208	235%

During the week ended July 4, the sales department took contracts for 345 new electric light and power customers with 191 kw. of light and 607 hp. in motors. The net gain in business connected for the week was 165 customers with 179 kw. of lighting and 162 hp. in motors. The electric energy output for the week was 36.6% greater than for the corresponding week of last year.

Operating Practice

Instantaneous Detection of Generator Fire—Knife-Switch Inspection—Advantages of Parallel Feeders—Line Costs

PROPOSED METHOD OF DETECTING FIRES IN TURBOGENERATORS.

Outgoing Air to Be Used as Tell-Tale of Conflagration in Big Machines.

Turbogenerators may have caught fire and be burning for some considerable period of time, comparatively speaking, before the fact is discovered by the operating force. And by that time affairs have well advanced and damage that leads to still worse damage has usually occurred.

One way of enabling the internal conditions of turbogenerators to be watched is to enable the condition of the outgoing air to be made visible; another is to have some sort of indicator installed so as to indicate the passage of smoke or flame with the outgoing air. In some instances glass windows, of leaded glass, have been used, and in this way enable the operating force to see into the outgoing air passage. However, such a practice is unreliable, since inspection is necessary to make the practice reliable; and at best an inspection may not tell the whole story.

In one recent instance of a company operating a large number of turbogenerators, several of which have caught fire and destroyed themselves during the last three or four years, the outgoing air is passed to the boiler room, where its heat is used by the fuel beds of the furnaces, thereby increasing the efficiency somewhat. To prevent an internal turbogenerator fire existing unnoticed in this installation it has been proposed to install an indicator by which any abnormal condition of the outgoing air can be readily detected. This indicator will consist of a metallic pipe, of a cross-section small compared to the total cross-section of the air duct, for example about 1 ft. diameter, which would be located at the exhaust of the generator in the turbine room. In this way any sparks, flame or smoke going through the air duct would come to the attention of the operating force in the operating gallery or on the turbine-room floor.

PERIODIC INSPECTION OF KNIFE SWITCHES ADVOCATED.

Reduction of Energy Loss and Better Regulation at Heavy Amperage.

By B. Hamilton.

In stations transmitting heavy amperage as, for example, substations supplying Edison three-wire systems, there are many heavy-ampere knife switches, most of which are loaded a considerable portion of the 24 hours. Also in many large industrial establishments using either alternating or direct current, the former at 220 or 440 volts, the current values may attain considerable magnitude.

Heating occurs at the knife switches, sometimes because the current exceeds the switch rating and more often because the surface of contact between the blade and the clips is not the best. With alternating current there is an added loss due to eddy currents.

The heating at switches, when excessive, represents a waste of energy; it causes a voltage drop that tends to interfere with voltage regulation and often times causes injury to the switch. The writer has found switches where the blade and the clips had become so heated as to be almost welded together so that the switch could not be opened readily, nor when once opened closed again.

The remedy is to make periodic inspection of switches carrying heavy currents. This inspection may merely consist of feeling the switch by hand to determine temperature or may consist of taking measurements of voltage drop across the switch and between blades and clips. Heating due to poor contact can be reduced by cleaning the surfaces of contact. Wiping these surfaces with a thin layer of vaseline also reduces the drop, although but only a small quantity of the lubricant should be employed. Some of the larger companies handling heavy currents over many switches have determined limits of heating and voltage drop above which they do not allow their switches to go. The practice is a worthy one.

PARALLEL OPERATION OF FEEDERS REDUCES CABLE BREAKDOWNS.

Reduction of Investment Also Additional Benefit Obtainable from Parallel Feeders.

The savings which can be effected by a parallel operation of feeders depends in a large degree upon the design of the transmission system and the ratio of the capacity of the line to the capacity of the individual synchronous converters or transformers, which are supplied by this feeder. In one system supplying converters varying from 500 to 4000 kw. in size together with step-down transformers in substations of 1500 and 3000 kw. capacity and also industrial substations on the premises of customers ranging from about 500 to 4000 kw. in capacity, it was estimated that if the feeders could be operated in parallel then a saving of 20% could be made in the amount of investment. This fact was brought out at the recent A. I. E. E. convention. As the installation in question had a book value of about $5,000,000, there was a possible saving estimated at $1,000,000. This company has been operating feeders in multiple for about two years. During this period they have realized nearly 40% of the possible saving in the investment in feeders, and this has been secured by an actual reduction in the number of feeders, notwithstanding a considerable increase in the maximum load.

The same company also reports in the four years preceding the installation of the relays permitting parallel operation of feeders that they averaged 27 burnouts per year which could not be definitely ascribed to external causes, while in the two years since the feeders have been operated in parallel, the corresponding figure was 16 burnouts. This would indicate a reduction of 40% in the burnouts of cables due to operation of the feeders in multiple, although the cables were actually more heavily loaded. While the time is rather too short to accept these figures as final and conclusive, it apparently indicates that the operation of feeders in parallel reduces the number of troubles due to internal causes.

ITEMIZED COST OF 33,000-VOLT TRANSMISSION LINE IN CENTRAL ILLINOIS.

Line Built During War to Supply Coal Mine with Central-Station Service.

The itemized cost of constructing this transmission line, together with a list of material, is appended:

Poles.

Cost per mile	$ 3,181.14

POWER TRANSMISSION AT 220,000 VOLTS.

Much interest has been aroused in the paper by A. E. Silver before the recent Lake Placid convention of the A. I. E. E., in which he discussed the possibilities, theoretical and practical, of power transmission at 220,000. An abstract of this paper appeared in Electrical Review July 12. The following gives another aspect of this subject.

Certain features of the problem are high reactance of generators and transformers, ample insulation of transformers and an efficient oil circulation system, high mechanical strength of oil switches, avoidance of low-voltage buses and low-voltage paralleling, and an effective and dependable system of relay sectionalizing. All line switching, automatic or manual, should be done on the high-voltage side of transformers. The amounts of power involved, particularly under abnormal conditions, are so tremendous that the current values obtaining at lower voltages impose switch duties and heavy stresses generally which could be handled only with great difficulty and at an expense materially higher than would be required at 220 kv., when the currents involved are relatively small. No equipment of any character is contemplated for protection against over-voltages.

Contracting-Construction

How to Make Old House Wiring Pay—New York Contractors Hold Outing—Evansville Electrical Firm Reorganized

SUCCESSFUL METHODS OF CONDUCTING OLD HOUSE-WIRING BUSINESS.

How Dempsey & Meade, Chicago, Makes This Class of Work Pay Real Profits.

Among the electrical contracting firms in Chicago that specialize in the wiring of already built buildings, one of the most successful is Dempsey & Meade, located at 3153 W. Madison street. Organized in 1908, this firm through the persistent efforts of its owners and the up-to-date business policies they adopted, has grown rapidly until at the present time it occupies a prominent place in the local contracting fraternity and enjoys an enviable reputation throughout the city.

Schedule..........

Dear Sir:-

We wish to respectfully submit you an estimate of..........
for wiring your .... story.......... residence for electric light at the above address, and..........for furnishing and installing fixtures for same as hereinafter noted:

The work to be done under this contract will consist of wiring ....outlets for..........lights;..........outlets for single and double pole switches; and..........outlets for 3 way switches, as follows: Ceiling height..........ft..........in..........meters.

LIGHT OUTLETS Telephone No..........

Location Ceiling Wall Baseboard Lights Switches	Fixtures
Porch	Ceiling holder, bracket or chain pendant
Vestibule	Ceiling holder, bracket or chain pendant
Hall	Chain pendant or bracket
Hall	Chain pendant or bracket
Stairs	Chain pendant or bracket
Parlor	Semi-direct bowl or shower
2nd Parlor	Semi-direct bowl or shower
Dining room	Shower or bowl with ( ) drop shades to match
Library	Shower, bowl, or chain pendant
Sitting room	Shower, bowl, or chain pendant
Pantry	Drop cord and guard
Kitchen	1-1x1 pendant
Basement	Drop cord
Laundry	Drop cord
Upper hall	Chain pendant or bracket
Bedroom	Chain pendant or bracket
Bedroom	Chain pendant or bracket
Bath	Chain pendant or bracket
Attic	Drop cord

Fig. 1—Contract Form That Provides for Description of Work to Be Done.

One factor contributing to the success of this concern is that it has specialized in this particular field of electrical work, educating its workmen in this line and building up its organization to best meet its special requirements. Just now, this organization has been developed along this line to such an extent that it has not as yet been deemed advisable to branch out into new building work although recently the opportunities for such work have been very good.

Another is its policy with relation to its customers, competitors and the electrical industry as a whole. Early in its existence the firm began a policy of good service in addition to a high quality of work and its acitvity in this respect is largely responsible for its present position. In order to avoid any misunderstanding with its customers and to correct any difficulties that may arise as soon as possible, arrangements have been made so that the customer must sign forms stating that the work already done is entirely satisfactory before any job can proceed or is considered completed. It has also co-operated in many ways with the other local branches of the industry and its members are very active in local electrical organizations, Mr. Meade being president of the Commercial Electrical Contractors' Association.

A third and equally important factor is its policy to determine accurately and promptly the exact cost and profit on every job and not to take any work at a price which will not show a suitable profit. Its attitude in this matter is ably expressed by Mr. Meade, who says "If you want to gamble on a building, buy it."

To accomplish this every job is costed immediately upon its completion which shows whether the method of estimating is correct or not and also the performance of the workmen on that job. The firm endeavors to employ only the best and most efficient workmen and as a reward endeavors in turn to keep them employed as continuously as possible.

Remarks..........

Fig. 2—Material Sheet Used by Dempsey & Meade, Chicago, for Keeping a Record of All Materials Used.

The methods and forms which it has developed for its use are very simple and designed to eliminate confusion or duplication as much as possible. The form shown in Fig. 1 is the first page of its contract. On this form space is provided for the price of the job, a brief description of the building and the total number of outlets, lights, switches, meters, etc. Below provisions are made for the listing of each outlet and switch, together with its location in the room. On the right is listed a description of the fixtures ordinarily used in such rooms, the ones not selected being scratched out by the estimator. Space is also provided to insert the number of sockets desired in the fixture. The second page of the contract provides for the method of payment, and the signatures.

When the contract is received at the office it is given to the foreman who goes to the job and orders out the material on the form shown in Fig. 2. On this form practically every class of material used in this work is listed with four columns opposite marked Materials Out, Materials In, Materials Used and Materials Cost. The first of these columns is used by the foreman in ordering the material for the job. The second and third are filled in by the workman after he has completed the job and records the amount of materials left over to be picked up and the amount used which is obtained by subtracting the quantity shown in the second from that in the first column. The materials used are costed at the office and recorded in the last column.

The labor charges are recorded on the form shown in Fig. 3. On this, spaces are provided for the journeymen's name, the total number of hours of labor on the job. Below this is a space for listing the number of outlets or fixtures, their description and location as taken from the contract form. A separate labor slip is provided for the different wiring operations. Below the description of the installation space is provided for the customer's signature stating that the work as done is satisfactory.

The form shown in Fig. 4 is a small card used

for recording the time and materials used in small repair or additional jobs. As on the previous forms space is also provided here for the customer's signature.

A large percentage of the wiring jobs done by the firm is taken on a time-payment plan. The financing of this plan is done through the Commercial Electrical Contractors' Association by a local banking house. The method employed in the operation of this plan is for the customer to sign interest bearing notes, for which suitable forms have been devised, which are purchased from the contractor by the bank. At present the company itself is making the collections on these accounts.

In spite of the success that the company has achieved in this field of contracting, the members

are convinced that the real opportunity lies in the merchandising field and for this reason it has already started to build up an organization to carry on this work on an extensive scale. The possibilities of merchandising were quickly realized by this concern when it first took part in the co-operative sales campaign inaugurated in Chicago about two months ago. The results obtained thus far without any intensive sales effort being made have greatly exceeded all expectations. For this reason the company plans to double the size of its present quarters, hire salesmen and solicitors and to develop another organization to work in conjunction with its present one as quickly as possible.

NEW YORK CONTRACTORS HOLD ANNUAL OUTING.

The fifteenth annual outing of the Independent Electrical Contractors' Association of Greater New York was held at Grant City, on June 21. On this occasion the members and their guests participated in numerous athletic events which were closely contested and in addition several novelty and entertainment features were introduced, including running the prohibition law. About 400 men representing the various branches of the electrical industry were present and the consensus of opinion seemed to be that this was the finest affair of its kind ever held by the association.

EVANSVILLE ELECTRICAL CONCERN REORGANIZED.

The A. L. Swanson Co. of Evansville, Ind., one of the largest concerns in that section engaged in electrical construction, repair and maintenance, and jobbing work, has recently reorganized and in the future will be known as the Swanson Electric & Manufacturing Co. The purpose of the reorganization was to increase the capital of the company in order to extend its jobbing and manufacturing facilities. A. L. Swanson, chairman of the Indiana State Association of Electrical Contractors and Dealers, will remain as president of the new concern.

Contractor-Dealer

New Merchandising Companies Formed—Successful Window Displays—Methods of Securing Children's Friendship

COMPANY FORMED TO RETAIL ELECTRICAL PRODUCTS IN CHICAGO.

Home Appliances, Inc., Plans to Open Several Attractive Retail Electrical Stores.

The Home Appliances, Inc., has recently been organized in Chicago for the purpose of merchandising electrical household appliances on an extensive scale. The company plans to open three attractive stores in this connection, one on the north side of the city, one on the west side, and one on the south side. The north side store is to be located at 3301 Lawrence avenue and is expected to be ready for business shortly. The one on the south side will be located at 6530 South Halsted street. Both of these locations are in the heart of thriving business districts where the need of attractive electrical stores is evident. The location of the third store has not as yet been decided upon but it is expected that a prominent store in one of the numerous business communities of that section will be arranged for shortly.

The new firm will handle the complete line of Western Electric Co. products for home use and will also carry a large stock of other merchandise, such as ornamental floor and table lamps. The stores will be made as attractive as possible and conducted along the most approved modern merchandising methods.

George Ledell, formerly of the Electric Shop of the Commonwealth Edison Co., has been appointed general manager of the new company. Mr. Ledell has had considerable experience in the retailing of electrical merchandise, which insures the success of the new enterprise to a large extent.

NEW ELECTRICAL FIRM ORGANIZED IN ROCHESTER, MINN.

Rochester Electric Co. Plans to Carry on an Extensive Merchandising and Construction Business.

A new company to be known as the Rochester Electric Co. has recently been incorporated at Rochester, Minn., for the purpose of conducting an electrical contracting and merchandising business in that section. The incorporators are E. M. Raety, William F. Hines and Henry Blink, all of Rochester, and who have been intimately associated with the electrical industry for many years and have had considerable experience in their particular lines.

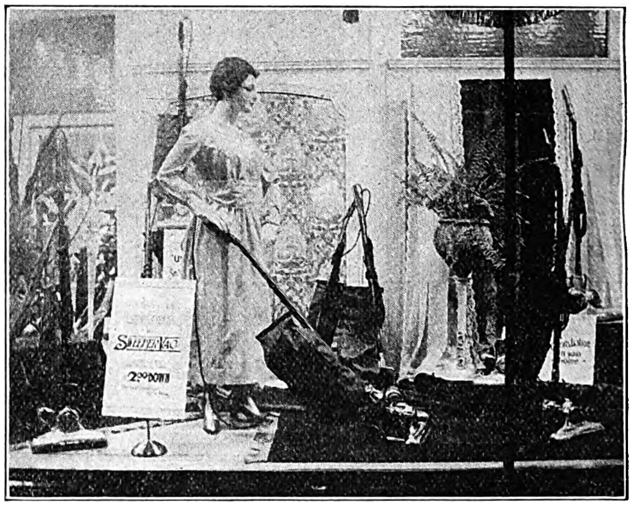
The new firm has already secured a considerable amount of construction work, one of its most important jobs being the men's dormitory at the Rochester State Hospital. In the merchandising field it is the present intention to specialize on Hughes ranges, Packard lamps, Columbia dry cells, Emerson fans, Simplex ironers, Thor washers and the Hotpoint line, and in the thriving city of Rochester with its many hospitals and hotels the company anticipates a good patronage.

ATTRACTIVE WINDOW DISPLAYS THAT PROVED SUCCESSFUL.

Recent Advertisements and Window Decorations That Have Produced Results.

By W. B. Stoddard.

Comparisons may be odious but when they point such an effective moral as the comparative displays of the Bureau of Power, Los Angeles, Cal., they are decidedly to be commended especially from a publicity standpoint. In urging the wiring of the house for electricity, and playing up the advantages of electrical equipment, this company recently arranged two windows. The first showed the old fashioned household conveniences,—the candle, the kerosene lamp, and the open flame gas jet; the frazzled broom; the rusty flatiron; the coffee pot; and the gas toaster that always burned the toast. A card on the floor observed: "The Old Way." The second window showed the Mazda light; in an art metal stand lamp; the capable vacuum cleaner; the electric iron; the aluminum percolator; and the electric toaster that toasts so evenly and crisply. A card at one side observed: "Be Up-to-Date—Wire Your Home Now." On the wall was a big white disc with the figure "5 Cents." Beneath this was another card advising what this small amount of money can accomplish in comfort and convenience when used to purchase electricity.



Attractive Vacuum Cleaner Display by Portland, Ore., Contractor-Dealer.

The Brooklyn Edison Co., Brooklyn, N. Y., gave a practical demonstration of the ease and comfort with which the family ironing is done by the use of electricity. A little girl of about 12 was shown manipulating an electric iron on a piece of soft white goods, the motive power being a fancy electric lamp which stood on the end of the ironing board. Piled up in front were boxes containing these electric irons, as well as several of the irons unboxed, so that they could be seen to better advantage. Cards set up at different points in the window gave definite advice as to the advantage of electricity compared to the old fashioned iron:

> No steps to and from the hot stove—
> all the heat is in the iron.
> One iron does all the work—
> no tiresome changing of handles.
> Average family ironing done at a cost of
> less than 15 ct. a week.
> Prepare in advance for the hot summer days. The electric iron shortens the labor—saves the strength.

The solution of the wash day problem that is puzzling the housewives in every part of the land is suggested by the Wilmington Traction Co., Wilmington, Del., in their decidedly effective display window. On the glass was pasted a clipping taken from one of the local papers:

CITY SHORT OF WASHERWOMEN

IN CONSEQUENCE, MANY HOME TRAGEDIES ARE BROUGHT TO LIGHT—WON'T COME BACK TO THE TUBS.

A washerwoman in Wilmington is as scarce as hen's teeth. The lack of this Pride of the Tubs is causing many tragi-comedies in domestic life. The 5-cent stores are doing a tremendous trade in paper table cloths and napkins, as many women have adopted these don't-have-to-be-washed substitutes for table linen until Dinah comes back to the washboard. What is puzzling the housewives is that, although munition work has stopped, the washboard ladies show no signs of returning to their tubs.

In the middle of the display was shown an electric washing machine in operation, churning the suds at a great rate, and red ribbons ran from it to cards set in racks which read,—"Let the Electric Washing Machine be your dependable washwoman—always on hand and always cheerful"; "An Electric Washing Machine will save you all the troubles and worries of wash day, and will always be on hand when wanted"; "An Electric Washing Machine doesn't require three meals per day, and doesn't ask for car fare." The inference was so plain that he who ran might read, that the way to offset the shortage of laundresses was to buy an electric washing machine and do the work one's self in half the time.

The handy vacuum cleaner was attractively shown by Olds, Wortman & King, Portland, Ore., who showed a young woman in blue morning dress operating with ease one of the latest models. The window was fitted up to represent a drawing room with an Oriental rug, curtains of maroon, with over-draperies of lace, and a wicker flower stand holding a fern. A card down in front said: "Make play of your work by using a Vacuum Cleaner," and another suggested that the observer ask for a demonstration of the work of the vacuum cleaner in her own home.

During the summer mother is planning the clothes of the family for fall and winter, and a campaign for electric sewing machines should be gotten under way without delay. A decidedly successful one is being conducted by Barker Bros., Los Angeles, Calif. In order to arouse interest from the beginning they placed a modest advertisement in the paper:

HOW MANY TIMES CAN YOU WRITE OUR NAME ON A CARD?

A series of prizes will be given to the persons writing it the greatest number of times in a legible manner, without writing it over or across other letters. Come in and ask us about it.

This announcement of course piqued the curiosity and scores came to the store to learn about the offer. Each enquirer was handed a card with the name of the firm printed at the top, the remainder of the space being left free for the contestant to exercise his skill. On the opposite side was printed: "Write the name of three electrical household appliances which you do not possess." The rules of the contest were simple: All writing must be done with ink; all words must be legible; all cards must bear the name and address of the writer, together with those of three electric household conveniences. The addresses were tabulated, and the writers circularized with pamphlets describing the advantages of the electric articles mentioned on their cards. The prizes offered were electric household conveniences, displayed in the window prior to the decision of the judges.

This contest was followed by a concise, pointed newspaper advertisement, adorned with cuts of vacuum cleaner, sewing machine motor, and electric washing machine, all operated by young matrons in neat morning dresses. These were forceful; worded as follows:

LET MODERN ELECTRIC EQUIPMENT MAKE MORE SPARE HOURS FOR YOU—COME TO BARKERS

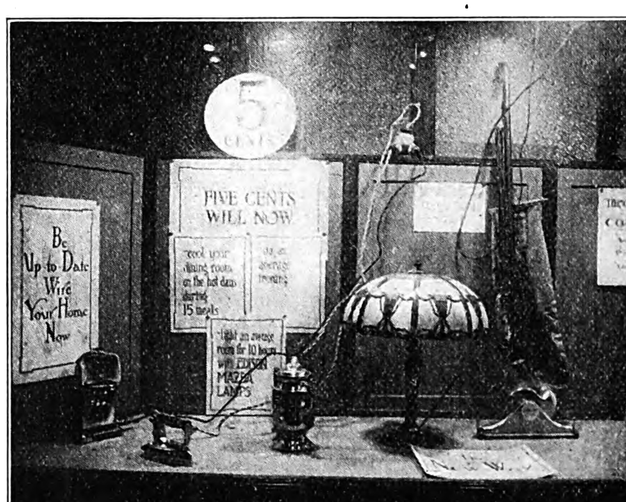
Let us show you how quickly, easily and pleasantly you can do all your housework with better equipment—electrical, of course.

THESE ARE THE IMPORTANT TIME SAVING NECESSITIES

Electric Sewing Machine Motors Electric Vacuum Cleaners
Electric Washing Machines

The window was fitted up as a sewing room, in

"The Old Way" as Displayed by a Los Angeles Company.



And "The New Way" Shown in the Next Window.

which sat a woman making a child's dress, using an electric motor to operate the machine. A card suggested: "One can operate this sewing machine all afternoon without fatigue, as it requires head power, instead of foot power, to run it." At certain hours of the day, when traffic was heaviest, a neat maid could be seen going over the room with a vacuum cleaner; while a large card in the window advised: "Be sure to visit our model electric laundry on the second floor." This laundry was fitted up with electric washing machine, ironer, and well arranged lighting system. There was also an electric fan on a stand, and a card said: "There will be no Blue Mondays when one has a model electric laundry in which to pleasantly and swiftly do the weekly washing."

GETTING IN GOOD WITH THE CHILDREN.

Methods Employed by Merchants to Secure Children's Friendship and Its Value to the Store.

By Ernest A. Dench.

Children are more susceptible to bribery than anybody else, crooks excepted. Of course, children cannot be put in the same category as crooks, for the good and simple reason that youngsters are totally innocent of any wrong doing. If it is bribery, it is a commendable and totally inoffensive form of bribery, for it makes the children happy, eases things for their parents and attracts trade for the merchant.

Following this idea, a merchant in Tupper Lake, N. Y., secured an excellent assortment of cunning, happy dolls with cheerful faces. The customer spending $1 in the store during the three weeks set aside for the campaign received one neatly dressed doll, 11 to 14 in. high. If the purchase amounted to $5, the little girl who accompanied her mother was given a medium size, neatly dressed doll, 17 in. high. But if the little girl succeeded in inducing her mother to spend $10, she was rewarded with one large size, finely dressed doll, 20 in. high.

Charles Mayer & Co., Indianapolis, Ind., made a certain Friday a "Red Letter Day" for little girls. On this particular morning every girl in Indianapolis who possessed a doll was invited to bring her doll to the store. There was no distinction and it was pointed out that it did not matter whether the doll's clothes were torn or faded, whether the face was chipped or dirty, or the doll big or little, pretty or homely, light or dark, so long as it resembled a doll.

The only rule every girl had to observe was to pin a piece of paper to the doll with her name and address plainly stated. On Saturday the dolls were placed in the window and the overflow placed on exhibition in a prominent place inside the store. Every girl was invited to see the exhibit. On the following Monday a group picture was taken of the dolls. On Tuesday morning each girl calling at the store for the return of her doll was presented with a copy of the doll window picture.

As can be imagined, the stunt got the store talked about in thousands of Indianapolis homes solely by the mouth-to-mouth publicity of the children. It got every girl's goodwill, and aside from getting the parents interested in the store it must be remembered that the stunt will do the store good in years to come, when the little girls are grown up and have little girls of their own.

Evans, Indianapolis, Ind., recently ran a series of "Flags of Our Allies" in the local newspapers. Half of each advertisement was devoted to a reproduction of a flag and a brief description of it and the other half of the ad was devoted to the store.

In the public schools at the present time most of the history and geography lessons are being devoted to our gallant allies in the great war. This has resulted in every teacher availing herself of every means to inform her pupils more about these countries. She grasps every opportunity to get home the facts as a cat pounces upon a mouse, so the electrical dealer who assists her in this connection is sure of her hearty co-operation. Children hate to have knowledge crammed into their systems, but it is surprising how much knowledge they will pick up if there is an inducement connected with it. This Evans realized in inviting the school children to cut out the advertisements, which appeared every Tuesday and Saturday. The children were then told to color the flags with crayon or paint and they would soon have a full collection of the flags of our Allies. This stunt might be improved upon by offering prizes for the best colored flags.

The Live and Let Live Store, Chattanooga, Tenn., knowing how children worship their war idols, offered a photograph, size 15 by 18 in., of President Wilson or General Pershing with every purchase amounting to $2.

It will always pay the electrical dealer to take the children into consideration for, in addition to affording a valuable medium of gaining immediate publicity, it assures the future growth of the store. For the child will be grown up some day and the favorable opinion thus formed of a merchant while the child is in the impressive age, will remain long after it is old enough to utilize its own judgment of things.

PREPARING FOR THE AUGUST CLEARANCE SALE.

August has been generally accepted by the electrical retail trade as the "clearance sale" month, when the wideawake electrical dealer cleans out his slow-moving stock. Several valuable suggestions for the preparation and conduct of such a sale were given in an article in the Monthly Sales Service of the Society for Electrical Development recently.

Before starting a sale of this kind the merchant should carefully analyze his stock to determine what goods were moving too slowly and must therefore be sold, and also the reason in order that he may avoid such difficulties in the future. After selecting the goods to be sold at reduced sale prices he should choose a suitable name for his sale. "Clearance Sale" alone has some advantages but its value may be considerably increased by the addition of some other word, such as "Electrical" or "Combination," while a distinctive name, such as "Red Letter Sale" or others commonly employed by department stores is even better. This name should be featured in all the dealer's advertising during the month and special pains should be taken to keep up interest in the sale by always featuring some especially attractive article.

In pricing the goods it should be remembered that they have no value as long as they remain on the shelves and that their sales possibilities grow less every day. For this reason the prices should be made low enough to insure their sale. But the selling price should never be reduced without giving some reason for otherwise the customers will think that the prices were too high in the first place.

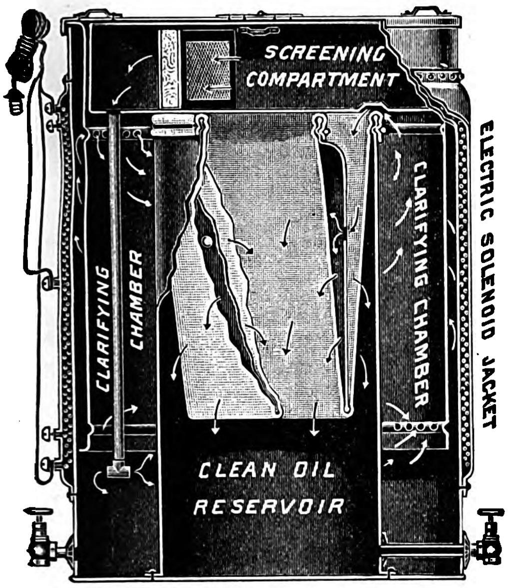
New Appliances

Oil Filter for Screening, Clarifying and Filtering Oil—Triple Die Stock for Facilitating Pipe and Conduit Work

The Electrically Heated Simplex Oil Filter.

The bearings of electrical and other rotating, reciprocating and oscillating machinery must be thoroughly lubricated to minimize friction. Oil used for this lubrication should be frequently filtered and cleaned of sediment or other impurities if it is to be used over and over again, as is now customary for economy. Removal of the particles of metal, dirt, etc., maintains the oil at its best lubricating quality and prevents cutting of the bearings and thus reduces friction.

Oil is also extensively used in electrical apparatus, such as transformers, oil switches and circuit-breakers, etc., for its insulating and heat-dissipating properties. Such oil should also be frequently filtered and purified, if it is to retain its dielectric quality at a reasonably high value.



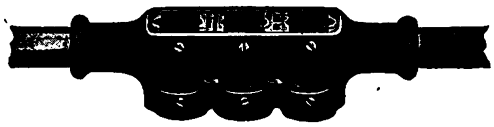
Electrically Heated "Famous" Oil Filter, Which Screens, Clarifies and Filters Oil for Reuse.

In the accompanying illustration is shown an oil filter designed especially for treating oil used for lubrication. It is also useful, however, for filtering oil for electrical purposes. It is known as the electrically heated simplex type of the "Famous" oil filter manufactured by the Famous Filter Co., 116 Pine street, St. Louis, Mo.

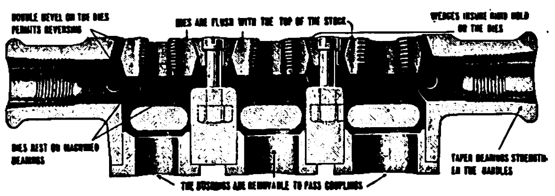
Operation of this filter is very simple. The dirty oil is poured into the removable screening compartment and percolates through the strainer wall and screening material. This thoroughly screened oil then descends through the feed pipe and spreading tee and enters into the clarifying chamber, near the bottom thereof at the left-hand side. As this chamber is always full of the oil which is undergoing the clarifying process, filtration takes place only after the oil level reaches the top of the clean oil reservoir, thus every drop of the oil must take its course and gradually travel upward and across to the other side during the clarifying process, so that all heavier particles of impurities and entrained water are separated from the oil and precipitated upon this chamber, whence they are withdrawn, occasionally, through the water and dirt drain valve at lower left side.

From the upper right-hand side of the clarifying chamber the oil passes into the filtering receptacle in the middle and filters through this dense filtering cloth, finally flowing into the clean oil reservoir, whence it is delivered as a high-grade oil at the clean oil valve shown in the lower right corner. By this process of first screening and clarifying the oil the cloth has to remove merely the few lighter impurities as only the cleanest oil filters through the exceedingly large area of washable high-grade filtering cloth surface presented by the patent self-contained and easily removable, double filtering-wall tension-truss receptacle.

It has been found that clarification or precipitation of particles in the oil is considerably facilitated by having it moderately warm as this increases its fluidity. For this purpose in the type illustrated there is provided an electric heating jacket that can be operated on either 125 or 250 volts, taking only 60 watts per gallon of oil reclaimed in either case. For 125 volts the two valves of this element are connected in parallel and for 250 volts they are connected in series. Since this heating coil is in the form of a solenoid, it possesses considerable magnetic properties causing particles of iron to be withdrawn from the oil more readily and completely than by slow gravity precipitation alone.



Trio Die Stock Complete.



Sectional View of Trio Die Stock, Showing Details of Construction.

Trio Die Stocks for Conduit Work.

Among the pipe tools which have been gaining in prominence until they have finally assumed the position as leaders in their line are the Trio die stocks, manufactured by the Greenfield Tap & Die Corp., Greenfield, Mass. This rise to prominence is due in a great measure to their excellent work during the war, when results were imperative.

The Trio die stock, as its name implies, contains dies and bushings for threading three sizes of pipe, all mounted in a single stock. This tool is therefore unique in the conduit and pipe-threading field. It is always ready to thread any one of its three sizes without any change or adjustment of any kind.

The next important feature of the Trio die stocks is that they are fitted with the well-known "Little Giant" pipe dies. These dies are made with a double bevel, a patented feature which permits the dies being reversed. This makes it possible to thread pipe projecting only a short distance up to a shoulder. By reversing the dies, the throat or chamfer is turned out. Adjustment of the dies is possible, as they are of the two-piece type and can be set to cut either exact or undersize by means of the set screws at each end of the die halves.

The simplicity of this tool, combined with its compactness, makes it extremely easy to use, and the fact that it accomplishes its work with a minimum of effort proves that its design is fundamentally correct. That this tool was designed with the user constantly in mind is evidenced by the choice of sizes included in the various models, there being one model with three sizes which are of extreme usefulness to the plumber and another with three sizes which are used continually by the electrician. The complete tool is surprisingly light in weight and can easily be carried in a kit bag by simply removing the handles.

The bushing guides used in this stock are so arranged that it is practically impossible to start anything but a straight, true thread and these guides, being removable, make possible the threading of nipples.

The manner in which the dies are held in place is worthy of notice as the well known three-angle principle is made use of. The dies bottom on a ground surface and are held absolutely rigid against the beveled side locating surface by wedges having bevels of the same angle as the side bevels on the die. Extremely accurate adjustments are possible as all the surfaces of the stock against which dies rest are machined.

Lately Approved Appliances

Underwriters' Laboratories, established and maintained by the National Board of Fire Underwriters (for service—not profit), have examined, tested and listed these electrical appliances in accordance with the Laboratories' Code for Construction and Test of Electrical Appliances. Copies of complete lists of standard applances may be obtained from local inspection departments or from offices of the Laboratories in the principal cities.

Armored Cable.—The Pratt-Chuck Co., Frankfort, N. Y.
Marking: Blue paper cord between wire and armor.
Listed June 30, 1919.

Attachment Plugs, Fuseless.—The Chelten Electric Co., 4859 Stenton avenue, Philadelphia, Pa.
Separable attachment plugs having composition bases and plain or brass-covered composition caps.
660 watts, 250 volts, Catalog No. 2500.
Listed June 5, 1919.

Autostarters. — The Electric Controller & Manufacturing Co., Cleveland, Ohio.
Automatically operated, oil-immersed switch and transformer mounted as unit in metal case, with no-voltage release coil and either with or without overload protective panel. In "off" position motor windings are disconnected from line. Separate switches are required to disconnect line wires.
Capacities, 150 hp. or less, 550 volts or less.
Listed May 21, 1919.

Cabinets and Cutout Boxes, Sheet-Metal. — Large-Dail Manufacturing Co., 114 North 13th street, Philadelphia, Pa.
Listed June 23, 1919.

Cabinets and Cutout Boxes, Sheet-Metal.—Massachusetts Electric Co., 18 Grafton street, Worcester, Mass.
Listed June 13, 1919.

Conduit Boxes.—Appleton Electric Co., 212-14 North Jefferson street, Chicago, Ill.
"Unilets." Pressed steel. Series FSP, FSW, Y, Z.
Note: These boxes, if not entirely exposed, must be securely fastened in place independently of support afforded by conduit. In all cases covers and attachments must be exposed and easily removable.
Listed June 14, 1919.

Conduit Boxes. — Cameron Overbagh & Co., 231 North Wells street, Chicago, Ill.
Listed June 24, 1919.

Conduit Boxes, Fittings for—Covers.—Cameron Overbagh & Co., 231 North Wells street, Chicago, Ill.
Catalog Nos. 312, 313, 400, 412, 413, 418.
Listed June 24, 1919.

Cutout Bases, Plug-Fuse.—Metropolitan Engineering Co., 1250 Atlantic avenue, Brooklyn, N. Y.
Combination service and meter-testing cutout bases, designed to facilitate meter testing.
M. E. Co., 0-30 amperes, 125 volts. Catalog No. 952 with wire conduit connectors, Catalog Nos. 9250-59 inclusive.
Listed June 3, 1919.

Cutout Bases, Plug-Fuse.—The Arrow Electric Co., Hartford, Conn.
"Arrow E." 0-30 amperes, 125 volts. Catalog Nos. 8020, 8042, 61935, 62135, 62165, 62199, 62569, 62587, 62965.
Listed July 1, 1919.

Electromechanical Gongs. — W. R. Ostrander & Co., 371 Broadway, New York, N. Y.
"Ostrander." Electromechanical gongs for fire-alarm or other signal circuits, 125 volts or less. Normal operating current 100 milliamperes.
Listed May 4, 1919.

Fixtures.—R. R. Cosby Electric & Machine Co., 1705 East Broad street, Richmond, Va.
Listed May 21, 1919.

Panelboards.—Massachusetts Electric Co., 18 Grafton street, Worcester, Mass.
Consisting of assembly of busbars, with or without cutout parts or with or without standard switches, mounted on insulating bases. Designed for use on low-potential circuits.
Listed June 13, 1919.

Receptacles for Attachment Plugs, and Plugs.—The Hart Manufacturing Co., Hartford, Conn.
"Diamond "H." 7½ amperes, 250 volts, 15 amperes, 125 volts, Catalog No. 1650.
Listed June 12, 1919.

Receptacle for Attachment Plugs, and Plugs.—V. V. Fittings Co., 1910 North 6th street, Philadelphia, Pa.
"V. V." 10 amperes, 250 volts, Catalog No. 43-H.
Listed March 31, 1919.

Sockets, Medium-Base.—Despard & Gordon Co., Chicago, Ill.
"Levolier." Metal Shell.
Pull, 660 watts, 250 volts, Catalog Nos. 1, 2, 3.
Listed June 19, 1919.

Switches, Knife. — Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.
"Westinghouse." Motor-starting knife switches, 30-60 amperes, 250 volts or 500 volts alternating current, 30 amperes, 600 volts, Type A. 30-60 amperes, 250 volts or 500 volts alternating current, and 100 amperes, 250 volts, Type C.
Listed April 25, 1919.

Switches, Push and Rotary Flush.—General Electric Co., Schenectady, N. Y.
Two-circuit, Catalog No. GE637.
Three-circuit, Catalog No. GE638.
Listed Jan. 30, 1919.

Transformers, Lighting.—Western Transformer Co., 329 East 18th street, Oakland, Cal.
"W. T. C." Air-cooled indoor transformers designed to supply current at following voltages to incandescent lamps for sign or house lighting. For use only when installed and wired in both primary and secondary circuits in accordance with Class C rules, National Electrical Code.
60 cycles, 1500 volt-amperes. Autotransformers 220-110 volts.
Listed April 5, 1919.

Wire Connectors. — Walger Connector Co., Bolton, Ont., Canada.
Wire connectors consisting of metal terminal plate with binding screws enclosed in molded insulating composition sleeve having threaded cap of same material. Straight Type S and three-way Types A and C. For use in joining wires of No. 12 B. & S. gauge or smaller, where such joints are accessible for inspection at all times. "Walger."
Listed April 26, 1919.

Wire, Rubber-Covered. — Astoria Wire Co., Astoria, N. Y.
Marking: One red and one yellow thread parallel to and between insulation and braid.
Listed July 2, 1919.

Wires-Miscellaneous.—Belden Manufacturing Co.. 23rd street and Western avenue, Chicago, Ill.
Pendent cord composed of two conductors, each of which is made up of stranded copper conductor of No. 18, 16 or 14 B. & S. gauge, insulated with cotton wrap, wall of rubber with asbestos covering. Conductors are twisted and provided with rubber reenforcement or filler to give round exterior and provided with outer braid of cotton.
Marking: Blue and yellow threads laid parallel with wire between rubber insulation and braid.
Listed May 23, 1919.

Wires, Slow-Burning. — Marlin-Rockwell Corp., Insulated Wire Division, New Haven, Conn.
Fixture wire consisting of stranded conductors, having felted asbestos insulation. This wire is furnished in single conductor with or without outer silk or glazed cotton braid and in twisted pair or twin wire with outer silk or glazed cotton braid. For use in fixtures within buildings, including fixtures for gas-filled incandescent lamps. "Rockbestos." Nos. 14, 16 and 18 B. & S. gauge.
Listed March 12, 1919.

Trade Activities

Tri-State Electrical Supplies Organized — New Branch Offices Opened by Manufacturers — Literature Distributed

Beaver Electric Co., Portland, Ore., has purchased the electric fixture business of the Kingery & Marrs Fixture Co., and is greatly enlarging that feature of its activities.

Burgess Battery Co., Madison, Wis., is establishing a branch at Winnipeg, to manufacture dry cells, flashlights and cases for its Canadian market, which has been growing rapidly. This new branch is being incorporated as the Burgess Batteries, Ltd., under Canadian laws, but it will be closely allied with the Madison organization through officers and engineering and sales departments. The manager is L. R. Baker of Winnipeg.

Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., has just recently issued quite an elaborate publication covering the process of electric arc welding and the necessary apparatus required for this process. This publication compares the different processes of welding, such as autogenous welding, forge welding, oxy-acetylene welding, thermit welding and shows the advantages of electric arc welding over these. Some of the advantages of electric arc welding shown are: Economy, ease and convenience of application, speed of operation, reliability of results, reclaiming defective material, safety, conservation of material, and less skilled labor required. The field for electric arc welding is unlimited and the process has made enormous strides during the last few years until now it is widely used throughout those branches of the metal industry in which work is done on iron or steel in rolled, cast or fabricated forms. New fields for its successful application are being discovered every day.

The Electric Auto-Lite Corp., Toledo, Ohio, has opened a new branch of its business at 221 Cherry street. This will be known as the Willys-Light division of the company and will market a home lighting plant for districts not supplied with current. At the sales room is a section fitted up in the fashion of a country home, which is fully electrified and modernized by the home power plant, and is as convenient and fully equipped as if it were located in a metropolitan community. This plant, which occupies 8 sq. ft. of floor space, will provide power to light a home, supply water pressure and operate such home electrical appliances as flatirons, percolators, washing machines and vacuum cleaners. It is estimated that 15,000,000 American homes are lighted by means other than electricity, and of these 6,000,000 are the homes of farmers. It is in districts not supplied with current that the corporation expects an especial demand. Distributing agencies for the plant will be located in some 20 cities.

Page Steel & Wire Co. has opened a branch office in Chicago, at 29 South LaSalle street. This office will handle all Armco iron products, including Armco welding rods, twisted pairs, plain and galvanized strand, bond wires, Armco iron fence and barbed wire and other brands of fence wire manufactured by the Page Steel & Wire Co. This company has opened another new branch office in the Book building, Detroit. Distribution in Canada is in the hands of Taylor & Arnold, Ltd., Montreal, Toronto, Winnipeg. Local distributers for Armco iron welding rods are located in all principal industrial centers. The sales of the Armco iron department are under the supervision of W. T. Kyle, sales manager, at 30 Church St., New York.

Vulcan Soot Cleaner Co., DuBois, Pa., has just published Bulletin 541, which illustrates and describes the Vulcan patented diagonal method for cleaning soot from the tubes of horizontal water-tube boilers. It embraces the following features: Thorough cleaning efficiency, long life, low maintenance cost, accessibility for inspection and repairs, ease of installation without interference with present boiler equipment and low first cost. Illustrations in two colors show typical designs as applied to horizontal water-tube boilers with vertical baffling. This bulletin also contains a discussion entitled "The Cost of Vulcan Cleaners and an Analysis of Their Value as Investments." This publication is free upon request.

Tri-State Electrical Supplies Co., Sioux Falls, S. D., is the name of a recently organized firm with an authorized capitalization of $250,000. Plans of the company contemplate making Sioux Falls the distributing point for electrical equipment of all kinds in the vast territory including South Dakota, Iowa and Minnesota. G. Denton is president and manager of the new organization. Associated with Mr. Denton as officers are N. C. Draper, formerly of the Northern States Power Co., as vice-president and electrical engineer; John C. Farley, secretary, and Miss M. E. Barrick, assistant secretary and treasurer. Mr. Denton will have executive charge of the business of the company, while Mr. Draper, who is an electrical engineer of long experience, will have charge of the sales department. It will handle construction material and manufactured electrical articles on a strictly wholesale basis. Electrical products, including motors, generators, telephone supplies, plant equipment and a wide range of electrical household appliances. A large modern warehouse will be erected, with trackage facilities for handling the enormous stocks that will be maintained.

The Cutler-Hammer Manufacturing Co., Milwaukee, Wis., has recently opened an office in Detroit, located at 905 Kresge building, to expedite the handling of orders and to give the company's customers in and about Detroit better engineering service. The Detroit office is, in reality, a branch of the Chicago office and bears the same relation to it as the Cincinnati office. H. S. Kinsley, who is in charge at Detroit, has taken with him from the Chicago office Messrs. C. W. Greenman and M. Dugliss, both of whom were recently mustered out of service. This trio will form the nucleus for the Detroit organization. Prior to going to Chicago, several years ago, Mr. Kinsley was connected with the engineering department at the Milwaukee plant.

The Trumbull Electric Manufacturing Co., Plainville, Conn., announces that the General Electric Co. has acquired a financial interest in the company, which, however, entails no change whatever in the present management, or personnel of the company. It will be the policy of the company to sell its material through the same distributers as in the past and on the same basis as to terms, price and service. The business of the Trumbull Electric Manufacturing Co., will be carried on in the future exactly as in the past in every particular. Work has been started on a new factory for the manufacturing of safety switches, which will increase the floor space of the plant about 33⅓%. This addition was made necessary by the rapidly growing demand for Trumbull safety switches, and the entire new building will be devoted to the production of this one line.

Marron Manufacturing Co., Rock Island, Ill., has brought suit for injunction against the Phelps Motor Co., of the same city, to restrain it from forfeiting a contract entered into between the two companies on Sept. 5, 1918, in which the selling of complete farm lighting lamps manufactured and assembled by the defendant was placed exclusively in the hands of the complainant. In entering into the contract the Marron company disposed of its previous rights in the manufacture of electrical apparatus used in connection with the complete lighting lamp, and turned this over to the Phelps company under the conditions cited. The complainant charges that the Phelps company has been violating the contract by selling and installing complete plants. A further feature of the contract was that the Marron company would take over the Phelps company at an agreed price in case the latter was unable to manufacture and deliver engines in certain quantities. This the Marron company is ready to do.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Wellesley Hills, Mass.—The Academy of Assumption, Oakland street, is planning for the construction of a boiler plant at the institution. With mechanical laundry plant to be installed, the work is estimated to cost about $50,000.

Wallingford, Conn. — Plans and specifications are being prepared for the installation of an additional 250-hp. boiler purchased nearly two years ago by the municipal electric light plant. Installation and piping, contract for which has not yet been awarded, will cost approximately $13,000. A. L. Pierce, engineer.

Providence, R. I.—A hydroelectric power plant to cost about $80,000, will be erected by the Nightingale-Morse Mills at their branch works at Putnam, Conn.

Brooklyn, N. Y.—Julius Kayser & Co., 45 East 17th street, New York, are making rapid progress on the construction of the large new power house at their plant on Classon street, Brooklyn, and it is expected that the work will be completed at an early date.

Brooklyn, N. Y.—Work has been practically completed by the Transit Development Co., 24 Broad street, New York, on the construction of the new addition to its power plant and electrical gallery on Kent avenue, near Wallabout Canal. Brooklyn, and it is expected that operation will be inaugurated at an early date.

Long Island City, N. Y.—In connection with the construction of the proposed four-story addition to the local plant of the Patterson Sargent Co., 8 Jay street, New York, estimated to cost about $300,000, large quantities of electrical equipment for operation will be required. Final contracts for the proposed structure have been awarded.

New York, N. Y.—Edwards & Co., Inc., manufacturer of electrical equipment, alarms, etc., with works at Exterior and 140th streets, has filed plans for alterations and extensions in its five-story factory to increase the present capacity. The work will cost about $40,000.

New York, N. Y.—American Precision Works, manufacturer of electrical, surgical and dental instruments, plans to remove its works to one of the suburbs of New York, where it will increase its manufacturing schedule and take up the production of instruments and apparatus for other industrial purposes. K. G. Frank is president.

New York, N. Y.—Loriam W. Young has leased the entire building at 214 East 40th street, and will establish a new works for the manufacture of electric lighting fixtures.

New York, N. Y.—In connection with its note issue of $6,000,000, to be used for the plant extension and improvements, the Sloss-Sheffield Steel & Iron Co., 56 Liberty street, is planning for the erection of a large central electric power plant. The new station will be used for service at its ore and coal mines, which are to be electrified.

Niagara Falls, N. Y.—Niagara Falls Gas & Electric Co. is planning for the erection of a new plant, to consist of seven buildings at Buffalo avenue and 22nd street, to cost about $200,000. A. H. Merritt is superintendent.

Persia, N. Y.—Application has been filed with the Public Service Commission by the Iroquois Utilities, Inc., for permission to make extensions and improvements in its electric plant and system in Persia and Leon, Cattaraugus county.

Poughkeepsie, N. Y. — Smith Brothers, North Hamilton street, are having revised plans prepared for the construction of the proposed industrial plant to be located at Michigan City, Ind. The works will comprise main manufacturing building, three-stories in height, with large power plant for general works operation, the project being estimated to cost $150,000.

Westfield, N. Y.—Armour & Co., Chicago, Ill., are making rapid progress on the construction of their two-story local plant and power house, about 200x1170 ft., and it is expected that operations will be inaugurated at an early date. The new plant when completed will cost about $300,000.

Boonton, N. J.—Boonton Electric Co. is arranging a new contract with the city officials for furnishing light and power service, including street lighting, for three years, commencing January 1, 1920, at present rates.

Dover, N. J.—New Jersey Power & Light Co. is making efforts to complete its new transmission line to Newton at the earliest date. Increased service is to be supplied at this point. The company has commenced the installation of new street lighting systems at Ledgewood, Succasunna and Kenvil. It is proposed to have the systems ready for operation early in October.

Newark, N. J. — Modern Electric Co., 518 South 19th street, has filed notice of organization to operate an electrical engineering and contracting business. Abraham Reichenstein, 347 South 12th street, heads the company.

Allentown, Pa.—To offset the construction of the proposed municipal electric power plant as now contemplated by the city, the Electric Light & Power Co. has tendered an offer to the city for a reduced schedule of charges. The company proposes a ten-year contract, which provides for the installation of 250-watt incandescent lamps to replace the present arc lamps. The new charge would be $38,886 as against the present schedule aggregating $49,300.

Carlisle, Pa. — An electric power plant, 30x94 ft., will be erected by C. H. Masland & Sons, Amber and Westmoreland streets, Philadelphia, in connection with their proposed carpet manufacturing plant on the former fair grounds at Carlisle. Bids for the building are now being asked.

Catasauqua, Pa.—The Town Council is having surveys made of the present street lighting system to devise plans for extensions and improvements. It is planned to install a modern system of lighting system, covering a total of about 43,275 cp. throughout the city. John A. Wise, President of the Eastern Pennsylvania Securities Co., is co-operating with the city in connection with the work.

Hershey, Pa. — An electric power plant, 13x140 ft., will be erected by the Hershey Chocolate Co. in connection with the proposed addition to its local plant to cost about $500,000.

Philadelphia, Pa.—The Hospital for Women, 4035 Parrish street, has filed plans for alterations and extensions in the power plant at the institution.

Pittsburgh, Pa. — Vetter Manufacturing Co., manufacturer of electrical specialties, has leased a seven-story brick building at 424-8 Second avenue, corner of Cherry Way, for new works.

Shamokin, Pa. — Susquehanna Collieries Co. is planning for extensions and improvements at its various plants to cost about $4,000,000. Considerable electrical and mechanical equipment will be installed for greater efficiency in operation. The company's properties are known as the Richards, Pennsylvania, Scott, Hickory Ridge, Hickory Swamp, Luke Fidler and Cameron Collieries. A new coal breaker will be constructed.

Shenandoah, Pa.—The City Council has had plans prepared for the erection of a new one-story electric pumping plant for municipal service to cost about $30,000.

Wilkes-Barre, Pa.—Acheson Bread Co., Main street, will build an addition to its boiler plant to cost about $10,000. Frank H. McCafferty is manager.

York Haven, Pa. — York Haven Water & Power Co., will soon commence the construction of a new transmission line to connect with the system of the Reading Power Co., at Annville, Lebanon County. Surveys for the line have been completed. The Reading company will extend its present line from Lebanon to Annville, to make the connection. The two power companies have also arranged for a tie in with other power companies operating at Philadelphia, Pottsville and Allentown. The York Haven company plans to connect with neighboring lines as well with its Middletown system.

Baltimore, Md.—Cambridge Iron & Metal Co., 2032 Aliceanna street, will install 50-hp. in motors.

Charleston, W. Va.—A new electric power plant, 40x60 ft., for works operation will be erected by the Virginia Rubber Co. in connection with its proposed new rubber manufacturing plant. The company was recently incorporated with a capital of $1,200,000. A. A. Lilly is president, and Houston G. Young, vice-president.

Wheeling, W. Va.—West Virginia Traction & Electric Co. has closed a contract with the Elkins Coal & Coke Co. for furnishing electric power for operation at its properties in Monongalia and Preston counties. The company plans for the complete electrification of its plants in every department of operation.

Lockhart, S. C.—Lockhart Power Co. is planning for the erection of a new hydroelectric power plant on Broad river. The structure will be 36x100 ft. reinforced concrete. Enslie Nicholson, president.

Orangeburg, S. C.—The City Council is planning for extensions in the local electric power plant to increase the present capacity. The work is estimated to cost about $70,000. E. Hawes is city engineer.

Hayesville, N. C.—Public Service Co. recently incorporated with a capital of $125,000, has acquired a local hydroelectric power plant to be used as its initial station. It is planned to build an addition to increase the present capacity, and to locate another hydroelectric plant on a water development on Shooting Creek. A six-mile transmission system will be constructed, with local distributing lines to furnish electric light and power throughout this vicinity. G. H. Haigler and W. J. Winchester head the company.

Pensacola, Fla.—A series of about 20 electrically operated centrifugal pumps will be installed by the Bruce Dry Dock Co., in connection with its proposed dry dock and ship repair plant. The plant is estimated to cost $450,000.

NORTH CENTRAL STATES.

Cleveland, Ohio—L. A. Sommer, 2934 East 55th street, Cleveland, will let contracts for a $75,000 power house. The building will be brick, steel and reinforced concrete construction, steam heating, plumbing, fireproof interior finish, motors, generators, pumps and boilers, and electric lighting.

New Concord, Ohio — $35,000 in bonds have been voted to purchase water and light plant.

DATES AHEAD.

National Council of Lighting Fixture Manufacturers. Midsummer convention, Cleveland, Ohio, Aug. 5 and 6. Secretary-treasurer, Charles H. Hofrichter, 8410 Lake avenue, Cleveland, Ohio.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 26-28. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Pennsylvania Electric Association. Annual convention, Bedford Springs, Pa., Sept. 3-6. Secretary, H. M. Stine, 211 Locust street, Harrisburg.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston Block, Seattle.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

American Electrochemical Society. Fall meeting, Chicago, Sept. 23-26. Headquarters, Congress Hotel. Secretary, Prof. Joseph W. Richards, Lehigh University, Bethlehem, Pa.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Hammond, Ind.—Northern Indiana Gas & Electric Co. has petitioned the Public Service Commission for permission to issue notes for $1,067,000 with which it is intended to make extensions and improvements. S. B. Walters, 571 Holmes street.

Indianapolis, Ind.—Nordyke & Marmon Co. has taken out a permit for the erection of an assembly room for motors, one-story, brick and steel construction, 802x100 ft., to cost $90,000. This work is in addition to the proposed factory additions that are to cost $350,000.

Indianapolis, Ind. — Drew Electric & Manufacturing Co., manufacturer of overhead fixtures for electric trolley wire, has purchased a two-acre site at Collamer avenue, and the Nickel Plate Railroad, East Cleveland, Ohio, where it will shortly begin the erection of a plant, machine shop and brass foundry to cost $50,000. James H. Drew is president.

Michigan City, Ind.—Architect W. P. Field, 763 Broad street, Newark, has prepared plans and will let contracts for a $150,000 industrial and power plant to be erected at Michigan City by Smith Bros., North Hamilton street, Poughkeepsie, N. Y. The building will be of brick and concrete construction, steam heating, plumbing, fireproof interior finish, boilers and pumps, electric lighting.

Portland, Ind. — Negotiations are under way with the directors of the Union Traction Co. of Indiana, relative to the purchase of the power plant at Detamore and the water rights of the Cartwright stone quarry. Portland is in need of a better equipped power plant and the Detamore plant will answer that purpose. The consideration is about $20,000.

Ashton, Ill.—At a meeting of the Ashton council the members took up the question of lighting the streets with electricity and a representative of the Illinois Northern Utilities Co. was present at the request of the council to give them the necessary information. The council finally decided to enter into contract with the utilities companies for a period of ten years for 50 lamps of the 100 cp.

Charleston, Ill. — Coles County Telephone & Telegraph Co. will place its cables underground in the business streets.

Chicago, Ill.—Holabird & Roche, 104 South Michigan avenue, have prepared plans and will let contracts for a $60,000 substation for the Commonwealth Edison Co., 72 W. Adams street, Chicago. The building will be brick construction, hot water heat, plumbing, fireproof interior finish, motors, generators and pumps.

Chicago, Ill. — Sears, Roebuck & Co. will erect a large warehouse at the northwest corner of Fillmore street and South Kostner avenue, adjacent to the B. & O. C. T. T. Railway. Plans are being prepared for the erection of a $400,000 paint factory. It will be a five-story structure to be used for the manufacture of paint and will be equipped with the most modern machinery.

Medora, Ill.—An election will be held on August 5 at Medora, to decide if $12,000 shall be issued to provide the village with an adequate lighting system. If the vote is to issue the bonds Medora will be connected with the Greenfield Service from Keokuk power.

Rockford, Ill.—Central Union Telephone Co. and the Rockford Home Telephone Co. have been consolidated by purchase of the latter by the Central Union Co.

Springfield, Ill.—Ira W. Fisk, consulting electrical engineer of New York, will assist in planning the additions and extensions to the electric plant which are to be made when the $400,000 bond issue is voted.

Urbana, Ill.—A street lighting system, ornamental in type, will be installed in the southwest part of the city, adjacent to the campus of the University of Illinois at a cost of $31,600. This is in addition to the installation of ornamental lights on West Green street at a cost of $6000.

Boyne Falls, Mich. — An election will be held to decide the question of issuing bonds to purchase electric pump for water system. Address village clerk.

Beloit, Wis. — City council has granted the street lighting committee permission to redraft plans for proposed ornamental lighting system in the business section. R. E. Wood, city clerk.

Fond du Lac, Wis.—Northern Basket Co. will erect a $75,000 factory, engine, boiler and power house, garage and warehouse.

Manitowoc, Wis.—The city will install electric lighting system on South 8th street. Arthur Zander, city clerk.

South Byron, Wis.—Plans are being prepared for the installation of an electric lighting system in South Byron. Electric energy for operating the system will be obtained from Kilbourne.

Fairmont, Minn. — The municipal electric plant, which has been operated for a number of years has discontinued the manufacture of electricity and is now purchasing its electric current from the Northern States Power Co., Sioux Falls, South Dakota division.

St. Paul, Minn.—Three new warehouses to cost $300,000, $400,000 and $350,000 respectively, a $200,000 paper box factory and a $500,000 candy factory are to be additions to St. Paul industrial activities some time during the ensuing year. Building permits during the first six months of 1919 total $4,318,000, almost equaling the total valuation of buildings actually erected in 1918.

Davenport, Iowa—Property owners on Perry street, between 2nd and 3rd streets, contemplate installation of ornamental lamps. Cost $2500. Hugo Moeller, city clerk.

Davenport, Iowa—H. C. Kahl plans erection of a $1,000,000 office building and theater, to contain theater seating 2500 persons, 234 office suites and 12 store suites. The building will be 150x147½ ft.

Eldridge, Iowa—At a special meeting held, councilmen voted an extension of electric power from Davenport. Approximate cost $6000. Fritz Weise, city clerk.

Mason City, Iowa—Western Electric Telephone Co. has inaugurated an extensive improvement program over the northwestern part of the state in the neighborhood of $200,000. A copper circuit is one of the improvements, to be installed by the company, and will be of the latest type. The company will also make other improvements. Further improvements to be made in Mason City includes the installation of private switchboards in the First National Bank and in the offices of the Northwestern States Portland Cement Co.

Ottumwa, Iowa—In a recent week the new business department of the Ottumwa Railway & Light Co., in conjunction with the local electric dealers, took orders for wiring 18 already built houses and disposed of 31 household appliances.

Chanute, Kans.—The council will secure an engineer to prepare estimates for a municipal light plant. Aug. 5 the question of issuing $75,000 will be submitted to vote. C. G. Wood, city clerk.

Harper, Kans.—Plans are in progress by W. B. Collins, Railway Exchange building, Kansas City, Mo., for waterworks improvements to cost $35,000. The work will include pumping equipment, engine and generator and pipelines.

Hugoton, Kans.—A new electric and water plant is being contemplated.

Manhattan, Kans.—Plans for the new electric light and power plant to be erected opposite the old plant have been drawn and the cost has been estimated at $500,000.

Winfield, Kans.—Bids will be advertised in the near future for improvements to the municipal light and power plant, including a 1000-kw. turbogenerator and auxiliaries at a cost of $45,000.

Lincoln, Neb.—The voters of the city of Lincoln will decide at a special election upon the purchase of the Lincoln Street Car Co. If the city takes over the lines it is the intention to create a new department with an expert on street car business at the head.

Towner, N. D.—At a regular meeting of the city council a committee was appointed to investigate the condition of the lighting service now existing and also to secure advice regarding the cost of installing a more modern lighting plant in connection with the city water system.

Gregory, S. D.—The question of issuing $122,000 municipal light bonds will be submitted to vote. Address city clerk.

Sioux Falls, S. D.—Building permits were issued to the Northern States Power Co. for brick and steel power plant on west side of Weber avenue. $7000.

SOUTH CENTRAL STATES

Louisville, Ky.—Fifty-one new electric light and power customers were secured by the commercial department of the Louisville Gas & Electric Co. during the week ending July 12 with 20 kw. of lighting load and 135 hp. in motors. Contracts were also taken for wiring 13 already built houses. The net connected load gain for the week was 33 customers with 7 kw. of lighting and 20 hp. in motors. Electric energy output for the week was 20.4% greater than for the corresponding week last year.

Mayking, Ky.—Mayking Coal Co. is considering the erection of an electric power plant at its properties for works operation.

Wolf Pit, Ky.—McKinney Steel Co. is planning for the construction of a new electric power plant at its works to cost about $60,000.

Centreville, Tenn.—An election was held to vote $12,000 bonds for the purpose of erecting a light plant for the town.

Ada, Okla.—Election will be held soon to vote $500,000 in bonds for waterworks extensions and storm sewers. Johnson & Benham, consulting engineers, Firestone building, Kansas City, Mo.

Broken Bow, Okla. — Election to vote $100,000 in bonds for waterworks and $30,000 for sanitary sewers, carried.

Enid, Okla.—Five hundred electric fans have been placed on the lines of the Enid Division of the Oklahoma Gas & Electric Co. so far this season. One dealer alone reports the sale of 200 electric fans. The Arctic Ice & Refrigerator Co. is installing 55 hp. additional motors which load is served by the Enid Division.

Hobart, Okla.—V. V. Long, consulting engineer, has been chosen to prepare plans and estimates for a new electric light and water plant. On submission of the plans, an election will be called to vote on the proposition.

Madill, Okla.—Johnson & Benham, Firestone building, Kansas City, Mo., are preparing plans for waterworks improvements to cost $60,000.

Tonkawa, Okla.—Election will be called soon to vote approximately $117,000 in bonds for waterworks and light extensions. Johnson & Benham, Kansas City, Mo., engineers.

Breckenridge, Tex.—J. E. Lewis of Dallas and associates have purchased the electric light and power plant here from Bert Paschall. New machinery will be installed and the capacity of the plant largely increased.

Eastland, Tex.—The electric light and power plant of the Eastland Light & Power Co. is to be enlarged to five times its present capacity in order to meet the growing demand for light and power, due to the remarkable growth of the town since oil was discovered here. The company plans to construct a system of electric power transmission lines through the oil field.

Hearne, Tex.—The capacity of the municipal electric light and water works plants here is to be enlarged by the installation of new machinery and equipment.

Houston, Tex.—Houston Light & Power Co. has arranged for a bond issue of $483,000 for proposed extensions and betterments. The company plans for the installation of a new 10,000-hp. turbogenerator, with auxiliary operating equipment at its plant, and for extensions in its transmission and distributing system. Samuel H. Bertron is general manager.

Kingsbury, Tex. — Arrangements are being made for the installation of a public lighting and water system.

Orange, Tex.—Orange Ice, Light & Water Co. has amended its charter, increasing its capital stock from $60,000 to $100,000. It will enlarge its electric light and power plant.

Waco, Tex.—Election will be held on Aug. 12 to vote on the proposition of a municipal gas and electric plant.

WESTERN STATES.

Ronan, Mont. — Flathead Valley Electric Co. will install several electric light and power plants in the Flathead Valley. Andrew Anderson, Plains, Mont., is president.

Bend, Ore.—Preliminary engineering work for the construction of an 1800 hp. plant on the Tumalo at the Columbia Southern ditch has been started by the Bend Water, Light & Power Co. The estimated cost is $125,000. Power development on the Tumalo was made necessary when plans for building a 5000-hp. plant at Lava Falls were canceled by tying up of all Deschutes water rights for irrigation.

Portland, Ore.—Extension of steam and electric mains planned and now under construction by the Northwestern Electric Co. will involve an expenditure of more than $100,000 according to G. C. Pierce, vice-president and general manager of the company.

Scofield, Ore. (P. O. Burton).—The Standard Box & Lumber Co. will rebuild its plant. The new plant is to be electrically operated.

Toledo, Ore.—The Fisher-Storey sawmill recently destroyed by fire is to be rebuilt on a much larger scale. It will be motor driven, power being supplied by a plant built at the mill.

Grand Mound, Wash. — NePage, McKenney & Co., Armour building, Seattle, have been awarded contract for electric wiring in cottage being erected at school for girls at this place by the State Board of Control at $2957.

Seattle, Wash.—Walter Lassen and R. D. Colman have opened an electric shop in Bremerton, Wash.

Seattle, Wash.—It is proposed in a council bill to issue and sell $1,250,000 utility bonds for the construction and equipment of third unit to the municipal steam plant on Lake Union of approximately 12,500-kw. capacity.

Seattle, Wash.—An eight-bent concrete building 120 by 80 ft. with full basement, will house the new unit of the power plant to be erected at the Lake Union plant of the city. Plans are being prepared by City Archt. Daniel Huntington. Unit for which bonds have been authorized will cost $1,250,000.

Seattle, Wash. — County commissioners have granted a permit to the Pacific Coast Coal Co. for construction of an electric power transmission line from a point near Renton, along the Renton-Newcastle county road.

Tacoma, Wash.—Ground has been broken for construction of a rubber plant for the Western Rubber Co. which when completed will employ 150 persons.

Tacoma, Wash.—The city council has offered the Tacoma Railway & Power Co. $1,500,000 for its street car lines within the city, providing a vote of the people sanctions the purchase. Under the offer the railway company would also agree to finance a loan of $1,000,000 to the city for the purpose of putting the lines in first class condition. In the past the railway and power company has placed a valuation of $6.000.000 on its lines. The action of the council follows a recommendation of a committee of citizens appointed to consider the street railway problem. This committee decided that the lines would be unable to pay expenses under any fare that the people would stand.

Tacoma, Wash.—The City Council has announced a special election to authorize the purchase of the Lake Cushman power site and to issue $300,000 in bonds for construction.

Chico, Cal.—Preliminary steps have been taken toward the construction of a municipal electric system power generating plant. It is planned to erect a power plant in the canyon capable of generating 3000 hp. The construction of two plants will also be considered.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number given.]

Electrical Material (30,064).—The agency is desired by a man in France for the sale of electrical, sanitary and plumbing material. Correspondence should be in French. References.

Electrical Conductors (30,032).—A street railway company in Spain wishes to receive catalogs of materials such as rails, overhead construction and electrical conductors. Correspondence should be in Spanish.

Electrical Equipment (30,040).—A firm in England desires to act as agent for the sale of engineers' tools and electrical equipment. Quotations should be given f. o. b. American port or c. i. f. English port. Payment, cash against documents. Reference.

Electrical Appliances (30,069).—The purchase and agency is desired by a firm in Belgium for the sale of electrical appliances, such as switches and sockets, wrought iron and steel tubes and fittings, malleable-iron fittings, and gun metal and brass fittings for gas, water, and steam, copper and brass wire, sheets, bar rods, etc. Quotations should be given c. i. f. Antwerp. Correspondence may be in English, but catalogs should be in French if possible. References.

PROPOSALS

Electric Wiring.—Bids will be received by the Sisseton, S. D., Independent School District for the heating, plumbing and electric wiring including electric time program clock and fire alarm system. Frank F. McKenna, clerk.

Electric Light Plant—Bids will be received Aug. 8 for labor and materials required in the construction of an electric light plant for Beresford, S. D. The work is divided into three parts: part 1, brick and tile building; part 2, electric station equipment, consisting of furnishing and erecting two 120-hp. Diesel and semi-Diesel type oil engines, direct connected to two 100-kv-a. generators, also switchboard, constant current transformers, and part 3, pole line, consisting of furnishing and erecting poles, wires, transformers. Address Y. M. Yorker, city auditor.

Pumps—Bids will be opened Sept. 3 for both centrifugal and turbine type pumps to be installed in the pumping station, Kansas City, Kans. Plans and specifications are being prepared for a 50,000,000-gal. capacity pump.

INCORPORATIONS

Brooklyn, N. Y.—Eisenhut Storage Battery Co. Capital, $10,000. To manufacture storage batteries and other electrical products. Incorporators: O. F. and C. Eisenhut, and G. T. Egensteimer, 804 Seneca avenue.

Hadley, N. Y.—Hadley Light & Power Co. Capital, $25,000. To operate a local light and power plant. Incorporators: J. H. Smead, W. Fowler, and J. J. Breen, Hadley.

New York, N. Y.—Portable Electric Current Co. Capital, $2,000,000. To manufacture storage batteries and other electrical specialties. Incorporators: L. B. Kanter, W. A. Blank and C. B. Plante, 761 Lincoln place, Brooklyn.

New York, N. Y.—Mechanical Stokers Corp. Capital, $100,000. To manufacture stokers and other furnace appliances. Incorporators: H. H. Van Aken, M. C. Flanagan and G. B. Sleigh, 31 Nassau street, New York.

New York, N. Y.—Morison Electrical Supply Co. Active capital, $55,000. To manufacture electrical supplies. Incorporators: G. W. Harris, A. H. Abbott, and C. T. Morison, 515 West 187th street.

New York, N. Y.—Victory Engine Co. Capital, $50,000. To manufacture engines, motors, etc. Incorporators: C. O. Assmus, C. H. Atkins, and M. A. Farley, 28 Sterling place, Brooklyn.

Troy, N. Y.—Rensselaer Electrical Supply Co. Capital, $25,000. To manufacture electrical supplies. Incorporators: R. G. Finucane, C. F. W. Kaelber, and A. R. Page, Rochester.

Glenfield (Lewis County), N. Y.—Otter Creek Power Corp. Capital, $35,000. To operate a local power plant. Incorporators: H. S. Lewis, H. D. and G. L. Cornwall, Beaver Falls.

Newark, N. J. — Newark Motor Products Manufacturing Co. Capital, $100,000. To manufacture motors and other electrical products. Incorporators: Otto and H. J. Weber, and Albert J. Farmer.

Philadelphia, Pa.—Railways Electric Equipment Co. Capital, $2,000,000. Incorporated in Delaware to manufacture electric railway equipment and appliances. Incorporators: James F. Bohen, Henry McCarthy and Herbert W. Andrews, all of Philadelphia.

Seattle, Wash. — Seattle Electric Washer Co. has been incorporated by Thomas A. Gaynor et al., for $10,000.

Malone, Wis.—Malone Light & Power Co. has incorporated with a capital of $25,000, and will build an electric plant. John L. Beau, Frank Clark and others are interested.

Personal

Matthew S. Sloan New President of Brooklyn Edison—David C. Rosetahl Joins B & K Manufacturing—Changes

F. M. HAMILTON, superintendent of the department of accident investigation of the Puget Sound Traction Light & Power Co., Seattle, is making a business trip to Philadelphia.

E. J. McILRAITH, formerly superintendent of ways and structures with the Puget Sound Traction Light & Power Co. at Seattle, has been appointed to the position of engineer in charge of maintenance with the Philadelphia Rapid Transit Co.

H. G. BAKER, for the past year connected with the new business department of the Western Colorado Power Co., Salt Lake City, a subsidiary of the Utah Power & Light Co., has resigned to become manager of the Clark Electric Co., with headquarters at Tooele, Utah.

S. L. SHUFFLETON, formerly chief of construction for Stone & Webster in the Seattle district, is now western manager for Stone & Webster at San Francisco. Leslie Coffin, formerly manager for the Puget Sound Traction Light & Power Co., at Bellingham, Washington, and who went to Hog Island for Stone & Webster, is now assistant western manager for Stone & Webster at San Francisco.

H. J. GILLE, sales manager, E. A. Batwell, publicity agent, and Capt. N. W. Brodkett of the legal department of the Puget Sound Traction Light & Power Co., have returned to Seattle from a meeting of the Pacific Coast Committeemen of the National Electric Light Association held at San Francisco for the purpose of arranging for the convention of the association to be held in Los Angeles next May.

MATTHEW S. SLOAN, who is at present operating manager of the New York Edison Company, has been elected president of the Brooklyn Edison Co. following the resignation of N. F. Brady from that office. Mr. Brady continues as chairman of the board and the executive committee. Mr. Sloan has been assistant to the president of the Birmingham Railway, Light & Power Co., and vice-president and general manager of the New Orleans Railway & Light Co.

A. E. KAISER, who for more than twenty-three years has been connected with the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., has been appointed director of production. His experience with the company includes the paint department field and armature machining, winding, assembling, general foreman's offices, rate, central production and storekeeping departments. After spending three years in the latter department he was again called to the office of the works' manager for one year, after which he was appointed assistant director of production in 1912.

PROFESSOR A. P. LITTLE, formerly of the Bureau of Standards, who came to Yale University during the past year in connection with the Signal Corps Training School for officer candidates, has been appointed professor of electrical engineering in the Colorado School of Mines.

F. F. McKINNEY has joined the copy staff of Brooke, Smith & French, Inc., advertising agents of Detroit. During the war he served as an ensign in the navy and since the armistice has been with the advertising department of the Cadillac Motor Car Co. Previous to his enlistment in the navy, Mr. McKinney was engaged in the newspaper business.

F. C. CHAMBERLAIN, for the past six years district engineer of electric operations for the properties of Henry L. Doherty & Co. in the western district, has been appointed general manager of the Richland Public Service Co., Mansfield, Ohio, succeeding R. E. Burger. Prior to his connection with the Doherty organization, Mr. Chamberlain was with the American Gas & Electric Co. at Wheeling, W. Va., and for about four years previous to that time he had been in the New York office.

DAVID C. ROSETAHL, formerly with the National X-Ray Reflector Co., New York City, has become associated with the B & K Manufacturing Co., New Britain, Conn., in the capacity of general sales manager of the portable lamp department. Mr. Rosetahl has been identified with the electrical fixture and portable lamp trade for the past 12 years, having represented such well known concerns as Sampson Bronze Co., J. B. McCoy Co., Sterling Bronze Co., of New York City. While in the employ of the National X-Ray company he acted as sales agent for the entire lower east side of New York City, where he met with great success in the distribution of lighting fixtures, portable lamps and National X-Ray reflectors, and his appointment as general manager of B & K company is a valuable addition to its staff.

STEPHEN C. POHE, who for the past year has been general manager of the Penn Public Service Co., Clearfield, Pa., is now vice-president of the operating companies controlled by the Pennsylvania Electric Co. of New York City, with offices at Clearfield, Somerset and Johnstown, Pa. Mr. Pohe will make his headquarters at Johnstown, where general offices of the companies have been established. He will direct the operating department of the system from that point. Mr. Pohe resigned as manager of the Columbia & Mountour Electric Co. and of the Northumberland Gas & Electric Co. at Bloomsburg, Pa., in 1918, to become general manager of the Penn Public Service Co., from which position he has been advanced. He has been prominently identified with the affairs of the Pennsylvania Electric Association, and was elected president of that organization in 1915.

Obituary.

NEAL KENT, for many years supply salesman for the Manhattan Electrical Supply Co., died recently at his home in Chicago. Mr. Kent was one of the best known and highly esteemed men of the industry in this section, and his sudden death came as a surprise to his many friends in the industry. He is survived by his widow and one daughter.

JOHN C. RODGERS, 75 years old, a prominet contractor of New York City, died on July 24 at his country home at New Rochelle, N. Y. Mr. Rodgers was engaged in the contracting business for forty years. He built portions of Riverside drive and the old subways in New York City, the West Shore Railroad and the Pennsylvania Railroad. He was the sole contractor for the La Chien Canal in Canada, the New York speedway, the Madison avenue bridge in New York City, and the Niagara Falls power tunnel.

LAVERNE W. NOYES, president of the Aermotor Co., Chicago, died on Thursday, July 24, after an illness of many weeks. He was widely known as an inventor and philanthropist. He was born at Genoa, N. Y., Jan. 7, 1849, and was graduated from the Iowa State College with a B. S. degree in 1872. In 1879 he moved to Chicago and patented a wire bookholder, of which he was the sole maker. In 1887 he invented several harvesting machines and later perfected the first steel windmill for the Aeromotor Co., of which he was the head. In 1914 he patented the Auto-Oiled Aeromotor. He designed and built the first steel towers for windmills, and also introduced the first towers for electric transmission. The deceased is survived by an only sister.

JOSEPH WILLIAMS, treasurer of the New York Edison Co., whose home was at 440 Riverside Drive, died on July 23 at Santa Monica, Cal., where he went about July 1 to recover his health, which had been failing for about six months. Mr. Williams was born in New York City sixty-one years ago. In 1873 he entered the employ of Spencer Trask & Co., bankers. In 1890 Mr. Williams was elected assistant treasurer of the Edison Illuminating Co., of which Mr. Trask was president and which was Thomas A. Edison's first venture in electric lighting in New York City. Three years later he became treasurer. When the New York Edison Co. was established in 1901 Mr. Williams was elected assistant treasurer of that company and was elected treasurer in 1910.

For the Readjustment Period—What?

XLVII.

Today's Need — More Business

Today you are in business. Business gets slow. You lose customers. You see the stark, grim wolf of failure creeping 'round your corner, headed for your door. You must do more business.

Will you go and drag customers in? Will you travel 'round and tell your people of your plight and try to get them to patronize you out of pity? What chance do you stand against the punishing advertising of your competitors?

No chance at all—unless—and this is your only salvation—you advertise with them—advertise against them—or go to the wall!

You must race at their pace or you're out of the running.

And just as rocks and rifles enable a man to strike a harder blow than the impact of his fist or the kick of his boot—and at a far greater distance than the length of his arm—so consistent advertising enables a man to persuade more powerfully than by speaking to a few neighbors—enables him to reach untapped sources of patronage at wonderful distances—rather than depend upon precarious transient trade or pitying acquaintances.

Rifles are but perfected stone throwers. And advertising is the modern weapon—the rifle of big business. It is the better way and the only way to bring protection from and to bring down big game!

This little screed, which is copyrighted by the Press Publishing Co., has in it a thought or two of value for the progressive manufacturer or merchant. To meet the rising tide of expense "Doing More Business" is the only effectual safeguard.

C. A. TUPPER *President*
INTERNATIONAL TRADE PRESS, INC., CHICAGO

Financial News

Utility Securities Highly Desirable.

Samuel Crowther, in System Magazine, calls attention to the wisdom of investing present day surpluses in conservative securities. Sound public utility securities meet the requirements which he regards as highly desirable. He says:

"The ability of any individual or corporation to meet adverse conditions is measured by its financial resources that remain unaffected by the shifting conditions. If prices drop, inventory values will be cut, bookkeeping reserves be of almost no use, and any speculative bonds will be worse than useless because their value will vanish at the first storm cloud. The only resource which then can easily be liquidated will be the 'conservative' issues.

"There exists a rare opportunity today to build up a sound reserve. The so-called 'gilt-edged,' long-term, low-interest-bearing bonds are selling at high interest rates. It is unlikely that they can go very much lower. They can hardly be affected by any known business calamity and their value must increase with the shaking down of the years.

"They are the investment for a man who desires to be in business five or ten years from now when the world has resumed more or less normal functioning."

Federation of British Industries After World's Markets.

The Federation of British Industries, which is composed of over 900 of Britain's biggest manufacturers and manufacturing associations, has formulated plans for an overseas organization which contemplates the appointment in every market of the world of a commissioner, assisted where advisable by expert advisers and sub-commissioners. In this connection, the American Chamber of Commerce in London advises that the Federation has issued a map of the world which has been divided into 21 areas. Several of the commissioners for these areas have already been appointed.

Accompanying the map is a valuable analysis of the imports of the various commercial areas in 1913. The figures give the total imports and the amount of imports from the United Kingdom, thus showing clearly where British trade needs stimulating. It is the purpose of the Federation to explore all the possibilities of these markets and to further British trade in all possible ways.

The Oversea Trade Department of the Federation is a separate organization which is divided into eight geographical sections, organized as intelligence centers for the various territories. The purpose of this department is to provide a service run by manufacturers for manufacturers, capable of giving assistance and information of every kind promptly and efficiently to every manufacturer who desires to export his goods or import his raw material.

The American Chamber of Commerce in London says that the Federation of British Industries is a very high class, powerful organization and can be counted on as very likely to accomplish the objects it goes after.

Restoration of Public Utility Credit.

In view of the fact that President Wilson in his recent message to Congress called attention to the need of constructive action in regard to public utilites, and also that the newly organized Federal Electric Railways Commission is investigating the street railway situation with a view to making recommendations, an analysis of the public utility situation has been made by Stone & Webster of New York, Boston and Chicago.

"It is our belief that despite the difficulties of the war period there is a solid basis for optimism in the public utility situation," the analysis states. "The question of restoring public utility credit has become definitely recognized as one of the most important domestic matters to be solved during the coming period of readjustment. This credit must be reestablished on a basis that will insure to this great industry, representing an investment of $12,000,000,000, not only an adequate return on the capital already invested but also sufficient safeguards for the new capital that must continually be attracted so that utilities may serve in the growth of the nation.

"The service rendered in supplying light, power, gas and transportation in our cities and for our manufactories is as fundamental to the industrial and economic life of this country as are our railroads, mines, oil fields, agricultural lands and factories. It is estimated that the urban population served by street railways and interurbans is upwards of 43,000,000 and that they move over 20,000,000,000 passengers annually.

"Yet this great group of public service companies, serving national needs, shouldering all the higher costs of labor, taxes, materials and supplies occasioned by the war, received practically no financial aid from government sources and no assistance in a comprehensive plan for effective and speedy relief in the way of securing higher rates and fares—except as could be worked out by each individual company through the slow method of application to the state commissions, municipal authorities, and referendum vote.

"Capital had to be secured to take care of maturing obligations, amounting in 1918 to over $225,000,000, at interest rates in many instances much higher than the fixed rate of return allowed on the investment by franchises and other regulations, and with the temporary sacrifice in many cases of a large part of the equity value. In normal years the amount of new money required annually by public utilities for extension to plant aggregates from $600,000,000 to $700,000,000. During the period of the war these requirements were cut to approximately $250,000,000 per annum, but this money had to be raised in addition to the maturing obligations.

"For the year 1918 it was estimated that the net operating revenue of the traction companies in the United States approximated $70,000,000, with only a few months of the war labor board awards reflected in expenses. Increases in expenses through these awards amount to over $100,000,000 annually. Since we entered the war in 1917, and up to Feb. 1, 1919, companies operating some 4,900 miles of track, representing approximately one-tenth of the total street railway mileage, have gone into receivers' hands, that about 500 miles of track have been completely abandoned, and that foreclosure sales of twenty-three roads, representing 524 miles of track, have resulted."

Earnings Edmonton Public Utilities Show Improvement.

Edmonton public utilities show a net surplus for May of $2345, compared with a net deficit for the same month last year of $3549. The net surplus for the five months (inclusive of the street railway deficit) amounts to $62,233, against $33,809 for the corresponding period of 1918. Net surpluses for the five months of the respective departments are as follows:

	1919.	1918.
Electric light	$ 66,056	$54,131
Telephone	21,356	13,845
Water works	14,246	10,746
Total	$101,659	$78,724

The street railway deficit is $39,425, as compared with $44,914 last year, leaving, as already stated, a net surplus of $62,233 on the combined utilities, as compared with $33,809 in 1918.

Electrical Review

l. 75. No. 6. CHICAGO, AUGUST 9, 1919 Three Dollars a Y

Electrical Review

WITH WHICH IS CONSOLIDATED WESTERN ELECTRICIAN AND ELECTROCRAFT.

VOL. 75—No. 6. CHICAGO, SATURDAY, AUGUST 9, 1919. PAGE 223.

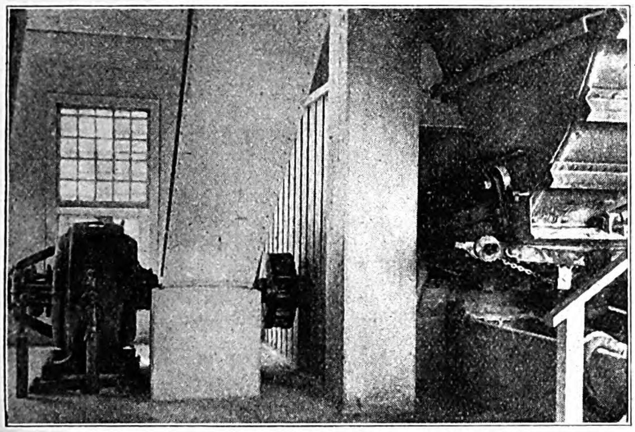

Fig. 1.—60-cycle, 250-hp., 700-r.p.m., 440-volt Driving Williams Mill, in Plant of Southwestern Portland Cement Co.

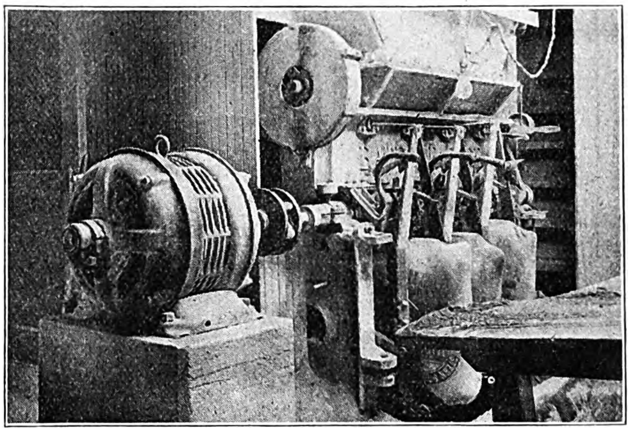

Fig. 2.—15-hp., 1140-r.p.m. Westinghouse Motor Driving Sacking Machine.

Electric Drive in California Cement Mill

Motor-Driven Machinery Proves Successful in Plant of Southwestern Portland Cement Co. at Victorville, Cal. —Central-Station Service Used — Description of Process

APPLICATION of electric drive in the operation of a cement mill, and the advantages to be derived therefrom, are unusually well exemplified in the plant of the Southwestern Portland Cement Co. at Victorville, Calif. This town is in the southwestern part of the state, about 100 miles from Los Angeles on the Santa Fe Railroad, the tracks of which pass by the plant, affording a convenient outlet for the finished product.

This mill has an output of 300,000 bbls. a year of portland cement, and employs approximately 80 people. All of the buildings are of substantial concrete construction built to withstand the severe conditions imposed by the heavy machinery installed.

Water for the wet process system of manufacture, and for use throughout the mill, is raised to a reservoir on a hill back of the plant by a 15-hp. motor-driven triplex pump. Rock and shale are brought to the mill from the quarry which is located 7 miles distant, by a steam locomotive hauling trains of cars that have two compartments or hoppers which are dumped one at a time into the crusher.

Electric current is purchased from the Southern Sierras Power Co., thus relieving the company of the expense and trouble incident to the operation of a power plant. Current is received at 33,000 volts and stepped down to 440 volts, for application to the various motors installed throughout the mill.

Transformers and switching apparatus are of the outdoor type, located immediately adjacent to the mill. The current is taken from here to a 7-panel marble switchboard, built by the Westinghouse Electric & Manufacturing Co., from which it is distributed to the various power and lighting circuits in the mill.

Lime rock is delivered from the hopper cars direct to the crusher, but a reserve pile of crushed stone, amounting to between 3000 and 5000 tons, is maintained sufficient to keep the mill operating for a period of approximately 30 days. This reserve is maintained in the event of any accident, such as a washout, crippling the railroad service from the quarry to the mill.

The crusher and Williams mill are driven by a 250-hp. Westinghouse type CW wound-rotor type motor—as shown in Fig. 1—which break the rock into pieces about the size of a walnut or a little larger. From here the rock is elevated to a storage bin by a bucket elevator, driven by a 30-hp. motor, and thence by belt conveyor to the pulverizing house. Up to this time no water has been put with the rock except what is thrown on at the time it goes into the crusher, which is done with a hose to eliminate whatever dust rises during that process.

During the process of pulverization, water is added again for the purpose of eliminating the dust. After being thoroughly pulverized, the mixture is taken to the slurry tanks where it is kept in motion by air agitation until ready for admission to the kiln.

There are six slurry tanks served in pairs by ele-

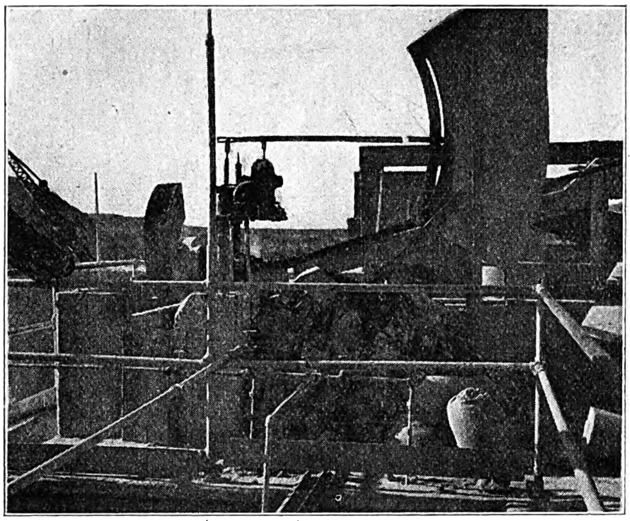

Fig. 3.—¼-hp., 440-volt., 1725-r.p.m. Westinghouse Single-Phase Motor Driving Slurry Feed Control Dipper.

vators operating at a speed of approximately 88 ft. per min., for elevating the mixture from the pulverizing house tanks, and driven by a 7½-hp., constant-speed motor.

After the mixture has been thoroughly agitated it is transferred to the slurry tanks nearest the kiln. From here it flows into a sump and is delivered to the kiln by a motor-operated measuring device illustrated in Fig. 3, which shows the rear of the scale. The dipper is made in the shape of an S, the outlet being in the center. By raising and lowering the dipper in the sump the amount of slurry entering the kiln can be controlled. The dipper is driven by an extended shaft, provided with two universal joints from one of the elevators, and is raised and lowered by a ¼-hp. 1725-r.p.m. motor by means of remote control from the clinker end of the kiln. The large scale is visible to the operator at the clinker end and he can feed the proper amount of mixture to the kiln and watch his fire at the same time.

The rotary kiln is approximately 200 ft. long and 20 ft. diam., lined with fire brick and heated by an oil burner to a temperature of about 2500°, which is measured by a radiation pyrometer. It is driven at a speed of 1 r.p.m. by a 50-hp., type CW, 700-r.p.m.

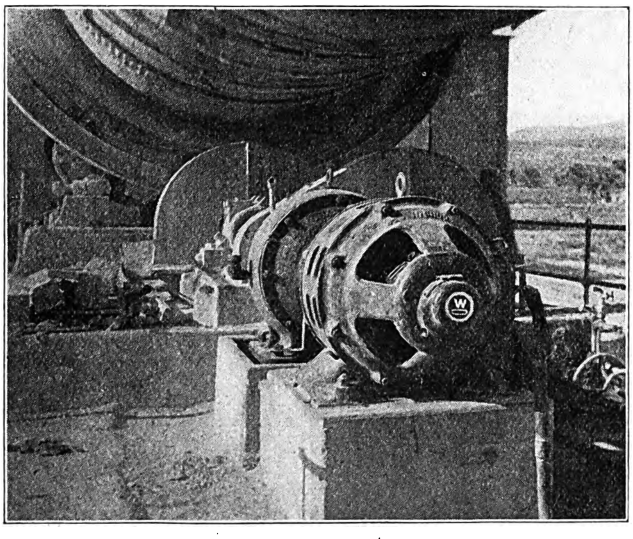

Fig. 4.—50-hp., 440-volt, 60-cycle, 3-phase, 700-r.p.m. Motor Driving Rotary Kiln Through Foote 14 to 1 Reducer; Speed, 1 r.p.m.; Double Reduction, 48 to 1.

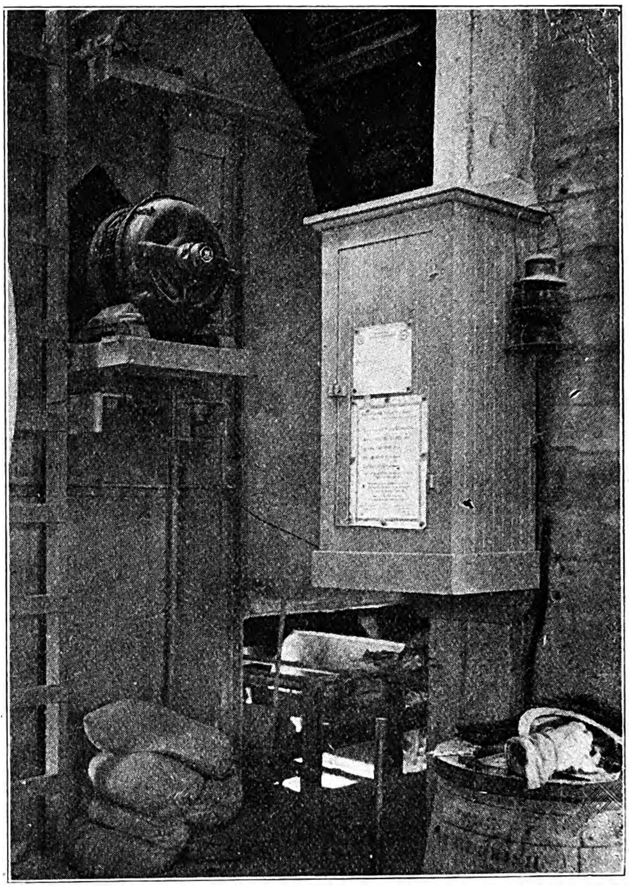

Fig. 5.—7½-hp., 680-r.p.m., 440-volt, 60-cycle Motor Driving Clinker Elevator.

motor through Foote reduction gears, as shown in Fig. 4. The kiln is elevated at the raw end so that, as it rotates, the mixture will travel toward the clinker end. Upon coming from the kiln the clinker falls about 20 ft. into a pit to allow it to cool somewhat. It is then elevated by the clinker elevator which is driven by the 7½-hp., 680-r.p.m. motor, shown in Fig. 5, to an automatic scale and dumped into the storage bin. From the storage bin the clinker is transferred by means of a locomotive crane, with a clamshell bucket, to a bin from which it is fed into the finish mill. The locomotive crane is also used for mixing the clinker, as it will vary somewhat in quality. After being ground and analyzed by the chemical department, it is ready for the packing house, to which it is carried on a belt conveyor over a weighing machine, which automatically records the number of barrels that pass.

From the storage bins, the cement is taken to the

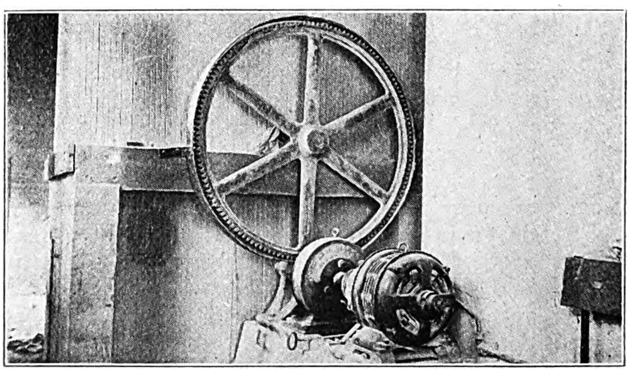

Fig. 6.—7½-hp., 10-pole, 680-r.p.m. Westinghouse Motor Driving Sack Cleaner Through Foote Reducer.

sacking machines, shown in Fig. 2, driven by a 15-hp. motor. A sack cleaner driven by a 7½-hp., 680-r.p.m. motor, through a Foote reduction gear, is shown in Fig. 6. A 15-hp. motor-driven blower, for collecting dust from the sacking and sack cleaning machines, is also used.

The motors are of the 440-volt, 60-cycle, 3-phase, induction type, and were furnished by the Westinghouse Electric & Manufacturing Co., of East Pittsburgh.

This plant was designed and built by L. D. Gilbert, and has been in operation over 3 years, during which time no shutdowns have been experienced due to any trouble with the electrical equipment. It is a model plant from every standpoint and is practically dustless.

UNIQUE NATIONAL ADVERTISING EXHIBIT PLANNED AT NEW ORLEANS.

Successful National Advertising Campaigns, Industrial Relations Campaign and the Neosho Co-operative Advertising Plan to Be Featured.

Information of a most valuable character will be available to those who visit the National Advertising Exhibit, to be held as a part of the 15th annual convention of the Associated Advertising Clubs of the World, at New Orleans, La., Sept. 21 to 25, says a recent bulletin from the advertising association. It is believed that this exhibit will prove of interest to electrical manufacturers, jobbers and utility companies that do extensive advertising.

In addition to the fact that this year's advertising exhibit will take a new form, embracing complete showings of several actual advertising campaigns, it is also announced that at stated hours those who planned and executed the campaigns shown will be on hand to explain them and to answer any questions which are not answered to the complete satisfaction of the visitor by the exhibits themselves.

Several campaigns are to be shown; there will be national, semi-national, territorial and local campaigns. Advertisements from publications and from all other mediums used, as well as "follow-up" matter employed in the campaigns will be shown and explained, and Joseph S. Potsdamer, of Philadelphia, chairman of the exhibit committee, has declared that it will be such an exhibit and explained in such interesting detail, as to bring notebooks from the pockets of those who see it.

In addition to these campaigns, two other features of importance are being planned. One of them, following the chief theme of the convention, will show campaigns which have been used by manufacturers, merchandising establishments and other employers, in gaining the co-operation of their employes. This section will be supplemental to the plan to have a labor leader and a man equally representative of capital present what they believe to be the terms upon which capital and labor can agree so as to insure increased production and thereby insure continued prosperity. Samuel Gompers, president of the American Federation of Labor, has accepted a place on the program.

The other feature of importance will be a complete exhibit showing how the Advertising Club of Neosho has built up the business of Neosho through a plan of co-operative advertising and by co-operation among the merchants, to insure that all of the advertising done is so truthful as to insure that the customer who comes to Neosho will desire to make Neosho his regular trading point.

CIVIL-SERVICE EXAMINATION FOR ELECTRICAL ENGINEER, SIGNAL CORPS.

Examinations for Electrical Engineer, $2400 to $3600 a Year, and Assistant Electrical Engineer, $1800 to $2400 a Year, to Be Held Sept. 16.

The United States Civil Service Commission, Washington, D. C., announces open competitive examinations for the positions listed above, for men only. Vacancies in the Signal Service at Large at the salaries indicated, and in positions requiring similar qualifications will be filled from these examinations. Certification to fill the higher-salaried positions will be made from those attaining the highest average percentages in the examinations.

The duties of these positions comprise the development and design of electrical equipment and especially Signal Corps storage batteries, or the administration of commercial telephone systems and installation of Government-owned systems.

Competitors will not be required to report for examination at any place, but will be rated on the following subjects: (1) education, training, and experience; (2) publications, reports, or thesis (to be filed with application). Under the first subject competitors will be rated upon the sworn statements in their applications and upon corroborative evidence.

For the position of electrical engineer, applicants must have graduated with a B. S. degree, preferably in electrical engineering, from a college or university of recognized standing, and also have received the E. E. degree after having completed the required courses of resident or nonresident work; and, in addition, have had at least two years' experience devoted in major portion to work involving one or more of the following subjects: Testing of electrical instruments or apparatus; research concerning radio apparatus; calibration and standardization of electrical meters and apparatus; teaching or theoretical and analytical research in physics, electrical engineering, telephony, or telegraphy; direction or management of electrical or physical laboratories; acceptable consulting engineering practice in telephony, telegraphy, radio, or electrical engineering other than power plant.

For the position of assistant electrical engineer, applicants must have received at least 59 credit hours for resident study in a college or university of recognized standing; and have had at least two years' experience devoted to the testing, standardization, and calibration of electrical instruments or apparatus; teaching in physics or electrical engineering; as laboratory assistant in physical or electrical laboratory; or in analytical electrical research or radio production or inside plant telephonic consulting engineering.

Under subject two, applicants must submit with their applications any publication or report prepared by them showing their fitness for the position for which they apply; or, in lieu thereof, they should prepare and submit with their applications a technical thesis on the design and development of some piece of apparatus for the Signal Corps.

Applicants will be admitted to these examinations regardless of their age; and regardless of their residence and domicile.

Further particulars regarding this examination are given on Circular 394 issued by the commission. All applications with statements as to training, experience, etc., and with reports, thesis, photographs, etc., must tomer who comes to Neosho, Mo., desire to make it his regular trading point.

Practice in Making Electric Utility Appraisals

Practical Methods Used in the Inventory of Land, Buildings and Outside Plant—Systematic Planning of the Inventory—Forms Used in Gathering Field Data

By CHARLES W. McKAY

THE previous articles in this series have confined themselves to a discussion of the general problems involved in electric utility appraisement. The present article, and those immediately succeeding, will deal with the practical problems involved in taking the actual inventory of an electric utility company's property.

From the article in the issue of the ELECTRICAL REVIEW for June 28, 1919, it will be remembered that the Direct Construction Cost is divided into two general divisions: Cost of Inventoriable Property and Incidental Construction Expense. The Cost of Inventoriable Property is again subdivided according to the major classifications of an electric utility company's physical property. These major classifications are:

1. Land.
2. Buildings.
3. Pole lines.
4. Conduit system.
5. Aerial wire and cable.
6. Underground wire and cable.
7. Transformers.
8. Central-station equipment.
9. Tools.
10. Supplies, etc.

Before taking up a discussion of the detailed methods to be employed in the actual inventory of the items represented by these major classifications it may be well to briefly discuss the general *modus operandi* of taking and recording field data.

The reader will doubtless appreciate that the volume of data involved in the appraisement of even the smallest electric utility plant is so great as to necessitate the utmost care not only in acquiring the data, but, also, in so recording them as to be subsequently intelligible. Otherwise the completed inventory would only present a hopelessly confused mass of well-nigh useless data.

Making Rapid and Accurate Utility Appraisals.

UTILITY rates are nowadays usually set after a valuation of the utility company's property has been made, this being to set at rest charges often loosely made that the company is earning big returns on watered capitalization. Even in emergency rate cases, where there is no time to make a complete valuation of the plant, provision is commonly made for a later revision of the rates when a subsequent valuation shows them to be too high or too low. In general, it may therefore be said that valuation is a quite usual concomitant of utility rate cases, and, because of the present exceptional importance of these cases, valuation of utility properties is a very timely topic for the utility manager.

In this article Mr. McKay discloses many valuable facts and makes important suggestions for carrying on an appraisal of electric utility properties, all based on his many years' experience as an appraisal engineer. The ideas and forms he suggests will be found to save much time and money in making the inventory and to increase its reliability decidedly.

This article is the fourth of a series of twelve on valuation and rates. In the first article, in the issue of May 17, Mr. McKay gave a general introductory discussion of modern utility regulation; his second article in the June 7 issue, included definitions of the principal terms used; his third article in the June 28 issue discussed reproduction cost as the basis of appraisement. The next article will consider appraisement, or valuation, of the inventory discussed in the present article. Mr. McKay will gladly throw additional light on any of these matters, if inquiries are addressed to him in care of the editor of the ELECTRICAL REVIEW.

There are certain preliminary steps which must be observed in the appraisement of any electric utility property to make it systematic and economical. These steps may be summarized as follows:

1. Determination of the purpose of the appraisal.
2. A general survey of the property by the engineer in charge of the appraisal.
3. A careful investigation of the utility company's records.
4. A review of the appraisal requirements of the public service commission, under whose jurisdiction the company operates.
5. A careful determination of the various types of construction used by the company whose property is under appraisement and the subsequent preparation of suitable field forms to record the inventory data.
6. Selection of employes for performing the task of inventory.

Determination of the Purpose of Appraisal.—Electric utility appraisals are used for various purposes and to avoid unnecessary refinement of detail in preparing the appraisal it is most necessary that the appraisal engineer shall make a careful study of the ultimate uses of the appraisal. The various uses to which electric utility valuations are put may be summarized as follows:

1. For presentation before a regulatory body in rate cases.
2. For determining fair value as a basis of subsequent financing.
3. For use as a basis for tax adjustment.
4. For accounting purposes.

Our present problem is confined largely to item 1—the preparation of an appraisal for presentation before regulatory bodies in connection with rate cases. It is well, however, for the appraisal engineer to make every effort to so prepare the appraisal that it may be used for accounting, tax adjustment, financing, and other purposes.

Survey of Conditions.—Knowing the use to which the appraisal is to be put, the engineer in charge is equipped to prosecute the actual work of appraisement. To do so intelligently he must first make a general inspection of the property to be appraised, noting the geographical layout of the plant and determining, in so far as possible, the construction history of its component parts.

It is most important that this preliminary survey be made with the utmost care. A study of the geographical layout of the plant—especially if the property is a large one—will subsequently enable the appraisal engineer to so plan his work as to effect many economies in the cost of appraisement.

Investigation of the Company's Records.—After completing the preliminary survey the appraisal engineer should carefully review the company's records and map files. If the records are reasonably accurate, they may often be used as an aid to the field work. Maps of the plant, if accurate, may be used as a guide for the field engineers. The use of such maps frequently obviates many days work in the field in preparing ground layouts.

In reviewing the company's records the appraisal engineer should also determine to what extent these records may be used as a basis for building up the unit costs. *Reproduction* unit costs based upon *actual* costs afford the most conclusive evidence for presentation before state commissions.

Review of Commission Requirements.—If the appraisal is to be used in connection with a rate case —and we assume that it is in our present discussion— it is most important that the appraisal engineer shall thoroughly familiarize himself with the commission instructions referring to the presentation of inventories and cost data. The requirements of various state commissions vary widely and in view of the fact that the readers of the ELECTRICAL REVIEW are scattered all over the United States, it is deemed advisable to confine the present discussion to general, common-sense methods of inventory and appraisement. It is thought, however, that the appraisal methods presented in this series are flexible enough to facilitate their ready adaptation to the peculiar requirements of any commission.

In undertaking a specific appraisal problem it is most important that the engineer in charge shall carefully review the instructions of the local commission —otherwise he might subsequently be confronted with the embarrassing problem of entirely revamping his data to meet the commission's requirements.

Preparation of Field Forms.—The problem of preparing suitable forms for recording and summarizing the inventory data is a difficult one and its importance cannot be exaggerated. This whole subject will be discussed in detail in a subsequent portion of this installment. For the present suffice it to say that time expended in the preparation of suitable forms is well spent and should result in a minimum cost of appraisement and a maximum usefulness of the completed valuation.

Selection of Appraisers.—Many electric utility companies adopt the practice of employing a skilled appraisal engineer—and possibly one or two of his assistants—to supervise the preparation of the inventory and appraisal and to co-operate with counsel in the task of presenting the rate case before the state commission. These companies prefer to furnish the necessary help, in the way of field inspectors and office men themselves—the thought being that a sufficient number of men can be spared from the operating forces to undertake this work without impairing the operating efficiency and thus minimizing the cost of appraisement.

The adoption of this policy is questionable, but where it is adopted the task of selecting the men should be left entirely to the appraisal engineer.

In this connection it is interesting to note that the best operating employes often make the poorest appraisers. The engineer in charge of the appraisal is obviously best qualified to pick the men for his own peculiar needs.

FORMS FOR RECORDING THE INVENTORY DATA.

Having completed this general discussion of the steps preliminary to the actual task of taking the inventory, we are now ready to consider ways and means of recording the inventory data. The various plant classifications will be discussed in the order enumerated in the foregoing recapitulation—the first item being land.

Land.—It is most important that the land, owned by an electric utility company, be completely described so as to avoid subsequent embarrassment when the case is presented before the state commission. It is best to base such a description upon the records in the tax assessor's office. Usually such records are readily accessible to the appraisal engineer if he will but take the trouble to state clearly the use to which the information is to be put. Another source for obtaining authoritative information is the office of the commissioner of deeds or county recorder.

The following is an illustration of the form in which land inventories are prepared:

LAND OCCUPIED BY POWER HOUSE OF BLANK ELECTRIC LIGHT COMPANY.

Location: Southeast corner of 8th and Cedar Streets—City of ...., State of ....

Description: Lot No. 3, block No. 13, and that portion of lot No. 2, block No. 13, lying westerly of the easterly line of lot No. 3; Roberts and Randalls subdivision of the westerly addition to the city of ...., ...

Leaseholds and right-of-way are often considered as subdivisions of the land item. To illustrate: A certain company may have a 99-year lease on the parcel of land upon which its central station is erected. In many states a leasehold of this nature may be considered as one of the fixed assets of the company and therefore should be included in the appraisal.

Again, many electric utility companies have certain right-of-way privileges over private property covering the right to occupy such property for purposes of placing poles, underground conduits, etc. Such right-of-way may be frequently included in the appraisal and the value assigned to it will be entirely dependent upon the exigencies of the case in question.

In this connection it should be remembered that the present article is confined specifically to ways and means of recording and summarizing the inventory. We are therefore concerned only with the description of land and the various other major items of physical property—the question of values will be discussed in a subsequent article.

Leaseholds may be described in a manner similar to that suggested for describing the land proper. Right-of-way for pole lines is usually described only by stating the number of poles involved. For instance, if a certain company has 500 poles upon private right-of-way, the inventory right-of-way item will be listed thus:—Right-of-way for 1000 poles @ (unit cost per item of right-of-way) ....

Buildings.—Many of the state public utility commissions have taken the stand that electric utility appraisers are not qualified to testify as to the value of buildings and that this phase of the appraisal problem should be relegated to building contractors or architects. Be that as it may, it is always well for the appraisal engineer to make his own careful inventory of the buildings and subsequently to appraise this inventory—even if it is merely used as a check upon the architect's valuation.

The inventory of buildings should include the following items:

1. Character of building—whether fireproof, slow-burning, non-fireproof, etc.
2. Over-all dimensions—length, breadth and height.
3. Detail of construction of building:
   - (a) Detailed description of foundation.
   - (b) Detailed description of walls.
   - (c) Detailed description of floors.
   - (d) Detailed description of roof.
   - (e) Detailed description of interior finish —if any.
   - (f) Any further general information that will assist in the appraisement of the building.

The description of a building as included in the appraisal should take somewhat the following form:

POWER HOUSE OF BLANK ELECTRIC LIGHT COMPANY.

Fireproof, brick and concrete building, located at the northwest corner of Third Street and Fourth Avenue.

Main building, 100 ft. long by 75 ft. wide by 30 ft. to peak of roof (25 ft. to wall plate).

Addition at north end, 25 ft. by 25 ft. by 15 ft. to wall plate supporting flat roof.

Detailed description: (Give detailed description of foundations, walls, floors, roof, etc., as suggested in the foregoing instructions).

Pole Lines.—The inventory of the outside plant of an electric utility company is obviously the most difficult problem confronting the appraisal engineer,

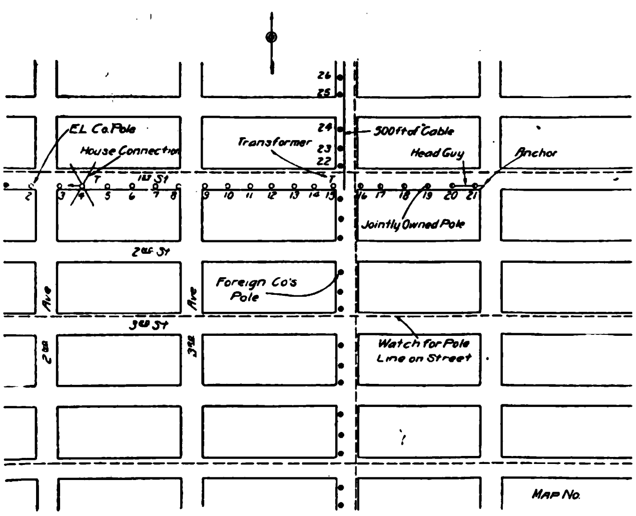

Fig. 1.—Map for Use in Inventory of Aerial Plant.

not that the items themselves are especially complex, but due to the fact that the various pole lines, primary and secondary circuits, underground conduit systems, etc., are scattered over a wide area. It is customary in electric utility appraisal work to undertake this phase of the problem first—weather conditions permitting. The inventory of the land, buildings, central-station equipment, and minor items may be taken at odd times when the weather is unfavorable for outside work.

It is customary to take the inventory of poles, anchors, guys, wire circuits and cables simultaneously. The appraisal engineer should first procure a map of suitable scale—say 400 or 600 ft. to the inch. Upon this map should be indicated the various primary and secondary circuit leads—the map will then serve as a guide for the field inspectors. If the plant to be inventoried is a large one the map should be suitably divided so that all of the inventory gangs will be assigned approximately equal portions.

Various pole leads may be indicated on these maps by a light pencil line and subsequently the field inspectors should show the actual pole locations as found in the field.

Such a map is illustrated in Fig. 1. The light dotted lines indicate the pole leads and the small circles the actual pole locations as found in the field. Guys between the poles are shown by a thin straight line and the anchors by arrows. Poles bearing transformers are indicated by the letter *T*. House connections are indicated by straight lines radiating from the poles.

A map of this character must be used in conjunction with a properly designed form for recording the field data. Such a form is illustrated in Fig. 2.

The following instructions should be helpful in understanding the use of the field form (Fig. 2) and the field map (Fig. 1):

1. Spot poles on the field map, Fig. 1, locating each pole as accurately as possible in relation to street and alley intersections. Poles belonging exclusively to the electric light company should be indicated by a hollow circle. Poles belonging exclusively to foreign companies (such as telephone companies) should be indicated by a filled-in circle. Poles belonging jointly to electric light and foreign companies should be indicated by a circle half filled-in. Spot only those poles belonging to foreign companies upon which there are wires or cables of the electric light company.

In some cases it may be found that the electric light company has in its possession maps giving the above information either in the code just referred to or in some other suitable code for distinguishing between the ownership of poles. In such cases these maps may be used by the field inspectors—providing they are carefully checked in the field and corrections made where the information given on the map is found to be inaccurate.

Before leaving any block make certain that the number of poles shown in the block is correct.

2. Number the poles consecutively as they are spotted (or checked), beginning the series with "1" on each map.

3. Use a separate line on the data sheet for each pole spotted on the map—whether the pole is owned by the electric light company or by a foreign company. Place the pole number in the corresponding ownership column on the data sheet. List only the wire, or equipment, belonging to the electric light company—ignoring all equipment owned by foreign companies.

4. In the column marked "Kind," indicate the material of the pole—using the letter "C" for cedar, "Ch" for chestnut, etc.

5. In the column marked "Setting," use the letter "D" for dirt setting, "R" for rock, "P" for pavement and "C" for pole set in concrete (concrete reinforcement).

6. In the column marked "Tree Trimming," use the letter "L" for light trimming, "H" for heavy trimming, "M" for medium trimming, and "C" for trees cut down.

7. Anchors should be divided into two general classifications, log anchors and patent anchors. Each of these classifications should be subdivided into heavy, medium and light anchors as indicated on the data sheet (Fig. 2). The distinction between heavy, medium and light anchors should be decided by the appraisal engineer before the field work is started and definite instructions should be issued to the field forces.

8. Under the column marked "Cable," give the gauge of the cable and the number of conductors.

The cable measurements (lengths) should be shown upon the map (Fig. 1) as indicated.

9. Under the columns marked "Condition," use the letter "E" for excellent, "G" for good, "F" for fair and "P" for poor. (This phase of the subject will be discussed more specifically in a subsequent installment on Depreciation.)

10. The field inspector should place his name, and the date on which the sheet was filled out, upon each inventory sheet. When several field sheets are used in connection with one field map these sheets should bear consecutive numbers.

11. Where a given pole line extends beyond the limit of the map mark the last pole with a cross inside of a circuit; colored chalk may be used for this purpose. Such a designation will indicate to the field inspector who happens to have the map of the adjoining section that this pole has already been taken—thereby eliminating duplications in the inventory.

12. Transformers should be marked on the map with a "T" opposite the pole on which they are located. In the column of the data sheet headed "Transformers" the size and make of the transformers should be noted.

A set of instructions similar to the foregoing should be issued by the appraisal engineer at the beginning of every large appraisal task. If this is done, and the work of the field inspectors carefully supervised at frequent intervals, the accuracy of the inventory is assured and the possibility of embarrassing mistakes will be obviated.

This method of using a map in conjunction with the inventory sheet has another advantage—it facilitates the ready checking of the inventory by the commission engineer. The advantages of the adoption of this system—or some equally good system—can hardly be exaggerated. Each step of the inventory work is readily identified and even if errors should creep into the work they can easily be corrected.

It is thought from the foregoing rather broad discussion of the method of taking the inventory of poles, anchors, guys, wires, cable and transformers, that the reader will gain a general idea of the method usually adopted in work of this nature. A detailed discussion of this phase of the subject would exceed the space allotted to one article. However, if any questions should arise the author will be very glad to answer them.

Underground Conduits and Cables.—Even more care should be adopted in the inventory of the underground than in the aerial system. This is for the reason that underground systems are very expensive and an error of a few feet in the inventory may result in an appraisal error of several hundred dollars or more.

Another reason for exercising care in making an inventory of the underground plant is that subsurface distribution systems are usually so complicated that it is necessary to employ higher grade men than is the case in the recording of aerial inventories. Care in laying out the work will effect a saving of time on the part of the field inspectors and therefore a saving in expense. In this connection it is interesting to note that one experienced in the inventory of underground distribution systems can record accurately the data for from 50 to 75 manholes a day, whereas a novice in this type of appraisal work could not possibly cover over 15 to 25.

As in the case of the inventory of the aerial system, the combination map and record-sheet scheme is best adapted for insuring speed and accuracy.

Fig. 2.—Sample Field Sheet for Recording Aerial Plant Data.

The appraisal engineer should provide himself with a map showing the location of all the manholes. If such a map is not available, a skeleton map should be made and the manhole locations noted thereon. Information as to the position of the manholes, at least approximately, may usually be had by consultation with some of the older employes of the company whose property is under appraisement. The data, as thus obtained, may subsequently be checked by the field inspectors.

Fortunately, however, most companies maintain reasonably accurate records of their underground systems and these records frequently show not only the location of the manholes, but also information as to the numbers of ducts, locations and sizes of lateral leads and sometimes data relative to the size and gauge of the underground cables.

A typical underground map is shown in Fig. 3. while Fig. 4 illustrates a form of field sheet for recording the data. One of these sheets, obviously, should be made out for each manhole.

To illustrate the correlation of the field map and data sheet—as they are used in the appraisement of an underground system—the various steps necessary to the proper recording of the data for one manhole will be described in detail. Assume that the field inspector has completed his inventory of manholes 1, 2, 3 and 4. Using a 100 ft. steel tape the inspector and his assistant will carefully measure the distance between the center of the cover of manhole No. 4 and the center of the cover of manhole No. 5. It is most important that such measurements shall be accurate, as errors may amount to from one up to several hundred dollars a lineal foot. The best way to insure accuracy is to use surveyor's pins; counting the pins and reading the last measurement on the tape, it is a comparatively simple matter to obtain accurate measurements.

While en route from manhole No. 4 to No. 5 the inspector will note the character of the pavement, or pavements, between the two manholes.

Arriving at manhole No. 5, the inspector will note

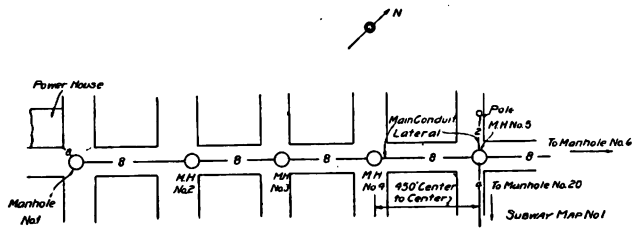

Fig. 3.—Typical Map for Subway Plant Inventory.

the manhole number and geographical location in the spaces provided therefor on the data sheet. The distance between manhole centers, 450 ft. in this case, will also be recorded in the proper place upon the data sheet. Assuming that the manhole covers are located centrally, with respect to the manholes themselves, the method of determining the actual conduit (trench) length will be apparent—deduct the distance between center of manhole cover and manhole wall, in each manhole, from the total center-to-center measurement.

After the cover for manhole No. 5 has been removed, the inspector will leave his assistant on guard on the surface while he descends into the manhole to obtain the necessary data. In this connection it is most important that municipal regulations as to protecting street openings shall be carefully observed. For instance, some cities require a man outside of the manhole to wave a red flag while the manhole is open.

Manholes are usually dirty and to insure the protection of the inventory records it is good practice for the assistant to note the data on the field sheets as it is called out by the inspector in the hole.

The following data should be obtained and noted in the spaces provided therefor:

1. Material of manhole—brick or concrete.
2. Measurements of manhole—length, width, distance from roof to floor and distance from street level to floor.
3. Diameter of cover casting.
4. Distance from center of cover to walls where the ducts enter the manhole—this for the purpose of obtaining actual duct lengths as referred to in a foregoing paragraph.
5. Number of ducts on each wall face, internal diameter of ducts and material of which they are made.
6. Where more than one duct enters a manhole wall the formation of the ducts should be shown on the spaces provided therefor in the manhole diagram. To illustrate: An 8-duct subway may consist of two 4-duct tiles placed one on top of the other, or it may consist of two parallel 4-duct tiles. It is important that the formation of the ducts should be noted, as this has a material bearing upon the cost per trench foot. It requires a wider trench to lay two 4-duct tile horizontally than to place one on top of the other. (It will be noted that the manhole diagram shows the four walls of the manhole folded back in the plane of the manhole floor. This is the simplest and most satisfactory method of diagrammatically picturing the inside of a manhole.)
7. The enveloping material of each subway entering the manhole should be noted. Electric light subway systems are sometimes surrounded by a complete concrete envelope. In other types of construction the ducts are laid on a concrete base and are roofed with concrete while the sides are left unprotected.
8. Care should be observed in noting all branch conduits leaving the manhole. Subsequently these branches should be located and measured.
9. The size of cable—whether 2-conductor, 3-conductor, 6-conductor, etc.—should be noted. The cable diameter should be determined. This for the reason that standard cables of a certain diameter contain a given number of pairs of a given gauge. Knowing the diameter, therefore, it is a comparatively simple task to compute the size and gauge of cable.
19. The amount of manhole slack cable should be determined and the center-to-center measurement (450 ft.) should be increased to allow for the slack.

It will be noted that Fig. 4 calls for some additional data—the nature and method of determining these data will be obvious. A set of instructions similar to the foregoing should be provided to the field inspectors in every large electric utility appraisal.

We have now briefly covered the subject of the inventory of all of the major items of the physical property of an electric utility company—with the exception of central-station equipment, tools, and supplies. In other words, we have covered the more complex and the more difficult—from the standpoint of the inventory—portion of the appraisal. The inventory of the central-station equipment is, of course, most important, but it is concentrated in a comparatively small area, is easily identified and, therefore, easily appraised.

The next article in this series will deal with the *appraisement* of the land, buildings and outside plant. In other words, we will proceed to appraise the inventory we have just completed. The inventory and appraisal of the central-station equipment, tools and supplies may best be treated in one article as it is often possible to make the inventory and appraisement simultaneously. In other words, experienced appraisers can frequently set down the prices opposite the item as they are listed in the inventory, although of course this does not apply to the larger items of

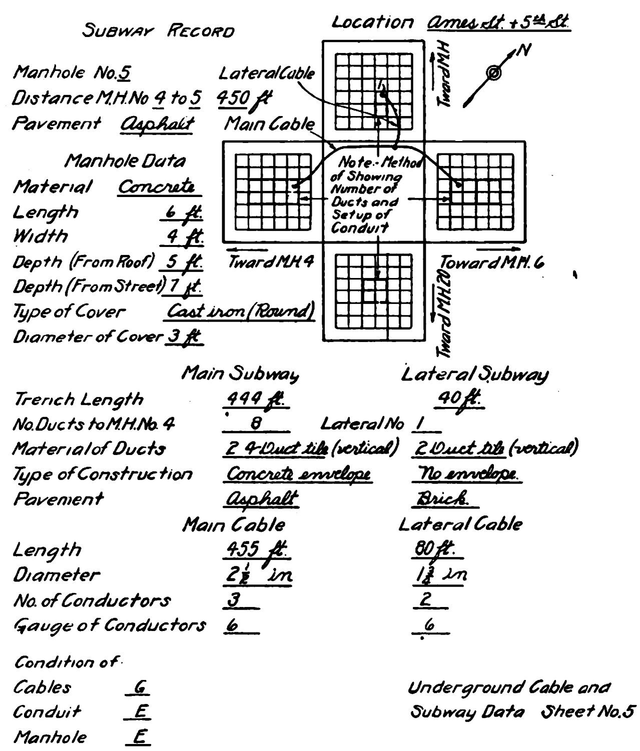

Fig. 4.—Sample Field Sheet for Recording Underground Cable and Subway Data.

central-station equipment, such as engines, turbines and generators.

The author will be very glad to answer any questions regarding this article, or the preceding ones, if addressed in care of the editor of the ELECTRICAL REVIEW.

Central-Station Rates in Theory and Practice

Fifth Article—Apportioning the Demand Charges According to Consumers' Maximum Demands—Assumptions as to Coincidence with Peak Load of Station and as to the Actual Demand

By H. E. EISENMENGER

This is the fifth article of a series appearing weekly throughout practically this entire volume. A general outline was published in the July 5 issue and the first article appeared in the issue of July 12. The first few articles discussed costs in general and showed that the cost of electric service comprises three elements—energy, demand and consumer's costs. Several of the recent articles have treated of various features of the demand costs, which will be continued in a few more installments. After the cost analysis has been completed, the discussion of rates, which depend largely on cost, will be taken up.

PART I—THE COST OF ELECTRIC SERVICE—Continued.

II-A. THE THREE ELEMENTS OF COST.

B. APPORTIONMENT OF THE DEMAND COST BETWEEN THE CUSTOMERS.

3. *Central Station's Peak Extending Over a Certain Period of Time.*[1]

SECTION 30. The exact method of determining the demand cost, as mentioned in the last issue, and as set forth in detail in Insert VI, can of course be used in practice only for larger groups of consumers (for instance, for the power consumers where we can separate the load curves for light and power). An application to individual consumers is entirely out of the question, unless we have to deal with consumers of exceptional magnitude, for instance, a railway company supplied with traction power. For smaller individual consumers the method would be far too complicated.

31. Even if we are satisfied with the consumer's peak responsibility as exclusive basis for the demand—assuming for the moment that this scheme would be commercially feasible—we would discover at the first attempt that it is impossible to determine the time of the central station's peak load exactly to the second or even to the minute. The maximum of the central station's load will extend over a period of perhaps 10 or 20 minutes, or more, at practically constant load, and this peak may even be repeated on several days, during the year. The changes of the central-station load within these peak periods will be so small that the eye cannot detect them on the chart, whereas the load of the consumer during these periods may vary between zero and 100%.

32.. But even if it were possible to discern a certain moment of time of one or a few seconds' duration during which the load of the central station is larger than at any other moment of time and disregarding the statements of Sections 28 and 29, we would still have to consider the loads in the neighboring moments of time because they influence the necessary size of the plant on account of the overload capacity of the equipment.[2]

33. For these two reasons we have to extend the theoretical moment at which the peak-load responsibility takes place over a certain length of time, 2 minutes, or 10 minutes, or 30 minutes, etc. Just how long this period should be chosen depends on the shape of the highest portion of the load curve of the central station (short and steep or round and flat). This taking into account of the "near-peak load" is at the same time an approach to the fulfillment of the postulates of the exact theory as set forth in Insert VI. (Compare also Sections 28 and 29.)

34. During the assumed duration of the central station's peak load the load on the central station will be practically constant. But the load of the respective individual consumer or group of consumers during that interval may vary within wide limits, in fact from 0 to 100%. The question arises, then, which one of the loads of the consumer is to be taken as peak responsibility. Evidently we have to assume some kind of average of the consumer's loads during the interval.

35. If the central station's equipment would not have any time element involved in its overload capacity we might simply take the arithmetical average of the consumer's loads, that is, the number of kilowatt-hours consumed by him during the central station's peak-load interval, divided by the duration of that interval (in hours, or fractions of an hour).

36. But as stated above, the overload capacity of a large portion of the equipment (generators, transformers, cables and other electrical apparatus) depends on the temperature rise of the equipment,

[1]As the peak responsibility is generally not made the basis for the demand cost in practice, the principles deduced in this and the following sections are not practically applicable to the peak responsibility, but they are reflected in the practical methods of determining the basis for the consumers' demand cost (maximum demand, see later Section 38 et seq.).

[2]The load which electrical machinery, cables and other apparatus is able to carry is in general determined by the temperature rise, that is, by the heating effect of the current being generated in, or passing through, the respective equipment. We can therefore put a heavier load than normal (24-hour load or "continuous rating") on electrical equipment without doing any damage, provided that the overload does not last longer than until the maximum permissible temperature is reached. The heavier the overload, the shorter is the period during which it may be applied without damage. For instance, electrical machinery will generally be able to carry a momentary overload of 50% of the continuous rating, but it will stand only about 125% of the continuous rating for half an hour without overheating. Now, it is clear that if we have loaded the equipment, for instance for 29 minutes, with 125% it will no longer be able to safely withstand immediately afterwards an overload of, let us say, 15% as long as it would otherwise.

that is, on the combination of the heating effect of the current passing through, or generated in, the equipment and the cooling effect of convection, radiation, etc. This fact suggests the choice of another average for the value of the consumer's peak responsibility such as would be furnished by the readings of an instrument constructed to register the maximum temperature rise of an element which is heated by a conductor connected in series with the consumer's load. (Wright demand meter, see later Insert XVI.) The instrument would thus reproduce to a certain degree the heating effect developed in the electrical machinery.

It must not be left out of consideration, however, that the heating and cooling effect of such an instrument may be—and generally is—different from the corresponding effect on the electrical machinery, not only in size but also in its variation with time, although they follow similar laws.[3] Also the heating curves of the various parts of the electrical equipment are different from one another.

The question which one of the two averages to choose is further complicated by the fact that the temperature rise determines the overload capacity for a certain portion only of the central station's equipment, whereas the permissible overload of other parts of the equipment is determined by other factors without any time elements entering.[4]

37. Neither of the two averages will, therefore, give an entirely correct solution and we can hardly say that one solution comes much nearer the theoretically true value than the other. We have, moreover, moved so far from the exact theoretical conditions of the problem by the previous simplifying assumptions[5] that these nicer distinctions and details of the influence of the duration of the loads and overloads on the demand cost are entirely obliterated and swallowed in the inaccuracy introduced by these approximations. For all these reasons we cannot say that we ought to give the preference to either method of averaging the instantaneous demands during the peak-load period.

4. The Consumer's Maximum Demand and Substitutes Therefor.

38. Even allowing all the approximations for the computation of the consumer's demand cost which have been made so far (see footnote[5] to preceding section), conditions would still be too complicated for practical application to the individual consumers, except to those of the very largest size. In order to compute the demand cost of every consumer on the basis of his peak responsibility it would be necessary to know every consumer's peak responsibility. We would have to place a curve-drawing wattmeter or ammeter (which are very expensive instruments) on every consumer's premises. At the end of the year we would have to find out from a similar instrument in the central station just at what date and what hour the peak load of the central station has occurred and then determine from every individual consumer's chart how large his average peak responsibility has been during the period of the central station's peak load. All this is obviously a commercial impossibility, on account of the high cost not only of the necessary instruments but also of the handling of their record charts. For this reason we have to apply a further approximation to determine the consumer's share of the demand cost, as follows.

39. We do not determine the consumer's kilowatt demand at the time of the central station's peak load, but rather his demand at the time of his own peak load, that is, his "maximum demand" in kilowatts (or watts) regardless of the time when it occurs, the assumption being that the consumer's maximum demand is proportional to his peak responsibility. This is rather a bold assumption, inasmuch as it seems to amount to nothing less than that the shapes of all the load curves of all the consumers are similar amongst each other and thereby also to the central station's load curve. But, as will be shown later (Section 42), the error introduced by this assumption can be materially reduced by classifying the consumers into groups of such character that the curves of all customers within each group are liable to be similar to each other (compare also Section 9); the choice of the consumer's maximum demand instead of his peak responsibility becomes then entirely justifiable.

40. A consumer's maximum demand is much more easily and cheaply determined than his peak responsibility. We can use comparatively inexpensive instruments for that purpose, the so-called maximum-demand meters or demand indicators. These instruments indicate only the maximum demand during any chosen period, just as a maximum thermometer records the maximum temperature during any chosen period. And just as a maximum thermometer is very much cheaper than a curve-drawing thermometer, so a maximum-demand indicator is much cheaper than a curve-drawing wattmeter, not to speak of the cost of the handling of the charts.

Or we can use another type of instrument, the so-called demand limiter, which automatically limits the amount of the maximum demand of the consumer by interrupting his current and making his lights flicker as soon as he exceeds the given amount of demand. He can, therefore, never cause a greater demand cost than the adjustment of the instrument will permit.

With a corresponding sacrifice of accuracy we can even go so far as to abandon all such instruments. We can simply estimate the maximum demand to be expected from the size and character of the installation. This will be discussed more fully when we come to the systems of charging, that is of making the rates or prices (Part II of this series of articles).

41. It has been shown above that where the consumer's peak responsibility is made the basis of the demand cost we have to take the consumer's demands over a certain period of time and then take an average of all these instantaneous demands. Similarly, we have in this case also to take not the instantaneous demand of a given moment but the average of all the instantaneous demands during a certain period of time when the demands are at and near their maximum, including the elements of time shortly before and after the real maximum demand occurs. The average may again be the arithmetical mean or the heating equivalent, as has been explained in Section 36. The instruments employed to determine this maximum demand will be described later in Insert XVI.

[3] See "Rates and Rate Making," P. M. Lincoln, Transactions A. I. E. E., 1915, page 2279.

[4] Thus the boilers and prime movers (this term means the non-electrical machinery driving the dynamos) respond to overloads by a reduction in efficiency and an increase of wear and tear; the distribution lines do not allow of any overload at all, as this would result in an excessive drop of voltage which should be avoided even for the shortest period of time.

[5] Mentioned in the second footnote of Section 17; also, the further assumption that the demand cost is proportional to the peak responsibility is an approximation. In addition to these the assumption to be made later for practical application that the consumer's maximum demand is proportional to his peak responsibility.

Insert VI—Appendix to Section 28—Continued.

1. Curve "h."

Given curve "*B*," that is, the load curve of the central station, it must be transformed in such a way that the ordinates are arranged from left to right in the order of their lengths, to get the curve "*h*."

The construction of this curve is as follows (see Fig. I[1]). We have to cut up, as it were, the whole area under the curve *B* into vertical strips of very small (infinitesimal) width *dt* and then rearrange these strips in the order of their magnitude from left to right. One of these strips is shown shaded in Fig. I.

From the highest maximum of *B*, that is from the point B_{m1}, a horizontal line is drawn towards the axis of ordinates; it intersects the latter at the point *H*. This point evidently is the starting point of the *h*-curve. Considering now some other ordinate h_1, there will generally exist at least two points u_1 and u_2 on curve *B* which correspond to this ordinate. If now we select all those of the above-mentioned vertical strips which are higher than h_1, in order words, which correspond to ordinates larger than h_1, and arrange them side by side beginning from the axis of ordinates in order of their magnitude, these strips will take up a space of the width $= u_1u_2$. The curve *h* will therefore contain a point with the ordinate h_1 and the abscissa $u_0U = u_1u_2$. In the same manner any number of points of the curve *h* can be found. If the respective parallel to the axis of the abscissae intersects the load curve of the central station in more than two points—for instance, in v_1, v_2, v_3, v_4, then v_0V must of course be made equal to the sum of $v_1v_2 + v_3v_4$. It will be noticed that the *h*-curve has several breaks, at W_1, W_2 and W_3. Every maximum (other than the peak load B_{m1}) and every minimum of the *B*-curve causes such a break, as is easily understood from the construction of the *h*-curve. Usually the *B*-curve extends over a complete cycle, which means the end ordinate (point B_z) has the same height as the initial ordinate (point *B*). If this is not the case, as has been assumed for the sake of getting a general case in Fig. I, the end ordinate at B_z or the initial ordinate at *B*, both, will also cause such a break.

In Fig. H, which starts from an assumed *h*-curve, this curve is so chosen that it does not contain any such breaks, but the method of the subsequent construction is exactly the same where such breaks occur. (Also see Fig. L.)

2. Curve "a."

According to the definition (see Fig. F) *a* is the instantaneous demand of the respective customer at the moment when the total demand on the central station equals *h*. Fig. I shows, however, that usually there is more than one value of instantaneous demand of the customer corresponding to a certain given amount of load of the central station, since that given amount of central-station load will generally occur more often than once. Thus, for instance, in Fig I when constructing the point *U* of the *h*-curve which has the ordinate h_1 we found that there are two points in the central station's load curve *B* which have that same ordinate h_1; consequently, there will be also two ordinates (generally of different lengths) of the customer's load curve *b* corresponding to that ordinate h_1 of the *h*-curve. They are r'_1r_1 and r'_2r_2. The question arises which one of these two ordinates should be chosen. Resuming the above-mentioned method of cutting up the area into vertical differential strips it is clear that the strip attributed to point *U* actually is composed of two parallel strips side by side, each one having a width *dt*/2, one of which owes its existence to r'_1u_1, the other one to r'_2u_2. It is evident from this that the ordinates of the *a*-curve must be equal to the arithmetical mean of the different ordinates of *b* belonging to the respective point of the curve *h*.

Thus $U'a_u = (r'_1r_1 + r'_2r_2)/2$.

Every one of the breaks of the *h*-curve mentioned above (W_1, W_2, and W_3 in Fig. I) is connected with a sudden drop (or rise) in the ordinate of the *a*-curve. Thus, for instance, for the abscissa OW'_1 the *a*-curve takes a sudden jump downwards from a_1 to a_2. The reason for this is that at this abscissa the ordinates of the second peak (B_{m2}) of the *B*-curve enter into the *h*-curve and consequently the ordinate of the *a*-curve is no longer the arithmetical mean of *two* ordinates of the *b*-curve, situated on either side of the peak B_{m1}, but it suddenly becomes the arithmetical mean of *four* ordinates of the *b*-curve, one on either side of B_{m1} and one on either side of B_{m2}.

3. Curve "q."

Whereas the ordinates of the two curves "*h*" and "*a*" dealt with heretofore are given in units of kilowatts, the term of $q = a/h$ is an abstract number and a certain length must be chosen as unity. It has been mentioned before that the maximum demand of the central station (*OH* in Figs. H and I) should be chosen as unity.

The construction of curve $q = a/h$ is obvious and hardly needs any explanation. It is shown in Fig. J for a certain abscissa Op_1. H_1 and A_1 are the points on the curves *h* and *a*, respectively, belonging to the abscissa Op_1. *O'* is chosen somewhere on the axis of abscissae in a convenient position. H'_1 is found as the intersection of the extension of line $O'H_1$ with a horizontal line drawn from the starting point *H* of curve *h* (compare Fig. I). Q'_1 is found as the intersection of $p'_1H'_1$ and $O'A_1$; a horizontal line from Q'_1 furnishes in its intersection with p_1H_1 the required point Q_1 of the curve of *q*.

$$\frac{p'_1Q'_1}{p'_1H'_1} = \frac{p_1A_1}{p_1H_1}$$

and, since $p'_1H'_1 = OH$ has been assumed as unity,

$$p'_1Q'_1 = \frac{p_1A_1}{p_1H_1} = \frac{a}{h} \text{ or } p_1Q_1 = \frac{a}{h} = q.*$$

Where possible, the location of O^1 should be chosen so that $p'_1H'_1$ coincides with the axis of ordinates, which saves a little labor.

Every break in the *h*-curve mentioned above with consequent sudden drop or rise of the *a*-curve corresponds to a sudden drop or rise in the *q*-curve (see Fig. L).

4. Curve "f".

According to the definition, the ordinates of the *f*-curve for a given abscissa *Om'* (see Fig. H) are represented by the

[1]To avoid misunderstandings it should be kept in mind that Fig. I deals with the construction of the *h*-curve and the *a*-curve from a given *B*-curve and *b*-curve, whereas Fig. H deals with the construction of the *q*, *f* and *g*-curves, beginning with an assumed *h*-curve which is not identical with the *h*-curve arrived at in Fig. I. Fig. L (see later), being an example from practice, will then show how the different operations tie together if carried out consistently on the same set of curves.

*An additional feature of the construction of the curve *q* is the following: $q = a/h$, differentiate with respect to the time *t* (the abscissa):

$$\frac{dq}{dt} = \frac{h\frac{da}{dt} - a\frac{dh}{dt}}{h^2}$$

From this we see that q reaches a maximum (or minimum) if:

$$\frac{\frac{dh}{dt}}{\frac{da}{dt}} = \frac{h}{a},$$

in other words, if the tangents of such points of the two curves *h* and *a* as have the same abscissa intersect each other on the axis of abscissa (for instance, abscissae Om_1 or Om_2 in Fig. H). By means of this principle it is easy to predict with a fair amount of precision the position of the maxima and minima of the curve *q*.

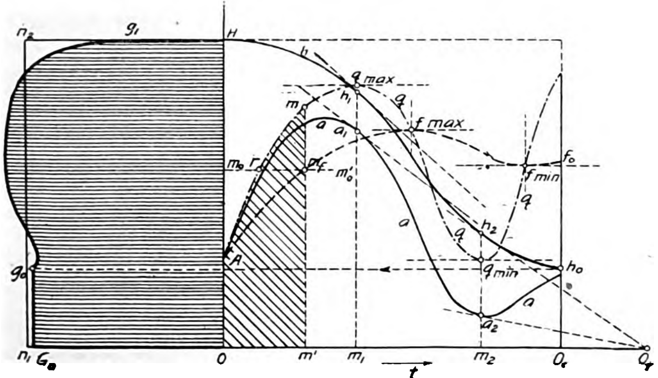

Fig. H.

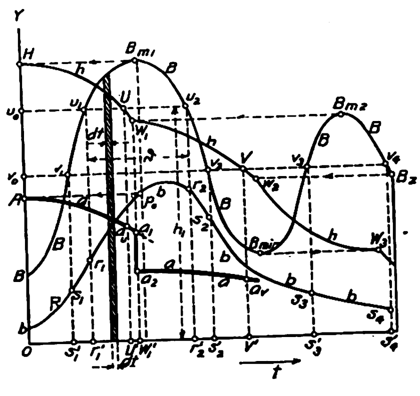

Fig. I.

height of a rectangle erected over the base Om' and enclosing the same area as the surface enclosed by the curve q, the ordinate over the point m' and the two axes of co-ordinates. This last named area is shown shaded diagonally. If we desire therefore to find that point m_f of curve f which belongs to a certain abscissa Om' we have to select a horizontal line $m_0m'_0$ at such a height that the two three-cornered figures Am_0r and mm_fr have the same area. The use of a planimeter will generally not be necessary and a person with fairly good

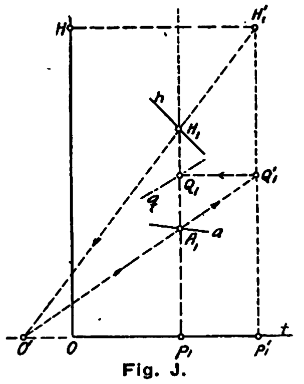

Fig. J.

eye-measure will be able to locate these horizontal lines accurately enough by the eye.

A few additional characteristics as explained hereafter of the curve of f will facilitate an exact and rapid construction of that curve.

Maxima and Minima.—Since the ordinate of every point of f is the arithmetical mean of all preceding ordinates of the curve q, it is evident that f will have either a maximum or a minimum every time it intersects curve q. Thus, for instance, in the left part of the f-curve in Fig. H the ordinates of q are larger throughout than those of f, therefore with increasing abscissae the arithmetical mean of the ordinates of q will grow, that is, curve f will rise. As soon as q falls below f, that is, to the right of the intersection point f_{max} of the two curves, every addition of a new ordinate of q will decrease the average and f will assume a falling tendency until the next intersection point f_{min} is reached, etc.

Direction of tangents of curves.—Expressing the definition of f mathematically we get

$$f=\frac{\int_0^t qdt}{t}$$

where f is the ordinate of the curve of the same name and t is the abscissa. From this we get $ft=\int_0^t qdt$ and differentiating

$$fdt + tdf = qdt$$

$$\text{or } \frac{df}{dt}=\frac{q-f}{t} \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

this means with reference to Fig. K that $t_fm_ft_f$ (the tangent to the curve of f) is parallel to m_0mt_0 where m_0 is again (as in Fig. H) the horizontal projection on the axis of ordinates of the selected point m_f and m is the point on curve q with the same abscissa as m_f; we thus get easily and quickly the direction of the tangent of every point of curve f. From the definition of f it follows that the curve of f will start from the same point A of the axis of ordinates as the curve of q. (Figs. G, H and K.) For this point A ($t=0$, $q=f$) equation (2) changes into

$$\frac{df}{dt}=\frac{0}{0}=\frac{dq}{dt}-\frac{df}{dt} \quad\ldots\ldots\ldots\ldots\ldots\ldots (2^*)$$

Now $\left(\frac{dq}{dt}\right)_{t=0}=\tan\phi_0$ (see Fig. K) and $\left(\frac{df}{dt}\right)_{t=0}=\tan\psi_0$.

Substituting this in equation (2*)

$$\tan\psi_0 = \tan\phi_0 - \tan\psi_0$$

$$\tan\psi_0 = 1/2 \tan\phi_0.$$

This equation allows us to rapidly and easily find the angle at which f rises from its starting point A on the axis of ordinates.

Every sudden drop or rise of the q-curve as mentioned before causes a sudden change in the direction of the f-curve, but in practice these changes in direction, especially for large abscissae, will be imperceptible (Fig. L).

5. *Curve "g."*

The construction of the curve of g is so simple that it hardly needs any explanation. Select a point on curve h (Fig. H), draw a horizontal line from the same to the left beyond the axis of ordinates and on that line from its intersection with the axis of ordinates step off that ordinate of the f-curve which belongs to the same abscissa as the originally selected point of h. Repeating this for a number of points we arrive at the curve of "g."

After we have thus reached, from left to right, the point which corresponds to the lowest value O_0h_0 of the h-curve (at the extreme right of the latter) the ordinates of the g-curve are constant and equal to the terminating value O_0f_0 of the f-curve. The g-curve, beginning from the point T_0, will therefore change into a straight line parallel to the axis of abscissae OH of the g-curve, that is, to the axis of ordinates of the rest of the curves. (That this must be so is easily understod if we go back to Fig. G.)

Summary.

This whole procedure of establishing the equivalent demand is not a very simple one, but it is more simple than it appears at first sight. It must also be considered that the problem itself, as has been shown above, is an inherently intricate one and involves a great many factors.

We see that the consumer's demand cost is an intricate function of the *entire* load curve of the central station *and* of the *entire* load curve of the respective consumer, not only of certain parts of those curves. The equivalent demand and consequently the demand cost, is represented by the shaded area of curve "g," Fig. H, and instead of being simply proportional to the peak responsibility it is a true integral extending over all elements of time over which the load curves extend[2]. As will be demonstrated in the following, however, at those times when the central station's load is low the influence of the consumer's load is small and ultimately even becomes practically negligible compared with the influence of the consumer's load at or near the central station's peak load time. Yet all these infinitesimal influences of the various differentials of time are of the same *order* of magnitude.

It is obvious that the f-curve (which represents by its ordinates the respective areas under the q-curve) has the tendency of approaching more and more a horizontal straight line as the abscissa increases, that is, as the instantaneous load h of the central station decreases. (Supposing, for instance, that the f-curve stands at $0.1 \times OH = 0.1$† at the end of the first hour and that $q=0.3$ throughout the following hour; then at the end of that hour, f will have risen to $(0.1+0.3)/2=0.2$, or by 0.1, or by 100%. If, however, the f-curve stands at 0.1 as above, not at the end of the first hour but at the end of the 23rd hour, and q is again $=0.3$ throughout the following hour, then at the end of that hour f will be only $(23 \times 0.1 + 0.3)/24 = 0.1125$, or it will have risen only by 0.0125, or by 12.5%.)

This means that the values of the consumer's load for small central-station loads (large abscissae of h-curve),

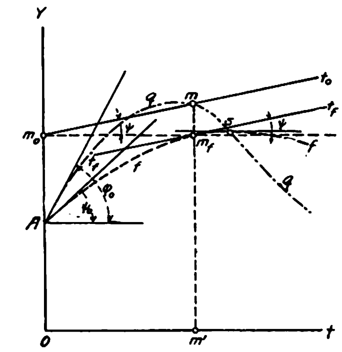

Fig. K.

where the f-curve is already steadied, will not be able to affect the equivalent demand and the demand charges as much as the consumer's load at those particles of time, when the central station's load is near its peak. The consumer's loads near the central station's peak load have a greater influence than where the central station's load is small, so much so that in the generality of cases at all moments when the central station's load is not near peak load the amount of the consumer's load need not be considered. Nevertheless, as will be shown by an example from practice a little later (Fig. L), *the equivalent demand may be very far off from the peak responsibility.*

Theoretically the load curve would have to be taken over

[2] This integral is, of course, not identical with the integral which gives the energy consumed $\int_0^t b\, dt$ (Fig. I) and it is of a much more complex nature. Further investigations (which are omitted here) show that it is a double integral.

†It should be remembered that OH has been chosen as unity.

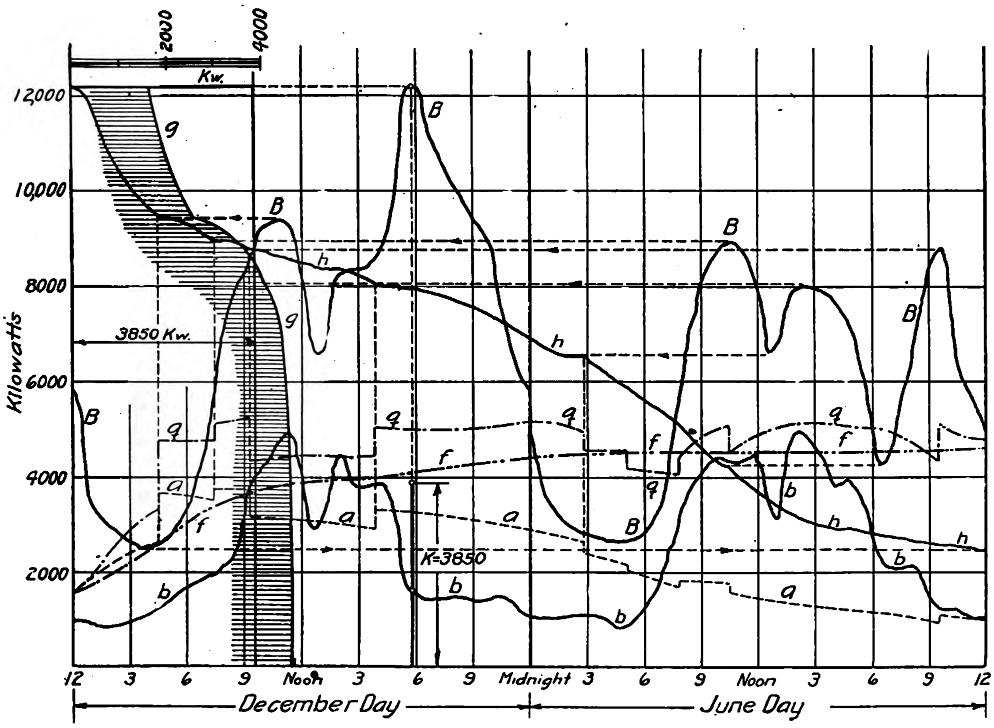

Fig. L.

the whole year. But in practice this is neither possible nor necessary. In ordinary cases it will be sufficient to take one typical day around the winter and one around the summer solstice.

Fig. L is an example from practice showing the curves of a large central station which was the first one to employ this method devised by the author. The diagram has the purpose of determining how the aggregate peak load for light and power should be apportioned between the power consumers and the lighting consumers, in other words, how large the aggregate equivalent demand of each one of these two groups is. Fig. L shows the total lighting and power curve B and the power load curve alone b. A December day and a June day were selected as representative of the extreme seasons of the year. We see plainly how every peak and every valley of the B-curve causes a break in the direction of the h-curve, as explained before, and a sudden jump up or down in the q-curve. The resulting breaks in the direction of the f-curve are so small that they are hardly discernible in the left-hand part of the curve and disappear entirely to the eye after the first quarter of the total abscissa. We see from this practical example also how the f-curve as well as the g-curve[3] become practically level, beginning about the second half of the respective total abscissa.

The peak load of the central station occurs shortly before 6 p. m. in December and amounts to about 12,200 kw.; the peak responsibility of the power load is only about 1600 kw. The equivalent demand, however, in consequence of the great power demand at other hours is not less than 3850 kw. or nearly 2½ times as high as the peak responsibility. The balance of 12,200 — 3850 = 8350 kw. is charged to lighting.

Note.[4]

A glance at Figs. A(a) to A(g) shows that in each case customer B has used 600 kw. continuously during the hours between 2 o'clock and 6 o'clock. If the equivalent demand for B is figured by the same method as given above (see page 185) but on the basis of Figs. A(a) to A(d), the results will be the same as before in Fig. A. On Fig. A(e), however, we get the following result from the equivalent demands:

Customer A.... $\frac{1}{3} \times 400 + \frac{1}{5} \times 200 + \frac{1}{3} \times 400 = 306\frac{2}{3}$ kw.
Customer B.... $\frac{2}{3} \times 400 + \frac{4}{5} \times 200 + \frac{2}{3} \times 400 = 693\frac{1}{3}$ kw.

1000 kw

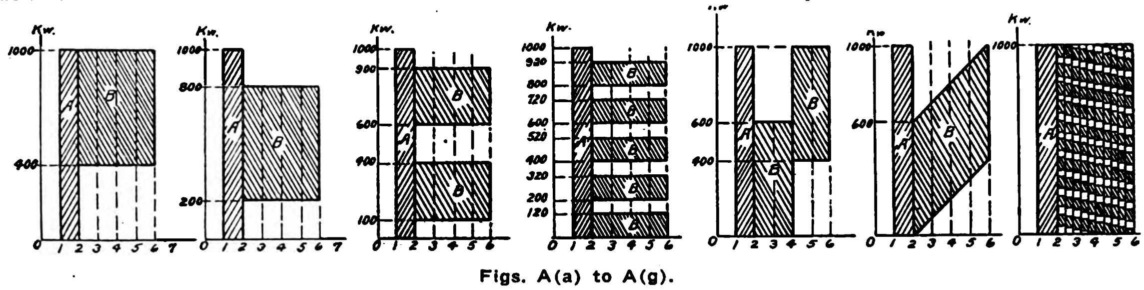
This is very different from the result given on the basis of Fig. A or Figs. A(a) to A(d). If A and B were to deal directly and independently with each other about the use of the central station (for instance, in case they are joint owners of the central station) A might contend that the distribution of the demand charges should be made according to Fig. A(e), whereas B would probably claim that the load curves should be drawn as in Fig. A and not as in Fig. A(e). Who is right, A or B?

The 1000-kw. central station might be imagined in this case to consist of five units of 200 kw. each (it does not matter for the purposes of this deduction whether these five units are actually in physical existence as such or not). According to Fig. A, customer B would use none but the first three of these units (counting from the bottom up in the drawing). If Fig. A(a) is made the basis of the computation, he would be using only the three uppermost units, etc. In Fig. A(e) customer B would use the three lowest units for the first two hours and the three uppermost units for the last two hours.

Let it now be supposed that this latter assumption [Fig. A(e)] be permissible; then evidently there is no reason why the total time between 2 and 6 o'clock should be divided into only two periods of that kind. With the same right, four subdivisions of time might be assumed, of one hour's length each, or eight, etc.; in fact, there is no upper limit to the number of subdivisions of that period. We can, therefore, assume an infinite number of very small periods and suppose that during each one of these periods B is drawing his 600 kw. from another part of the central station. This may

[3]In order to save space in the drawing, the ordinates of the g-curve have been stepped off to the right of the main axis of ordinates instead of to the left as on the other illustrations. The g-curve is emphasized by shading.

[4]Referring to first paragraph in the second column of page 185 of the last issue.



Figs. A(a) to A(g).

result for instance in Fig. A(f). If Fig. A(e) is permissible as a basis of computation, moreover, we are certainly at liberty to assume the subdivision of the demand of *B* also in the manner indicated in Figs. A(c) and A(d). This subdivision in vertical direction can also be carried out to finer and finer degrees, and can be combined with the manner of subdivisions shown in Figs. A(e) and A(f); this will result in a distribution of the demand about as shown in Fig. A(g). If these combined subdivisions are carried out to sizes of infinitesimal order this obviously means that the demand charge be distributed proportionately to the number of kw.-hr. used, independently of the shape of the load curve. This evidently is absurd; therefore, the basic assumption of the whole conclusion must be wrong. This initial assumption has been that the distribution according to Fig. A(e) is permissible and we arrive, therefore, at the conclusion that the distribution according to Fig. A(e) is wrong. With two customers only the distributions of the load curve of the type of Figs. A, A(a) to A(d) are the only ones which are correct, but not A(e) and A(f), and it is easy to see that they all have the same result as to the equivalent demand charge. An analogous deduction shows that with three or more customers the load curve of every single customer must be drawn in the customary way in order to obtain correct results; that is, with the axis of abscissae as a basis from which to step off all ordinates of every single load curve, as in Fig. A.

(To be continued.)

FISCAL YEAR'S FOREIGN TRADE EXCEEDS TEN BILLION DOLLARS.

All Records Broken as to Exports and Imports—Excess of Former in Last Five Years Exceeds That of the Preceding 125 Years.

An excellent indication of the growth of American business in the last few years is given in the following figures on our extraordinary foreign commerce of the last fiscal year.

United States commerce in the fiscal year which ended June 30 broke the record in many particulars. Both imports and exports were the largest in the history of our foreign trade, and the grand total for the first time crossed the $10,000,000,000 line; the "favorable trade balance" exceeded that of any earlier year, and the closing month, June, wound up the spectacular record with a total trade of $1,211,282,450, an average of nearly $50,000,000 a day in the 26 business days of the month. The value of the merchandise forming the foreign commerce of the United States in the fiscal year 1919 was one-half as large as that forming the entire international trade of the world in the year preceding the war.

The exact record of this remarkable year in our trade was, according to a statement by the National City bank of New York: Imports, $3,096,000,000, against the former high record of $2,945,655,000 in 1918; exports, $7,226,320,000, against the former high record of $6,290,048,000 in 1917; the grand total, $10,322,460,000, against the former high record of $8,949,404,000 in 1917. The excess of exports over imports or "favorable trade balance," was $4,129,000,000, against $3,630,639,000 in the former high record year of 1917. The favorable trade balance in the five years since the beginning of the war is greater than in the 125 years preceding the war. The gold imports in the last five years aggregated $1,823,000,000, and the gold exports $785,000,000, making the net importation of gold in the five years $1,038,000,000. The excess of exports of merchandise in the same five-year period was $13,963,000,000, this difference between net exports of merchandise and net imports of gold being largely offset by the Government's credits of $10,000,000,000 to our European allies.

LARGE PORTION OF CITIZENS INTERESTED IN UTILITIES.

Recent Statement Shows One-third of Illinois People Financially Affected by Utilities.

At a recent meeting of utility managers and operators held in Springfield, Ill., to lay plans for a closer co-ordination of effort in placing the after-the-war problems of utilities before the public the statement was made that 33⅓% of all citizens of Illinois, directly or indirectly have a financial interest in the public utilities of the state. The conference was held under the auspices of the Illinois Committee on Public Utility Information which has been created by the various associations of the combined utility industry of the state.

Speakers at the meeting declared that the ramifications of the industry are such that fully one-third of all citizens now have a financial interest, either as wage earners, security holders or through collateral industries dependent upon the utilities. Of the total of all citizens of the state, 193,700 are directly in the employ of the electric, gas, telephone, water, street and interurban railways or railroads and 153,600 others are employed in industries dependent upon the public utilities. These 347,300 wage earners, with their families, represent 1,736,500 persons dependent for their living upon the industry, or 17% of the entire population. In addition there are 230,000 security holders, who with their families total 1,150,000 persons, who are indirectly affected.

INVENTION CLAIMED TO INCREASE CONDUCTIVITY OF ALUMINUM.

Electrical men will be interested in the following submitted by United States Consul Philip Holland, of Basel, Switzerland, and published in *Commerce Reports* for Aug. 2:

"A new invention called conducting aluminum M. 277, which is said to be creating a profound impression, has been made by Dr. Georges Giulini, the most famous expert in the aluminum trade. This new metal is produced by putting the ordinary aluminum through a special patented process, by which it acquires the same mechanical qualities and capacities as bronze, copper, and brass without changing its specific weight.

"It is said that the price of the new metal can be kept within very low limits; so that, even at the prewar prices of other metals, it will be able, by reason of its smaller specific weight, to compete with copper and brass very favorably. The fact that the new metal is a conductor will make it especially in demand in the electrical trade. The inventor anticipates also a good market for it among the builders of motor cars, aeroplanes, ships, and railway carriages. Leading men, to whom the invention is already known, are said to be much impressed with its possibilities."

ELECTRIC UTILITIES IN JAPAN INCREASING.

It is stated that there are 715 electrical utility undertakings in Japan, including 625 power plants, 42 electric railways, and 48 companies operating both power plants and tramways. This is an increase of 40 companies over last year and evidences the growing popularity of electricity in that country.

Wireless Telephone Transmitter for Seaplanes

Light-Weight but Powerful Set Developed for Use by Navy's Flying Boats During the War

MARKED progress in the perfection of airplane wireless telegraph and telephone apparatus is a direct result of exhaustive researches in radio communication which have been conducted during the past two years. Light-weight transmitters having a sending range of 150 miles or more have been developed. Spark apparatus has been employed to a considerable extent in airplane communication, but transmitters utilizing the vacuum-tube oscillator have the advantage of permitting either speech transmission or telegraphic signals by damped or undamped oscillations, at the will of the operator.

Practical wireless telephone apparatus of the vacuum-tube type is disclosed in the following description of the Marconi type S.E. 1100 set—a comparatively high-power bulb transmitter—developed by the Marconi Wireless Telegraph Co. of America.

The set was designed primarily for the large flying boats, the H-16 class, of the United States Navy, and has fully satisfied every test to which it has been put. In one of the earlier tests in flight over Chesapeake Bay, telegraph signals radiated from a trailing antenna on an H-16 boat were heard distinctly in Washington, D. C., over a distance of 120 nautical miles. Subsequent tests with the set used as a wireless telephone permitted the accurate transmission of speech over a distance of 150 miles. The transmitter radiates at two wave lengths, 1600 and 600 meters. For the former wave length a trailing wire antenna of 0.0004 mfd. capacity is employed; for the latter, an emergency aerial of 0.00026 mfd.

The transmitter is supplied with two three-electrode tubes of the pliotron type. One tube is employed as an oscillator for the production of radio-frequency currents and the other as a modulator and amplifier of the voice currents communicated to it by the microphone.

The fundamental circuits of the set are shown in Fig. 1, the actual circuit in Fig. 2, a front view of the transmitter in Fig. 3, a rear view in Fig. 4, another rear view in Fig. 5, and a wiring diagram showing the function of the change-over switches in Fig. 6.

For best understanding of the operation of the apparatus, it should first be appreciated that if grid and plate circuits of a vacuum tube include radio-frequency circuits coupled inductively, conductively or electrostatically, alternating currents of any desired frequency may be generated. This is the first requisite; other problems, such as rapid change of wave length, satisfactory modulation and the elimination of disturbing capacities between circuits, arise in the practical set and are of equal importance. They were satisfactorily solved only after diligent research.

In order to set valve circuits into a state of radio-frequency oscillation, it is necessary that the connections be so made that the grid end of the grid inductance will be alternately negative and positive as the plate end of the plate inductance is positive and negative. When the grid and plate radio-frequency circuits are coupled with the proper phase relation, any variation of voltage in either the grid or plate circuits will cause minute disturbances in the oscillation circuits, setting them into oscillation at whatever frequency they happen to be adjusted to. For example, a slight variation of voltage in the plate circuit by any means whatsoever will cause its resonant circuit to oscillate at radio frequency, and the resultant currents will act upon the grid circuit, setting it into oscillation at the same frequency. The resulting radio-frequency fluctuations of the grid potential will act upon the plate at the right time to keep the plate resonance circuit in a state of oscillation, and this state of affairs will continue so long as the proper supply of voltage and filament current is maintained, but not otherwise.

The tube is able to generate alternating currents because of its amplifying properties. The energy delivered to the grid circuit in accordance with the actions just outlined will gradually increase in value until a maximum is reached, which is the maximum output the valve is capable of delivering, as may be discerned from the well-known characteristic curve.

Referring to Fig. 1, it will be observed that the plate and grid circuits of the tube contain the coils *L-1* and *L-2*, in inductive relation, each connected through the condensers *C-3* and *C-4* to the negative side of the filament. The grid oscillating circuit comprises the coil *L-2*, the condenser *C-2* and a protective condenser *C-4*. The plate oscillating circuit includes the condenser *C-3*, a part of the coil *L-1* and the series condenser *C-5*. The antenna and earth connections tapped off from the coil *L-1* take the place of the con-

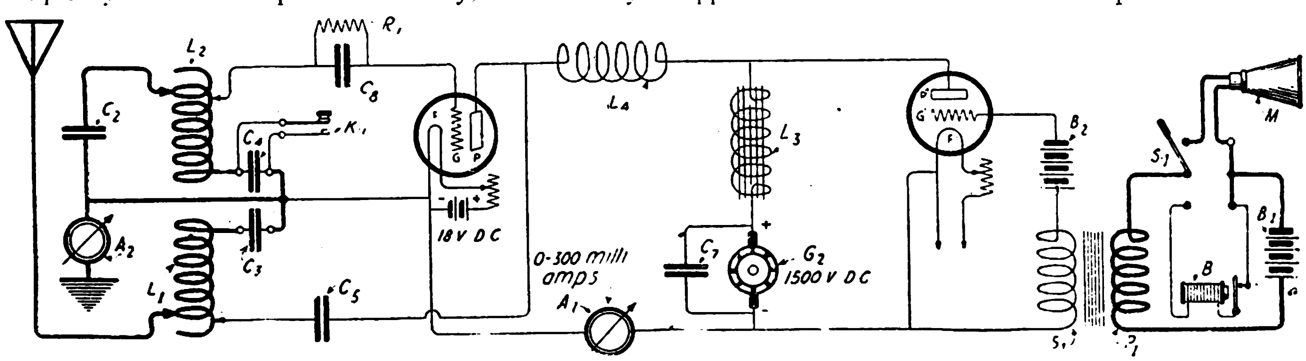


Fig. 1.—Fundamental Circuits of the Wireless Telephone Transmitter for Seaplanes.

denser C-2 in the grid oscillating circuit. C-2 is called the balancing condenser. In series with the grid is another condenser C-8 shunted by a leak resistance R-1, which maintains the grid at a negative potential.

The system further includes a three-electrode tube F', G', P', which amplifies the output of the microphone circuit and simultaneously modulates the output currents of the oscillating bulb.

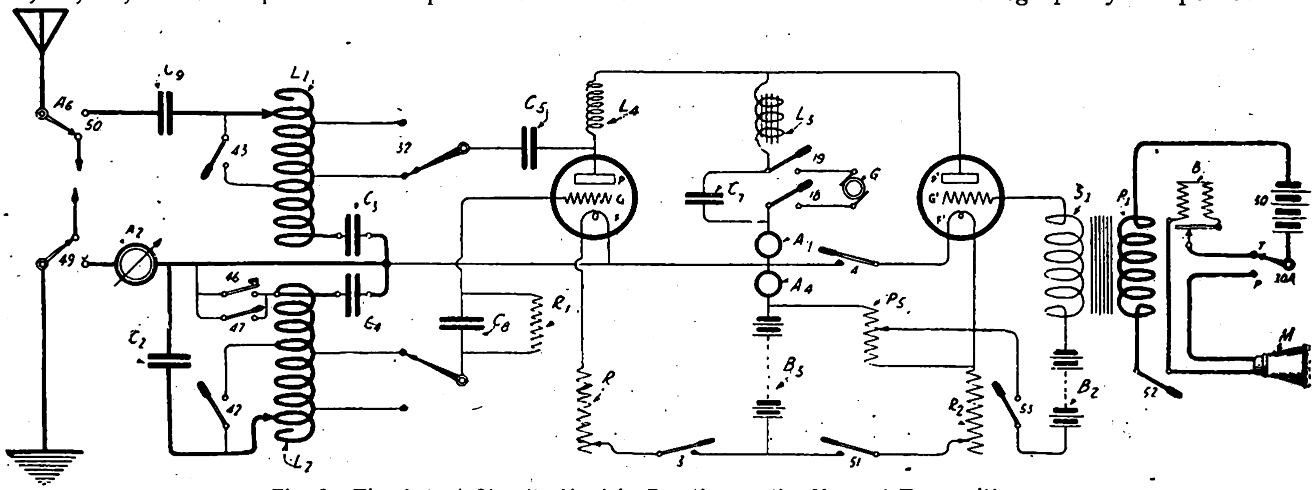

Fig. 2.—The Actual Circuits Used in Practice on the Marconi Transmitter.

It will be noted that the plate circuit is fed by a 1500-volt direct-current generator G-2, the positive terminal of which connects to the plate P of the oscillating tube through the audio-frequency inductance or transformer L-3 and the radio-frequency inductance L-4. The negative side of the generator connects through the milammeter A-1 to the negative side of the filament F. The condenser C-5 is the protective condenser which is generally employed in tube oscillating circuits when the source to the plate circuit is connected in shunt to the plate and to the filament, as is the case in this circuit. The modulating circuit shown to the right of the drawing permits either voice transmission or telegraphy by damped oscillations.

For telephony, the microphone M is placed in series with the telephone induction coil P-1, S-1 and the battery B-1, by means of the switch S-1. The coil S-1 is connected to the grid and filament of the modulating tube and includes in its circuit the battery B-2 through which the grid is held at a suitable negative potential for maximum magnification. The filament and plate of the modulating tube are shunted across the plate circuit of the oscillating tube. The audio-frequency choke coil L-1 may be said to act as a one-to-one transformer. The radio-frequency choke L-4 prevents the radio-frequency currents developed by the oscillator from flowing back to the plate-circuit generator G. C-7 is protective condenser for the plate-circuit generator.

When the transmitter M is spoken into, speech currents of variable frequencies generated by the microphone are impressed upon the grid circuit of the modulating tube and, through the medium of the autotransformer L-3, alternating currents are superposed upon the plate circuit of the oscillator. This in turn varies the amplitude of the oscillator currents at speech frequencies, and accordingly the amplitude of the radio-frequency oscillations flowing in the antenna circuit. It is essential that the key K-1 of Fig. 1 be closed for the production of undamped oscillations, for when it is open the tube stops oscillating. Manipulation of this key permits telegraphic signaling by the undamped oscillations produced by the tube.

When it is desired to telegraph by damped oscillations, the change-over switch S-1 is thrown from the microphone to the buzzer B which is energized by the battery B-1. The interrupted currents fed by the buzzer through the primary P-1 of the induction coil produce alternating currents of higher voltages in the coil S-1, which in turn are magnified by the modulating tube, the latter varying the radio-frequency currents in the oscillator tube at the frequency of the buzzer. In this way, the antenna radiates damped oscillations in groups, the frequency of the groups varying as the number of interruptions of the buzzer.

A more detailed circuit of the Marconi aircraft set appears in Fig. 2. This diagram not only embraces the fundamental connections of Fig. 1, but includes all necessary switches for the three different signaling

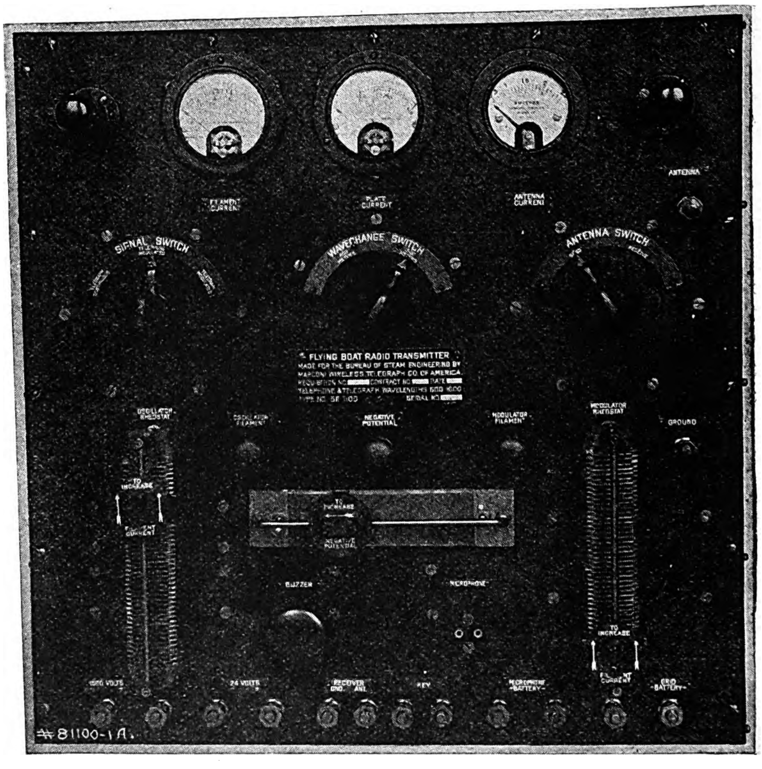

Fig. 3.—Front View of Marconi Wireless Set Used in Seaplanes.

functions on the 600 and 1600-meter wave. It includes, moreover, a detailed wiring diagram of the filament circuits.

The filament circuit divides at the positive terminal of the 24-volt storage battery *B-3*, one branch going through the rheostat *R-1* to the filament *F* of the oscillating valve, and the other going through the rheostat *R-2* to the filament *F'* of the modulating valve. The negative sides of the two filaments are connected together and to ground. In addition there is provided a potentiometer *P-5* connected across the battery *B-3* with a tap leading to the negative potential battery *B-2* and on through the secondary of the microphone transformer *S-1* to the grid *G'*.

The object of the potentiometer in Fig. 2 is to compensate for any loss of negative potential in the grid circuit *G'*, which may be occasioned by the lowering of the voltage of the filament battery *B-1*.

The switches for shifting the connections from one system of signaling to the other are enclosed in drums, as may be noticed in the left-hand part of Fig. 5. The inside and outside rows of jaws on each set are represented by the upper and lower group of dots in Fig. 6. In that figure the left-hand pair constitute the wave-length changing switch, the middle pair the sending and receiving switch and the right-hand pair the signal switch. The first, second and third positions of each switch are indicated by the letters *X*, *Y* and *Z*, these letters being placed between the two points which the blades of the switch short-circuit in that position.

Regarding the action of the oscillating valve itself it should be noted: When the grid is negative in respect to the filament, no current passes between the grid and filament; but when it is positive, considerable current passes which constitutes a loss in the circuit; but if the grid is held at a constant negative potential this energy loss is reduced and a more effective transmitter is obtained. The grid potential may be held at a negative value by the insertion of a grid battery but it can be done in just as effective a way by inserting a condenser in the grid circuit which rectifies the grid currents and holds the grid at a negative potential.

If the leak were not provided, the potential of the grid would rise to such a high negative value that all action would be stopped. A leak of proper value definitely limits the maximum negative potential of the grid and therefore does away with the necessity for a special grid battery.

The numbers on the separate single-pole switches in Fig. 6 correspond with those shown in Fig. 2. The outside row of studs on the wave-length changing switch perform the following functions: In the 600-meter position (*X* at *32* in Fig. 2) the first tap on the upper section of the loading coil *L-1* is connected to the plate series condenser *C-5*, and at *43* short-circuits the end portion of the same coil. In the 1600-meter position *Y*, it connects at *32* the second tap of the coil to the condenser and opens the short-circuit.

The inside row of studs on the wave-length changing switch performs the same functions for the coil *L-2*, which is the lower portion of the long single coil mounted in the middle of the rear of the panel in Fig. 4. In the schematic diagram, Fig. 6, the blade marked *35* is shown connecting to the first tap of the lower portion of the coil in the 600-meter position,

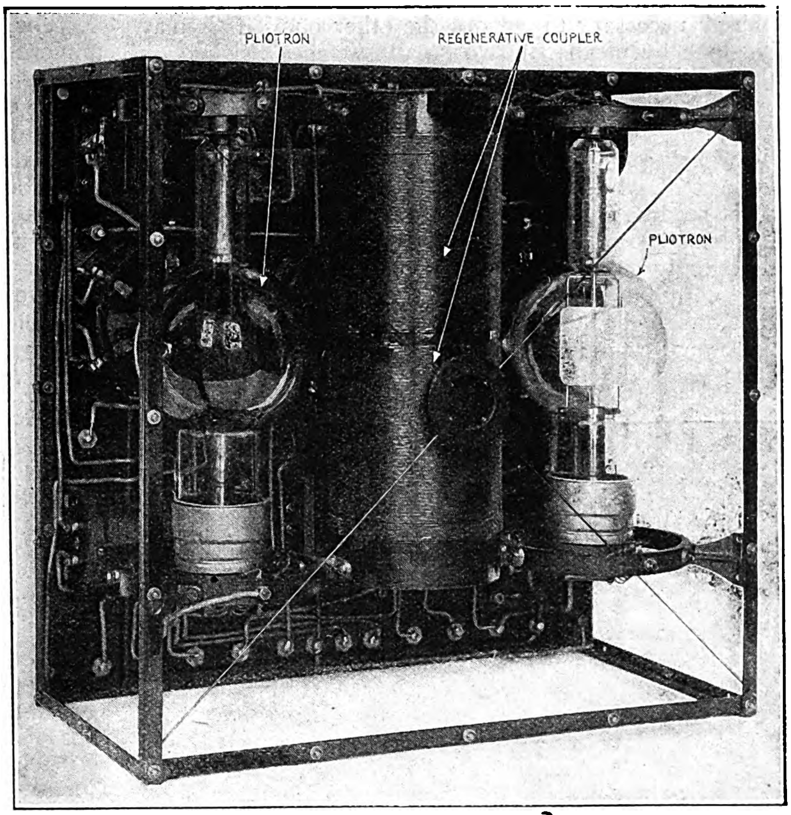

Fig. 4.—Rear View of the Transmitting Set With Pliotrons in Place.

and to the second tap in the 1600-meter position to the grid condenser *C-8* with its leak resistance *R-1*.

The outside portion of the switch marked "send-receive" (in the right-hand position of Fig. 3 and also in the upper central position of Fig. 6) serves to connect the antenna *A-6* to the transmitter in the "send" position (*X*) and to the receiver in the "receive" position (*Y*). In the "send" position the circuit of the antenna at *50* is through the series condenser *C-9* to the top of the loading coil *L-1* and to the ground. The latter is connected at *49* through the antenna ammeter *A-2* to the main ground bus of the set, which is the frame.

The inside portion of the "send-receive" switch, in the lower part of Fig. 6, is idle in the receive position *Y*, but in the "send" position *X* at *21*, it completes the 1500-volt direct-current supply current to the plates *P* and *P-1* of the pliotrons. At *52* it connects the primary of the microphone transformer *P-1* to the microphone terminals *28* and to the buzzer *B*. These connections are opened in the "receive" position.

There are three positions for the signal switch. The first *X* is for continuous wave telegraphy. In this position the connections made in the second and third positions are opened. The second position *Y* is for telephony; the inside portion of the switch (the upper part in Fig. 6) connects the microphone to the microphone battery, and at *51* the outside portion (in the lower part of Fig. 6) completes the filament circuit for the modulating valve and short-circuits the key at *47*. In the third position, the switch connects at *30-A* the buzzer to the microphone battery and at *51* keeps the filament of the modulating valve lighted, removing the short-circuit from the key.

Space and weight considerations demand the fewest possible measuring instruments. A direct-current ammeter *A-4* is connected in series with two filaments and reads the total current taken by both of them. The instrument's scale registers from zero to 10 amperes; to read the current in either filament it is merely necessary to cut out the other one. This may be done by means of two small switches marked on the set "oscillator filament" and "modulator filament."

The principal indicator for checking up the proper operating conditions of the set is the plate current drawn by each of the valves from the dynamotor, the voltage of which, as already mentioned, is 1500 volts. This reading is obtained from the plate-current ammeter *A-1* of Fig. 2, connected in the ground leg of the supply circuit. This instrument reads from zero to 300 milliamperes and measures the total plate current taken by the oscillator and modulator. The maximum voltage developed by the dynamotor is 1600 volts and the vacuum tube generally will cease to operate when it falls below 1100 volts. The generating tube will oscillate over a wide range of plate voltage if the filament current is kept below a certain critical value. The filaments of the pliotrons are designed to operate on 18 volts.

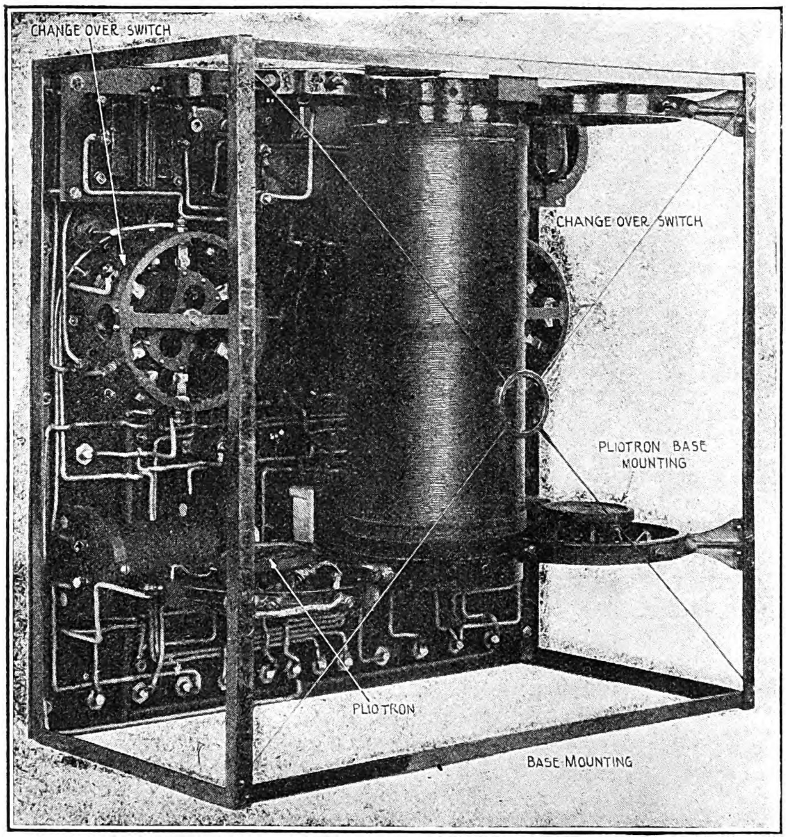

Fig. 5.—Rear View of the Set After Pliotrons Have Been Removed.

The entire set is wired with No. 12 B. & S. gauge bare soft copper wire with empire cloth tubing slipped over it as insulation. No terminal lugs are used; the ends of the wires are bent in the shape of an eye which fits the stud terminal and is passed around it in a direction that tends to make the wire grip the stud when the nut is tightened.

Owing to the vibration of the airplane every possible precaution has been taken to prevent the fastenings working loose. Special steel lock washers are used throughout the set. The general scheme of construction is such that the main supports and fastenings will bend before they break, wood or any material which splits or fractures having been eliminated. The steel wire cross braces shown in the rear views make the structure an extremely light and a surprisingly rigid unit.

The primary source of energy is two 12-volt, 50-ampere-hour storage batteries of the Willard lead type similar to those used in automobile starters. The filaments of the two pliotrons are operated through a rheostat directly from the 24-volt storage battery. Since the tubes require a plate potential of 1500 volts direct current, a small dynamotor, driven by the 24-volt storage battery, is supplied. The armature has two windings in the same slots, one connected to the 24-volt commutator at one end, and the other to the 1500-volt commutator at the opposite end. It is a two-pole machine excited from the 24-volt source. The armature, which runs on ball bearings at 5000 r.p.m. and draws about 30 amperes on its full load at 450 watts, weighs approximately 30 lb.

In addition to the 24-volt storage battery, three other batteries are required; two for the transmitter and one for the receiver. These three sets are known as the microphone battery, grid battery and receiver battery. The voltage of the first is 5; of the second 60, and of the third 40. The 60 and 40-volt sets consist of 20-volt units connected in series.

To insure against breakage, the best position for the pliotrons is vertical with the large neck at the bottom. This brings the plate-terminal cap at the top and the filament and grid-terminal cap at the bottom. In each of the two Dilecto rings shown at the top of Fig. 4, three spiral springs placed 120° apart support a spring cap which fits over the plate-terminal cap of the pliotrons. The springs are held by small machine screws which pass through the insulating ring. One of these serves as a terminal, being connected by a pigtail to the spring tap. In each of the two bottom Dilecto rings, three spiral springs placed 120° apart, support a special jack block made to take the filament and grid terminals. This block is made in two halves, upper and lower, held together by screws; clamping these spring jacks between them, three posts, which project from the bottom of the jack block, take the ends of the three supporting springs and are electrically connected by a copper pigtail to the screweyes that hold the other end of the spring to the Dilecto ring. The two filament terminals of the tube and the grid terminal are brought out to the three screws in the Dilecto ring. Thus, each pliotron is supported to the rigid frame of the set by six springs which are set so that when the tube is in place the top springs pull down and the bottom springs pull up.

The mechanical period of vibration of the vacuum tubes in this spring mounting is considerably below that of any vibration that will occur in the seaplane itself. Sudden shocks in any but a horizontal direction are not transmitted through these springs with sufficient violence to injure the tubes.

The antenna reel group for this set consists of the reel mechanism, a removable drum with antenna wire and spare drums with complete antennae on them. The wire from the reel runs through a take-off pulley and passes through the lead-in insulator in the side of the hull of the boat. It then passes through either a strut pulley or wing pulley, depending upon the type of the boat.

A cast aluminum plate, clamped to one of the main struts in the hull of the boat, carries a shaft on which the drum turns. On this same shaft, next to the attachment plate, there is a brake drum of cast aluminum and around this drum a cast-iron brake band. The band is sprung over the drum and prevents it from turning except when a cam which is attached to the brake lever springs it open. A pin on the brake drum engages holes in the main drum, when the latter is put on the shaft. The crank by which the main drum is turned has a square hub on which the drum sets. It is slipped onto the shaft and latches in place. The latch is released by a latch handle just behind the arm of the crank. To remove the drum, to put a new one in place, the operator grasps the arm of the crank, and in so doing also grasps the latch handle and releases the latch. He then pulls the crank and drum off together. One drum may then be slipped off the hub of the crank and a new one put on, and the two slipped back onto the shaft.

The drum is a pressed-steel spool, black japanned, and will hold about 600 ft. of the standard antenna wire. It has a square hole at its center which fits the hub of the crank. The antenna wire has a ball at the reel end and this ball is dropped through a hole in the drum face. The other end of the wire is attached to a swivel, and this in turn is attached to the "fish" or weight.

The lead-in insulator is a molded Electrose fitting, with a metal tube running through it, and a wide flare at either end, so that the wire cannot catch on the ends of the tube even if it enters at right angles. The insulator is held by locknuts in a hole in the side of the hull. The antenna connection from the set is brought to this insulator. When the antenna is out, the ball on the reel end of the wire rests against the inside flare of the insulator. The wire is thus entirely disconnected from the reel, and the reel is dead. When it becomes necessary to reel up, the ball is grasped and of course brings the wire with it. The ball is passed through the take-off pulley and dropped through the hole in the drum face, and the crank is turned. The brake mechanism is arranged so that the cam may be left holding the brake off during the reeling-up process.

The maximum antenna current is 2.5 amperes, with the antenna supplied with the set. This has been found to satisfy all ordinary distance requirements.

Comprehensive instructions are supplied with each set, enabling the operator to obtain the best adjustment for the three signaling positions with the greatest ease.

SQUARE DEAL TO UTILITIES, THEIR EMPLOYES AND PUBLIC.

In a recent interview on high prices and the general business outlook, Britton I. Budd, president of the Metropolitan Elevated Railway Co. and head of the Chicago Elevated Railways, said:

"We hear a good deal of talk about prices again becoming 'normal' Such talk results from a lack of understanding of what constitutes a 'normal' price of a commodity or a 'normal' wage of labor. If by 'normal' is meant the prices and wages of, say, 1914, I do not believe we shall ever again see such prices and wages, and we should at once begin squarely to face the facts. In my judgment the tendency is toward higher prices and wages.

"As I view it, a 'normal' price is a price based upon the cost of production, so that what was a fair price for a commodity in 1914 is not a fair price in 1919. The same is true of wages for 'normal' wages in 1919 must be based upon what it costs the worker to live according to American standards and allow a reasonable margin for the inevitable rainy day.

"We are entering upon a new era. The future must bring a square deal for labor, a square deal for the public and a square deal for the public service companies, which are now being starved to death for lack of nourishment."

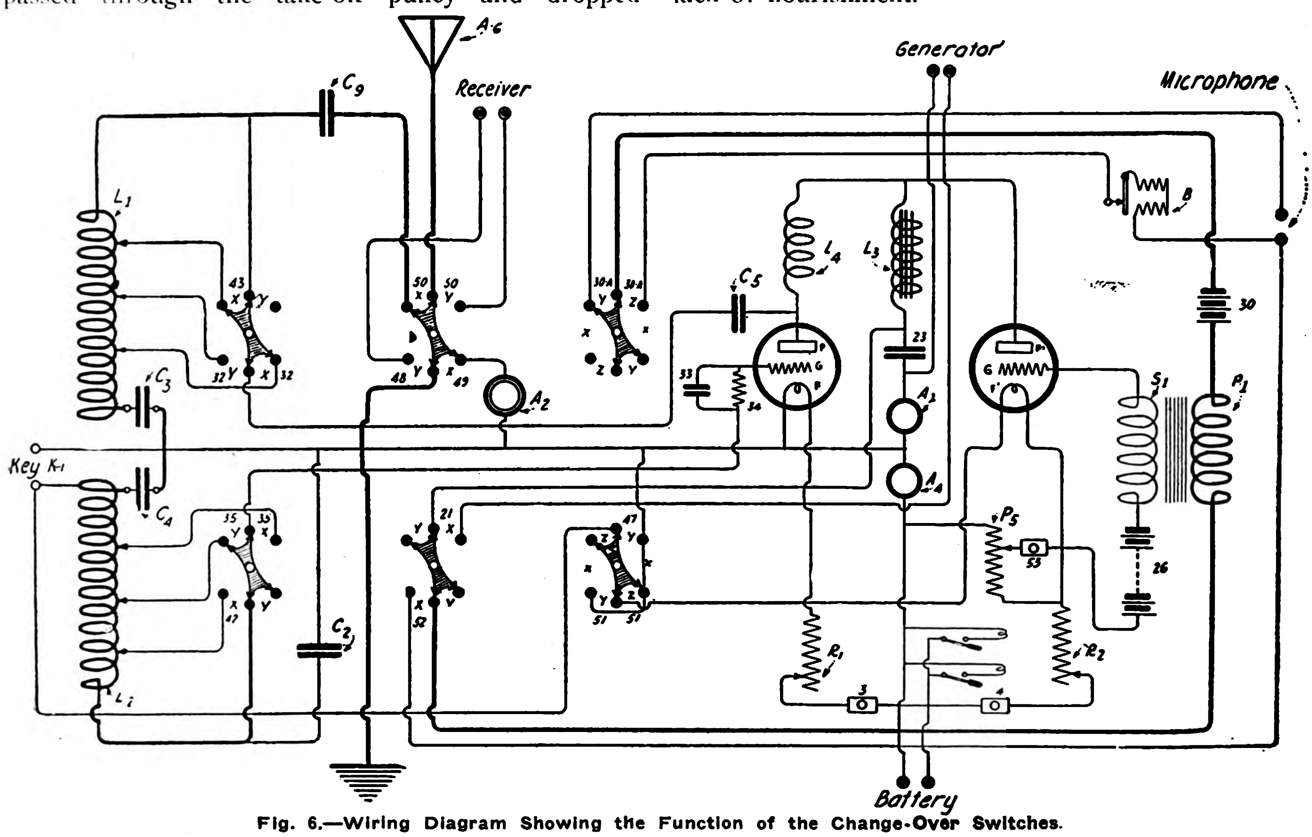

Fig. 6.—Wiring Diagram Showing the Function of the Change-Over Switches.

Editorial Comment

Another Step in Co-operation

ANOTHER big improvement in the conditions in the electrical industry was made recently when the manufacturers of outlet boxes, covers and similar supplies adopted a standard system of numbering their products for catalog purposes. In doing this these companies have evidenced their progressiveness and willingness to co-operate with the rest of the industry and it therefore behooves all others interested in these fittings to familiarize themselves with the new numbers as quickly as possible and use them exclusively when ordering or referring to them. There is no doubt but that the proper use of the new numbers will effect a considerable saving and be much more convenient to all concerned and at the same time enable architects and others not connected with the electrical industry directly to become more familiar with such fittings and their uses.

The most striking feature, however, is that this action marks another step in the advance of the electric industry along co-operative lines. It represents another case of one branch of the industry expressing a desire to assist the others and accepting their suggestions. There are, of course, other factors in our business that need to be adjusted, some perhaps more important than this, but as long as we proceed in this manner, working together for each other's benefit and avoiding individual strife we need not worry but that in a short time we will succeed in eliminating these other difficulties.

Value of Good Street Lighting

IT HAS come to be quite common to say that good street lighting is the best policeman, it having been found that where there is ample light there is less crime and fewer accidents than where the illumination is sparse.

The recent lamentable race riots in Chicago brought home to the writer of this editorial, while on militia duty for over a week, the value of good street lighting and, inversely, the objections inherent in inadequate lighting. Things go on in the dark that would not occur nor could they persist in the light. It was during the dark hours of Chicago's race riots that the most serious and most numerous crimes were committed. And it was where the darkness was densest that the worst was done. The well lighted streets were the streets where disturbances were least looked for and where they could be most easily handled.

It was in the dark alleys that the incendiaries traveled the paths of destruction. It was in the shadows and the densest masses of gloom that the snipers did their deadly work. These things are expected and proved by experience. The difference between the dark and the light street was such that in most cases, for similar conditions, double the number of militia or police were required in the dark or inadequately lighted terraine that sufficed where the streets were well lighted.

What has been said—that ample street lighting is far superior to insufficient lighting on the score of safety and law and order—is quite self-evident. But what was found true in the time of riot is also true in normal times. The well lighted neighborhood needs less policing than the neighborhood where the lighting is deficient. The investment in street lighting is a good investment when balanced against the police payroll.

And there are many other items on the credit side of the street-lighting cost—items difficult to valuate because less tangible but none the less real—chiefly all that goes with safety and law and order. Moreover, there is the increased value to the property owner of having his residence or place of business on a bright and cheerful street instead of on a dark, gloomy and dangerous one. And to the city at large good street lighting accounts for much of the difference between attractive and repulsive streets. Finally, at small cost, it may save a city's reputation from being suddenly besmirched with a stain that its authorities and the great mass of its law-abiding citizens would gladly have avoided, regardless of expense.

The Field for Static Condensers

POWER-FACTOR correction is one of the measures offering the greatest opportunity for the central stations in the way of economies of fuel, of equipment and lines. With the war came the urgent need for improving the power-factor because doing so meant increased capacity available for useful service. While the urgency of utilizing equipment to the best advantage, that is, by reducing needless and preventable wattless current, has somewhat abated, the benefits of power-factor improvement remain. Power-factor improvement and correction are, therefore, coming in for considerable attention on the part of operating companies.

Better power-factor can be obtained by the judicious choice of motors and proper loading in many industrial plants. However, it is necessary to go further than this if the lagging wattless current is to be reduced to a desirable amount. This means that synchronous motors, synchronous converters and static condensers are finding increasing application in industrial load centers.

The field for the synchronous converter for power-factor control is rather limited, as is well known, and the synchronous motor and the static condenser only are available for general application. It is only of comparatively recent date that the static condenser has found favor, it having come into commercial usage in this country only quite recently. It has been employed in Europe, however, for a somewhat longer period and with satisfactory results.

The chief objection to the static condenser is that for a given frequency and applied voltage the power-factor, hence the leading current, is a fixed quantity. This means, of course, that the static condenser will improve low power-factor but cannot correct it by varying the wattless current component. This shortcoming of the static condenser eliminates it from consideration in certain classes of service, but really is not a very serious drawback in other instances. For example, if the average power-factor of an industrial load center is 65% and the installation of a static condenser enables the average power-factor to be raised to 90%, the fact that adjustable gradations cannot be readily obtained is really immaterial. It is a case of power-factor betterment as contrasted with power-factor control or voltage regulation. For the former the static condenser may be the solution; for the latter the synchronous condenser is the solution.

Experience seems to show that for installations up to about 1000 kv-a. where power-factor betterment is sought, the static condenser may be preferable to the synchronous condenser. Power-factor betterment is obtained without human attendance or supervision; once the condenser is installed it can be forgotten so far as concerns operation. The efficiency of the static condenser is higher than that of the synchronous condenser and the cost more and more in favor of the former.

There is no doubt but that the static condenser meets a certain condition admirably. This condition is quite general but the suitability of the static condenser is not generally appreciated to the same extent as is its unsuitability for certain purposes. For power-factor betterment up to, say, 1000 kv-a. in localities remote from personal supervision the static condenser is deserving of most careful consideration.

Return of the Wires

TELEGRAPH and telephone wire systems of this country have been released from Government operation, the change having taken place at midnight of July 31. From this time we predict gradual but noticeable improvement in both these classes of service. During the year of Government control, due to unavoidable conditions growing out of the war, both equipment and trained personnel were greatly depleted. Now that the men are steadily coming back from service overseas and equipment tied up for war service is being released, we believe there will be steady improvement in service to at least the standards formerly prevailing.

The two big telegraph companies, the Western Union Telegraph Co. and the Postal Telegraph-Cable Co., both have announced to the public through their presidents return of their properties to the management of the owners, and the latter company states its rates will be reduced 20% to the point where they were before the Government assumed control.

In the telephone industry, as represented by the Bell System, the announcement of the change and all that was involved during the past year was made substantially as follows:

"A year ago today we were at war. Labor and materials needed for both telephone operation and construction were turned to military uses. Some materials were so vital to the carrying on of the war that even the work of providing telephone facilities for the Government was retarded and no part of them could be spared for commercial telephone purposes. No less vital was the Government need for those skilled to create, maintain and operate the vast intercommunication system necessary in modern warfare and in the conduct of the vastly increased Government services. Thousands of telephone men were already at the battlefront. Thousands more were under arms, and still telephone experts and skilled operators went into the service of the Government and contributory industries by the tens of thousands. The reserves of plant and equipment were drawn upon until they were entirely used up, and the experienced staff was gradually depleted. To find others to take the places of those who had gone was difficult, to train them takes time. During the year came victory and the armistice; and instantly the business world sprang into intense activity. The demands for telephone service passed all former records. To replace the exhausted reserves which had been carried for just such purposes and to replace the skilled forces to meet this unprecedented emergency, there began a rush for construction, for readjustment, for high-pressure repairs, for feverish extensions. All these must be continued with increasing effort. * * * There are no people in any public or private endeavor who are working more tirelessly or strenuously for the common good than those of the telephone companies. Service has always been given. More of it must be given, and it must be improved. That improvement in some cases will take months. Eventually service must win the race with demand."

Before the war's demands crippled the telephone service, as well stated above, the telephone organization was satisfactorily and efficient managed. We believe the change that has now taken place will soon show a very decided and comprehensive improvement. A little patience is required on the part of all the public while the present conditions are being remedied.

Current Events

Outlet Box Numbering Standardized—Meeting a Transportation Emergency—Michigan Convention Dates Changed

OUTLET BOX MANUFACTURERS ADOPT STANDARD NUMBERING SYSTEM.

New Method Offers Many Advantages to Jobbers and Contractors in Ordering.

As further evidence of their progressiveness the group of the Associated Manufacturers of Electrical Supplies manufacturing outlet boxes recently adopted a standardized system of numbering for outlet boxes and covers. This action is the result of a suggestion made some time ago by the Electrical Supply Jobbers' Association. At that time, due to war conditions, it was not possible to make these changes. Now, however, a method of making these changes has been decided upon and new catalogs will shortly be on the market bearing the new standardized catalog numbers. Hereafter the trade will have but one number to consider as substitute numbers and cross-indexing will be eliminated. A catalog number will mean a certain definite box and this number will apply to this same box made by every manufacturer.

The method adopted is very simple and clear, there being no key to remember and no puzzles to clear up. As an evidence of this, the numbers have been so worked out that the first two numerals of the cover for a certain size and shape of box, will be the same as the first two numbers of the box itself. The box number will consist entirely of numerals. The cover will be designated by the insertion of the letter "C" after the first two numerals. The flush plate will be designated by the insertion of the letter "R" after the first two numerals.

A few of the reasons for the standardization of box numbers and the advantages to be derived from it, follow:

1.—There are at present approximately 1500 different numbers used in designation of boxes and covers of various manufacturers. There are, however, less than 200 distinct types.

2.—Each manufacturer now has his own system of numbering, although the use and general type of almost any box or cover is identical with that of several manufacturers.

3.—Both contractors and jobbers, in placing orders, rarely, if ever, take the trouble to look up and use the numbers of the manufacturer with whom the order will be placed. This necessitates the editing of orders by either the jobber or manufacturer and necessarily results in numerous errors. On orders received from contractors, the jobber will often substitute the numbers of such boxes as he may have in stock, for those specified on the order, if shipment is to be made from stock, or, in case direct factory shipment is to be made, forward the order as received to the manufacturer with whom he may be placing his box orders at that particular time. This is invariably done unless the purchaser insists upon the particular make of boxes specified.

4.—The types and styles of boxes and covers have become so standardized as to be almost on the same basis as sizes of conduits. There is, therefore, no more reason why different numbers should be used to designate the same box as manufactured by different manufacturers than that different numbers should be used to designate the sizes of conduits.

5.—With the various box manufacturers using separate numbering systems, it is now necessary for the device manufacturer to use as much space in listing the boxes or covers with which their receptacles, switches, attachment plugs, etc., may be used as to list the articles themselves. This is also applicable inversely; about as much space is used in the catalogs of the box manufacturers in listing the devices as in listing the boxes and covers themselves. Then, again, it is the almost universal custom of the various box manufacturers to list the corresponding numbers of competing manufacturers. To do this requires additional space.

6.—For the box manufacturers to furnish the device manufacturers with the necessary data for a proper listing involves an enormous amount of detailed research work for the design, engineering and drafting departments of each. Also voluminous correspondence and consequently errors are frequent. Both labor and errors will therefore be reduced to a minimum by a standardization of numbers.

7.—If the various manufacturers adopt a standard set of numbers it will effect a considerable economy in catalog costs, and, in addition, reduce the volume of jobbers' catalogs. Separate sheets are now issued by the National Electrical Supply Jobbers' Association, to show the lines of the several manufacturers. By the adoption of a standard set of numbers, these could be consolidated and one set of sheets used to show the lines of all manufacturers. This would reduce the volume of the association catalog by from 100 to 200 pages. The same would apply to the data sheets issued by the National Association of Electrical Contractors and Dealers.

8.—The reduction in the volume of sheets would be particularly appreciated by jobbers' salesmen, as it would considerably reduce the weight of the catalogs which they have to carry.

9.—A jobber, in getting out a new catalog, would feel no hesitancy in listing a standard set of numbers, cuts, etc., for they could be so listed and his orders placed with any manufacturer. At the present time jobbers are frequently carrying the listing of one manufacturer's line and furnishing boxes of some other manufacturer.

10.—Separate numbering systems, as now used, give recognition to substitutes, which, at best, is a bad practice and not to be encouraged. For if encouraged in one line, as at present in the outlet box line, leeway is allowed for substitution in all lines.

11.—The adoption of a standard numbering system would prove educational to all in the electrical business, for contractors, salesmen, wiremen, clerks, etc., would soon become familiar with any system adopted and know that an XYZ box was a box of a particular type and for a certain use. With many different numbers, as is now the case, this is impossible.

12.—While some advantage might now accrue to the various manufacturers through familiarity of portions of the trade with their own "pet" numbers, the adoption of a standard set of numbers would prove reciprocal, and each manufacturer would benefit in about the same proportion.

13.—The adoption of a standard set of numbers would in no way interfere with the various manufacturers playing up the strong points of their own lines, such as finish, detailed construction, materials used in manufacture, etc. As a matter of fact, these features could be emphasized more than is now possible. In ordering, a contractor, if he wanted some particular make of box, could specify by giving the name or brand and then list the standard numbers desired. As indicated in a previous paragraph, this would reduce substitution to a minimum, eliminate frequent errors, etc. If no particular brand was specified, jobber would, of course, understand that no preference existed, and could ship from his stock or place the order for direct shipment with his preference of manufacturers.

CHICAGO CENTRAL STATION MEETS TRANSPORTATION EMERGENCY.

Commonwealth Edison and Other Companies Find Electric Truck Useful in Recent Tie-up—Terms of Settlement.

The recent four-day strike of the elevated and street car men in Chicago resulted in a complete tie-up of the transportation facilities of this city and was rendered even more confusing inasmuch as it was entirely unexpected both by the public and the companies. In this emergency the officials of the various industries had to act promptly if a great industrial shutdown was to be avoided. This was done however in the vast majority of cases with the result that aside from a little confusion and annoyance practically all concerns carried on business as usual.

Prominent among the Chicago companies whose prompt efforts in transporting its employes to and from their work was particularly noticeable, was the Commonwealth Edison Co. As soon as the news of the strike became known, which was not until early Tuesday morning, the officials of that company began making their arrangements, and in a few hours had 11 automobiles on duty transferring its station operators and other station employes to the stations and to their homes.

During that same day arrangements were completed for taking care of the company's other employes. Ten routes were laid out covering practically all of the city except those parts that could be reached by train service and 30 electric trucks were assigned to these routes. Those employes who did not live near the railroads were given passes that entitled them to ride on the trucks. The trucks were fitted up with benches and seats to make them more comfortable and to permit as many as possible to be carried at one time. The average number of passengers carried on one truck was about 30 but as many as 50 were loaded onto some of them.

As the "loop" section of the city on this day was badly congested the trucks were started from points outside of this district. This congestion was considerably relieved on the second day, however, and after the first evening the passengers were carried directly to the main office of the company located at 72 West Adams street. Each truck was started at a certain time in the morning from a given point where the various employes living in that neighborhood congregated. Other employes were picked up at various points en route. In the evening the trucks were loaded at the Edison building and carried home.

The operation of the electric trucks in this emergency is especially noteworthy. Although the usage to which they were subjected was particularly severe no serious difficulties were encountered. Of course the excessive mileage they were forced to cover necessitated numerous boosting charges, but a little extra attention given to this phase of their operation eliminated any difficulty in this respect. In addition the passengers were carried much more comfortably than on the improvised gasoline buses and due to the congestion which necessitated frequent stopping, the speed was also equal to that of the gasoline vehicles.

Employes of Commonwealth Edison Co., Chicago, Use Company's Electric Vehicles for Transportation During Recent Traction Strike.

Many other large Chicago concerns, notably the department stores, used their electric trucks to good advantage during this time. No bad results were noticed from the hard usage.

At this time it might also be of interest to state briefly the terms by which the strike was concluded. The strike was called at a meeting on Monday night which was controlled by a radical element of the unions and at which a compromise offer suggested by Governor Lowden was rejected. Friday, however, a vote of the entire membership was taken which resulted in its acceptance.

The compromise offer provides for a maximum wage scale of 65 to 67 cents an hour on the basis of an 8-hour day, with time and a half for overtime. The increased expense to the traction companies will be met by an increase in fares authorized by the Public Utilities Commission of Illinois. This order permits the Chicago Surface Lines to increase its fares 2 cents, making the fare 7 cents, and the Chicago Elevated Railroads a like amount making its fare within the city limits 8 cents.

GOVERNMENT ASKED TO REDUCE ITS USE OF CABLES.

Public Ownership of Commercial Wireless Opposed by Foreign Communications Committee of National Foreign Trades Council.

The National Foreign Trade Council's committee on foreign communications, at a recent meeting, declared strongly in favor of the establishment and maintenance of adequate systems of transoceanic communications under private enterprise and for the speediest possible release of Government control of such private commercial systems as have not already been returned to their owners. At the same time the committee took measures looking to the early establishment of additional means of communication across the Pacific so as to bring to an end as promptly as possible the present intolerable conditions in transpacific cable and wireless communication.

The committee went on record as definitely opposed to Government ownership, control or operation of commercial systems or cable or wireless in time of peace; but pending the return to private operation of such commercial systems as are still under Government control, the committee favors the continuance of the Naval Radio stations in commercial service, in order to afford as much relief as possible from present conditions, especially across the Pacific.

One case reported to the committee was of the receipt of a cable from China that was 12 days old. Another case showed a delay of one month in closing a single transaction, owing to the necessity of repeating a message, mutilated as well as delayed in transmission. It was brought to the attention of the committee that there is a tendency in different Government departments to use cable or wireless at times for communications more or less routine in character and that such traffic increases the delay in transmission of commercial messages that are essential to the transaction of important international business.

The committee is calling this situation to the attention of the President and to the heads of various Government departments with the request that the volume of Government business which now takes precedence over all commercial business shall be reduced as far as practicable, and that Government messages which are not urgent should be transmitted without the right of precedence over commercial business. The committee will also ask the Government to call the attention of other governments to this situation and urges that they take similar measures in the interest of international commerce.

DATE OF MICHIGAN CENTRAL-STATION MEN'S CONVENTION CHANGED.

Program of Meeting to Be Held at Ottawa Beach, Aug. 26, 27 and 28.

The dates originally set for the next convention of the Michigan Section of the National Electric Light Association, Aug. 19 to 21, have been postponed to the corresponding days of the following week, Tuesday to Thursday, Aug. 26 to 28. This change was made necessary by the large number of members and guests desiring to attend the meeting. The Hotel Ottawa, at Ottawa Beach, Mich., where the convention is to be held, could not accommodate so large a number along with its regular summer guests until the last week in August. Reservations should be directly with the manager of the Hotel Ottawa and as soon as possible.

An interesting program covering all phases of central-station business has been arranged as follows:

The convention will open on Tuesday morning with an address to be delivered by the president of the section, Thomas Chandler, of Sault Ste. Marie. This will be followed by an address on the "New Public Utilities Bill" by James V. Oxtoby, Detroit. Two papers will then be read, one by John Swanson, Consumers Power Co., Jackson, on "More Favorable Policies Toward Consumers," and R. A. Gordon, of the Houghton County Electric Light Co., on the "Central Station and the Contractor-Dealer."

In the afternoon J. F. Mayo, of the Consumers Power Co., and H. H. Magdsick, of the National Lamp Works of General Electric Co., Cleveland, will read papers on commercial and industrial lighting, respectively.

A special session has been arranged for the evening of this day at which Harry Burton, of the Consumers Power Co., will deliver an address on safety and resuscitation, and W. A. Durgin, of Chicago, will present a lecture and demonstration on industrial illumination. Both of the talks will be suitably illustrated and in addition a moving picture, "Queen of the Waves," showing the progress of electricity in navigation, will be shown through the courtesy of the General Electric Co.

The speakers for Wednesday are as follows: A. H. Touscany, Detroit Edison Co., on "Appliance Sales in Detroit Edison Co.'s Suburban District"; H. H. Koelbel, Consumers Power Co., "Electrical Merchandising"; E. J. Copeland, Kelvinator Corporation, Detroit, "Domestic Refrigeration"; R. F. Hetton, Detroit Edison Co., "Electric Ranges, Their Sale and Operation."

In the evening a special entertainment program has been arranged at which F. G. R. Gordon, Haverhill, Mass., will speak on "Municipal Ownership."

On Thursday, J. H. Lobben, Detroit Edison Co., and J. A. Cavanaugh, Benton Harbor, will read interesting papers.

Herbert Silvester, Monroe, Mich., is secretary of the association.

ACTIVITIES OF NATIONAL LAMP WORKS ENGINEERS.

S. E. Doane, chief engineer of the National Lamp Works, of General Electric Co., Nela Park, Cleveland, Ohio, presented a paper before the sales managers of the Association of Edison Illuminating Companies at Association Island on Aug. 4, on the subject, "The Incandescent Lamp from the Manufacturer's Standpoint."

G. S. Merrill, assistant chief engineer, National Lamp Works, has been appointed chairman of the Illumination Committee of the Ohio Electric Light Association.

E. J. Edwards, electrical engineer of the National Lamp Works, was in Buffalo the week of July 28 to conduct an investigation of air and steam transmission at the plant of the Puritan Refilled Lamp Division.

H. H. Magdsick, of the Engineering Department, National Lamp Works, will present a paper on "Practical Phases of Industrial Lighting" at the convention of the Michigan Section, National Electric Light Association, at Ottawa Beach, Aug. 26 to 28.

Commercial Practice

Central Stations Show Big Load Increases—Appliance Sales Improve in South — Pittsburgh Company Reduces Rates

NORTHERN ILLINOIS COMPANY'S LOAD GROWING RAPIDLY.

Public Service Co. of Northern Illinois Also Actively Conducting Appliance and House-Wiring Campaigns.

According to present indications there is no doubt but that the year 1919 will be a notable one in the power development of the Public Service Co. of Northern Illinois. At the beginning of this year it was estimated that the probable increase in power load during the entire year would be 17,000 hp. According to the *Public Service Lumen,* the house-organ of the company, the increase during the first six months of the year has been 14,937 hp., or roughly about 2200 hp. less than the total allotment, with six months still to go. The increase from May 31 to July 5 was over 4500 hp.

The large expansion of many plants in the booming industrial districts surrounding Chicago and extending north to Waukegan and south beyond Joliet as far as Kankakee to a considerable extent, is accountable for the increase noted. But that is by no means the sole cause. Many new customers—new plants beginning operations and other hitherto unprovided with electric power—have created a demand which works into large figures. As compared with the corresponding period of 1918, the increase is over 100%. For 1917 the figures were 9806 hp. The following table is an analysis of the six months' record of 1919. It includes, as seen, the load created by electric ranges:

TOTAL CONTRACTED POWER BUSINESS.

Jan. 1, to July 5, 1919.

Div.	Customers.	H.P.	1919 Allotment.
A	43	4,080.8	3,000
C	93	636.7	2,000
D	121	2,266.7	3,000
E	30	143.6	500
F	43	4,312.7	3,000
J	64	2,166.9	3,000
K	31	262.5	1,000
L	25	134.5	250
O	17	106.6	100
R	10	139.1	150
S	21	181.8	1,000
	498	14,331.9	17,000
Ranges	62	605.5	
Total	560	14,937.4	

Among the late contracts made is one for 790 hp. additional made by the Elgin, Joliet & Eastern Railroad for use in its shops at Joliet; one with the Vitanola Talking Machine Co. at Cicero for 700 hp., one with the Coonley Manufacturing Co., also at Cicero, for 250 hp., and one with the Parrett Tractor Co., at Chicago Heights, for 380 hp. The Construction Materials Co., at Waukegan, engaged in construction work, contracted for 600 hp., and in Cicero the same concern became the user of 50 hp. The Arcady Farms Milling Co., at Riverdale contracted for 500 hp. to operate its large mills. At Chicago Heights the Calumet Steel Co. made a contract for 100 hp. and at Waukegan the Cyclone Fence Co. signed for 137 hp. additional. The Mueller Construction Co. at Cicero contracted for 50 hp., the Superior Chemical Co. at Joliet for 73 hp. additional, the Towns Elevator Co. at Evanston for 70 hp., the Macey Construction Co. at Clearing for 50 hp., the Magazine Circulation Co., Chicago Heights, for 60 hp., and E. J. Butler & Co., at Riverdale, for 70 hp.

The electric range figures are especially interesting. These appliances present so strong a case of their own that the favor with which they are received by the public is steadily increasing. In a comparatively short period 48 new range customers were added. In the week ending July 5, ranges disposed of represented a demand of 25 hp. No attempt is made to push this device in territory where the company supplies gas but considerable success has been achieved in the sale of electric ranges in the resort districts served by the company.

The increase of new business in house-wiring is also impressive. Up to July 1 the total number of houses equipped so far in the year was 969. An increase of more than 200% is represented in these figures compared with the same period of 1918. Division "J" leads the procession with 287 houses connected up. Division "C" comes next with a score of 165. Division "A" is third, its total in the report being 147 houses. Division "D" is fourth with 132 houses. Of the whole number of houses wired the owners of one-third declined to take advantage of the easy installment privilege and paid for the improvement in cash. In all the towns in the territory a close co-operation between the company and local contractors was secured and the latter's business was benefited by the company's liberal advertising. The contractors' work is not included in the above figures. In the period referred to they wired in all parts of the territory a total of 470 houses.

In addition household electrical appliances are moving out in much larger volume than last year. The record for the first six months of 1919, in fact, is in its way as notable as that made in the contracted power business of the company. The greatest demand is for labor saving appliances—irons, washers and vacuum cleaners. Throughout the smaller towns where no office is maintained, 50,000 circular letters were sent recently to customers offering an electric iron or an electric toaster on a 10-day free trial, payment for either appliance, if the user elected to keep it, to be made in small installments monthly. The response to this offer has been excellent.

The company's Sales Department is also co-operating with the Edison Electric Appliance Co., of Chicago, in the latter's campaign among the educational institutions throughout the country to encourage the use of electrical appliances in the home. Various circular letters have been sent out to the instructors of the Domestic Science Departments of the schools in the territory served by the company and its sales force is taking every advantage of this opportunity.

GREATER DEMAND FOR ELECTRIC APPLIANCES IN SOUTH PREDICTED.

Increasing Scarcity of Colored Help Results in Greater Use of Electric Labor-Saving Devices.

Largely increased sales of labor-saving electric household appliances are predicted through the South, where the domestic labor situation has taken on more of the aspects familiar in the North. Conditions in Louisville, for example, have changed radically in the last three or four years, according to Robert Montgomery, manager of the Commercial Department of the Louisville Gas & Electric Co., Louisville, Ky. "When I first came to Louisville," says Mr. Montgomery, "negro servants were so plentiful and could be employed at such low prices that it did not pay the housewife to do much of the hard work, but today you find servants difficult to obtain and they are now demanding prices such as paid for labor of this kind in Chicago. It is a condition entirely new to the Southern people, who have never before experienced difficulty in securing cheap domestic help."

In line with the increased use of electrical household appliances, the Booker T. Washington community center at Louisville is teaching negro women how to use these devices. A circular describing the course of instruction at this institution says: "The world keeps moving forward all the time. We must all keep up with the times. If we do not we lose in comfort, convenience, time and money. The man or woman who studies and learns to use the new way of doing things and the new inventions is the one who gets ahead in the world, makes the most money and has the largest amount of leisure."

DUQUESNE LIGHT CO. REDUCES RATES FOR RESIDENCE SERVICE.

Lower Rates of Pittsburgh Company Expected to Stimulate House-Wiring Campaign.

A reduction in the rates for residence service amounting to approximately 20% was put into effect July 1 by the Duquesne Light Co. of Pittsburgh. The new rate provides for a charge of 8 cents net per kw-hr. for the first 30 hours' use of maximum demand in any month. The next 60 hours of demand will be charged for at the rate of 6 cents per kw-hr. and all current consumed in excess of this amount in any month will be charged for at the rate of 3 cents per kw-hr.

The maximum demand for such service will be determined by the number of lamp outlets on the following schedule: The first 10 lamp outlets are rated at 300 watts; the next 20 lamp outlets are rated at 20 watts each; lamp outlets in excess of 30 are rated at 10 watts each. Every lamp socket excepting those contained in portable and floor lamps is counted as a lamp outlet, as well as all baseboard, floor and similar outlets. The service charge residential rate schedule remains unchanged.

In order to apply this new rate, it was necessary to take a census of the lamp outlets for every residential installation now on this schedule, approximately 65,000. For this purpose a staff of 60 census men was organized and began work on June 23. It is anticipated that this census will be completed within 90 days.

Reductions were also made at the same time in the wholesale power rates for the company but these were much smaller than those made in its residential service. These changes will effect the energy charges only.

Coincident with the house-wiring campaign being conducted by the company, these liberal reductions in its residence rates should bring about an enormous addition to its residence consumers. In the early part of this year the Wiring Department of the company, under the supervision of Howard H. Wood, started a campaign to secure the wiring contracts for 2000 old houses by July 1. This campaign was very successful, 2065 contracts being secured in Allegheny county and 325 in Beaver county during this period. With the impetus afforded by the reduced rates, the campaign period has been extended and a new mark of 5000 house-wiring contracts for the year ending Dec. 31, 1919, has been set and according to all indications will be reached with a good margin to spare.

SOUTHERN CALIFORNIA EDISON CO. SHOWS BIG LOAD INCREASE.

Prospects Also Particularly Good According to Reports from District Offices.

According to the reports from the various district offices of the Southern California Edison Co., Los Angeles, Cal., the present year promises to be a notable one in the annals of that company. During the past month many of these districts have secured considerable increases in their power loads and the prospects for the future development along these lines is also particularly good.

The Oxnard district during May and June signed up more than 300 hp. while the Whittier district during the latter month added 224 hp. to its lines. The San Bernardino district recently completed the installation of 500 hp. additional, for the Fontana Land Co. for pumping purposes and Pomona just completed the installation of 100 hp., replacing a steam plant. The station output for June at Lancaster was 804,000 kw-hr. Thus far this year this district has added 388 hp. to its lines and still has 182 hp. yet to be connected. The Ventura district reports that the power business for June more than doubled that of the same month in 1918.

Since April 1, 1919, 377 shares of the company's stock have been sold to the employes of the Los Angeles office and 190 shares disposed of through this office to the public.

CRIPPLE CREEK SHORT LINE TO BE ELECTRIFIED.

Electrification Expected to Effect 20% Saving in Operating Expenses—Central-Station Service to Be Used.

Work on the electrification of the Cripple Creek Short Line railroad, which operates between Colorado Springs and the gold mining camps in that section, is expected to begin early in September. Electric power for the operation of the road, according to a recent announcement, will be purchased from two central-station companies, one of which is to be the Arkansas Valley Railway, Light & Power Co. By electric operation the railroad expects to reduce its operating expenses 20%.

Contracting-Construction

New Chicago License Ordinance—Considerations in Selecting an Electrical Contractor—Iowa Contractors to Meet

NEW CHICAGO ORDINANCE COVERING LICENSING OF ELECTRICAL CONTRACTORS.

Principal Features of License Law to Become Effective Sept. 1.

The new ordinance governing the licensing of electrical contractors, fixture hangers, maintenance and sign men in Chicago, which was briefly outlined in a previous issue, has been passed and will go into effect Sept. 1, 1919. The changes in the new ordinance are substantially as follows:

Any person or corporation making application for permits must first file with the Commissioner of Gas and Electricity an application containing an affidavit stating that the work to be done under such permits will be under the supervision of a person who is not less than 21 years of age, who has a thorough knowledge of electrical construction and who has had not less than four years of practical experience in installing or maintaining electrical wires and apparatus in the class mentioned in the application for license and who shall also have regularly passed the examination as provided for hereinafter. The application shall be made upon a form prepared and approved by a Board of Examiners, to be appointed by the Mayor for the purpose of inquiring into and ascertaining the qualifications of the applicant and of the supervising electrician, as provided herein. Such application shall contain the name and signature of the person under whose supervision the work is to be done, together with two indorsements from responsible citizens, made under oath, that such person possesses the qualifications above designated. Upon filling such application in proper form and upon the deposit of an amount equal to the license fee for the class of license being applied for, and upon the supervising electrician successfully passing the examination provided for, the deposit will be transferred to the City Collector, which deposit the City Collector shall receive as the license fee for the said applicant, and the Commissioner of Gas and Electricity shall issue, or cause to be issued, the license applied for, which license shall entitle the licensee to obtain permits to do such work as shall be within the classification covered by such license. The license fee for the first year for a general electrical contractor shall be $200 with a renewal fee of $50 for each year. The license fee for the first year for electrical construction only shall be $100 with a renewal fee of $25 for each year. The license fee for the first year for a fixture license, including such persons or corporations doing fixture work only, shall be $100, with a renewal fee of $25 for each year. The license fee for the first year for a sign license, including such persons or corporations doing sign work only, shall be $25, with a renewal fee of $10 for each year. The license fee for the first year for a maintenance license, including such persons or corporations doing maintenance work in buildings owned or controlled by such persons or corporations, shall be $25, with a renewal fee of $10 for each year. The above classification of licenses and the fees pertaining thereto shall not immediately apply to those certificates of registration in existence but shall apply at the expiration of the period for which they are issued, at which time a renewal fee in accordance with the above classification must be paid before the renewal is made.

Prior to the issuance of a license for general electrical contractor, electrical construction, fixture license and sign license, the applicant shall file with the City Collector of the City of Chicago an indemnifying bond with good and sufficient sureties in the penal sum of $5000, such bond being payable to the Commissioner of Gas and Electricity of the City of Chicago, for the use of those with whom the applicant shall thereafter contract to do work, to indemnify for damages sustained on account of failure to perform the work contracted for, in accordance with the provisions and requirements of the City of Chicago, relating to the installing, operating or maintaining of electrical wires or apparatus. The filing of the above mentioned bond shall be required previous to the issuance of any original license or the renewal of any Certificate of Registration in existence at the time of passage of the ordinance.

For the purpose of ascertaining the qualifications of the applicant and of the supervising electrician, the Mayor shall appoint an Examining Board of five members to consist of the following: Commissioner of Gas and Electricity, chairman; one member to be selected from the Board of Underwriters of the City of Chicago, one member to be a general electrical contractor regularly engaged in the contracting business in the City of Chicago, one member to be a journeyman fixture hanger who has had at least five years of practical experience, and one member shall be a journeyman electrician who has also had at least five years of practical experience. Such members shall hold office for a period of one year or until their successors are duly appointed. It is also provided that the Examining Board shall have power to adopt the necessary rules and regulations for the licensing of electricians and for the examination of supervising electricians and such examinations shall be conducted by the oral and written method and the judgment of the board as to whether or not an applicant or supervising electrician is qualified and has sufficient experience and knowledge for the particular class of license applied for shall be final.

Where a Certificate of Registration is in existence at the time of passage of this ordinance a renewal of such Certificate shall only be made within the classification previously placed on such Certificate by the Commissioner of Gas and Electricity, and for the purpose of transferring to or renewing a Certificate of Registration in any other class, as provided for herein, the Supervising Electrician must submit to and properly pass an examination such as will determine his experience and qualifications to act as Supervising Electrician in the particular class of business to which he desires to transfer.

The ordinance also provides that all licenses issued are transferable, but such transfers cannot be made until transferee has complied with all its terms. The supervising electrician may also be replaced at any time, providing the new man shall comply with the terms. No fee is to be charged for such transfers.

The Board of Examiners will meet as often as it deems necessary and must act on all applications within 45 days from the date of filing. Applications must be filed 15 days before the time set for the examination. The Board of Examiners also may recommend the revocation or suspension of a license for any violations. A license may be suspended by the Commissioner of Gas and Electricity for a period not to exceed 30 days and may be revoked by the Mayor.

The ordinance also provides for the following payment of fees:

Wiring only for lighting circuits (not including fixtures, sockets or receptacles). For the inspection of each complete branch lighting circuit of 660 watts or less a sliding charge is made ranging from $1 for the first circuit to 40 cents for each circuit over 25. For the inspection of each complete branch lighting circuit of larger capacity than 660 watts the charge shall be in proportion to the wattage of such circuit. For the inspection of additional outlets on existing circuits: 20 cents for each outlet on which a socket, receptacle or fixture will be attached.

Electrical fixtures, sockets and receptacles (not including the circuit feeding same). For the inspection of fixtures, sockets or receptacles for lamps of nominal 50 watts capacity the charges range from 50 cents for from 1 to 15 lamps to 25 cents for each group of 25 or less in quantities above 200. For lamps of larger or smaller capacity the charge shall be in proportion to the wattage of the lamp. For the inspection of both circuit wiring and fixtures, sockets or receptacles: The aggregate sum of the fees as shown above for wiring and for electrical fixtures.

For the inspection of each electrical horsepower of 746 watts used for mechanical or other purposes than above mentioned, the sum of $1 for each horsepower from 1 to 5 hp., inclusive for each of the next succeeding 5 hp., 75 cents; for each of the next succeeding 5 hp., 65 cents; for each of the next succeeding 10 hp., 55 cents; for each of the next succeeding 25 hp., 50 cents; for each of the next succeeding 200 hp., 25 cents; for each of the next succeeding 250 hp., 10 cents; and for each additional horsepower, 5 cents.

Inspections of electric lights, other than electric signs as herein defined, placed on a public street or alley for the purpose of illuminating the same, temporary installations for show window exhibitions, conventions and the like, underground or overhead wires and apparatus, and all other inspections not specifically provided for herein, shall be charged for according to the time required for such inspections at the rate of $1 per hour. Reinspection shall also be charged for at this rate.

The fee for all signs projecting at right angles or obliquely from the building against which same are placed, whether such signs are vertical or horizontal, and not being flat signs as hereinafter described, shall be computed at the rate of 15 cents per annum per square foot of sign surface on each illuminated side of such sign. The fee for all signs placed against a building running parallel thereto and not projecting obliquely or at right angles therefrom shall be computed on a sliding scale, based on lamps of 50 watts capacity, varying from 10 cents each for the first 25 lamps to 4 cents for each additional lamp above 300.

IMPORTANT CONSIDERATIONS IN SELECTING AN ELECTRICAL CONTRACTOR.

Interesting Pamphlet on This Subject Being Distributed by Louis Kalischer, Inc., Brooklyn.

"Important Considerations in Selecting an Electrical Contractor" is the title of a pamphlet recently published by Louis Kalischer, Inc., 1225 Myrtle avenue, Brooklyn, N. Y. This pamphlet, which is intended for distribution among manufacturers and users of industrial apparatus, brings out very clearly the importance of properly selecting a competent electrical contractor to install the electrical equipment for an industrial enterprise.

"The electrical equipment of an industrial plant," the article states, "is conceded to be of vital importance to its successful commercial operation.

"The maximum result of an efficient design in manufacturing is based on continuity of service, and it is within the range of possibility that the best and most carefully thought out plans to accomplish this may be seriously affected by improper or inadequate consideration of the electrical equipment.

"Changes in manufacture to accomplish higher efficiency may be met at times without great effort or expense, but this does not always apply to the electrical equipment, therefore, greater care must be exercised in the original layout. Furthermore, the entire electrical equipment of a plant is installed at the inception of the building project and is considered a building or one-time operation. In selecting an electrical contractor to undertake the work, it is important that the results of previous experiences in the same or similar lines of business should be taken advantage of, as an inefficient design of a plant constitutes a continuous loss.

The article then relates the experience of Louis Kalischer, Inc., and describes the facilities of this company which enable it to meet these requirements satisfactorily. In addition to a competent, practical engineering force this company has also put into effect an up-to-date follow-up system by which a check is kept on material and apparatus deliveries from manufacturers and eliminates to a considerable extent the difficulties often encountered by poor deliveries. "Service Plus Satisfaction to the Customer" it explains, has always been the keynote of the business.

This company is now erecting a new building at 288 Livingstone street, Brooklyn, where it will conduct a modern electrical retail store and carry a complete stock of all electrical devices of standard merit.

IOWA CONTRACTORS MAKING PLANS FOR ANNUAL CONVENTION.

The Iowa State Association of Electrical Contractors and Dealers plans to hold its next annual convention in Sioux City, Iowa. The exact date of the meeting has not been definitely determined as yet but indications are that it will be held during the last week of September. F. Bernick, Jr., Oskaloosa, Iowa, is secretary of the association.

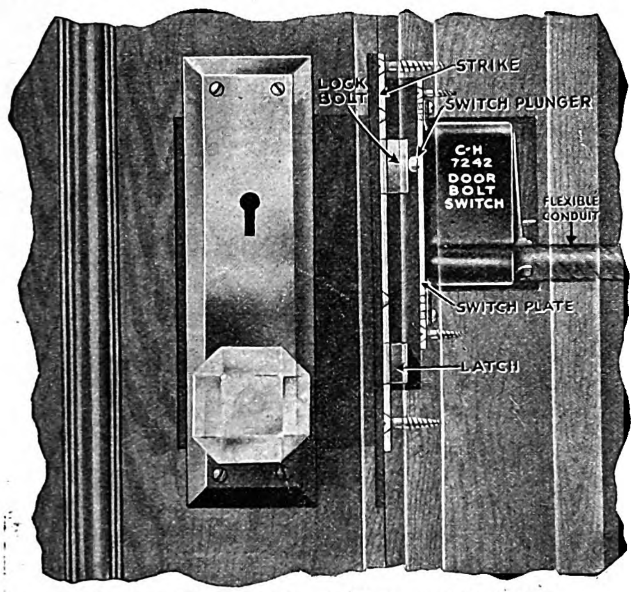
New Appliances

Door-Bolt Switch for Hotels — Cutter Outdoor Line and Disconnect Switches — Volt-Ammeter for Automobile Use

New Door-Bolt Switch for Hotel Guest Rooms.

To prevent the wasteful use of electric light in their guest rooms, hotels and clubs often display in each room a sign reading, "Please turn out the lights when leaving the room." The new C-H door-bolt switch, which has been developed by the Wiring Device Department of the Cutler-Hammer Manufacturing Co., Milwaukee, Wis., accomplished what the sign aims to do. When the occupant of a room leaves and locks the door from the corridor side, this switch is operated by the lock bolt, the lights within the room are cut off, and the wall switch made inoperative. When the door is unlocked the wall switch may be used to control the lights. This new door-bolt switch, although similar in shape to the well-known C-H door switches, is operated by the lock bolt of a two-bolt lock, such as is generally used in hotels. The new switch is mortised in the lock side of the door jamb in back of either a flat or box strike, and is connected in series with the regular wall switch that controls the lights within the room. As it is customary to install the regular wall switch conveniently near the door, very little additional wiring is necessary for the installation of the door-bolt switch.

The accompanying illustration shows the details of this new device and how the movement of the lock bolt will push against the switch plunger and thus open the switch. In this phantom view the switch is shown mounted in the door jamb with wood screws. The switches can also be mounted on the strike by using spacers and machine screws, the latter furnished with the strike, two holes being tapped in the switch plate for the screws. Being purely a mechanical device, the life of this switch should be as long or longer than the ordinary wall switch. Since it works with the locking of the door, the reader will readily appreciate that its regular use is practically automatic and that it will be instrumental in the saving of much lighting current to the hotel manager.



Phantom View of New C-H Door-Bolt Switch.

New Line of Outdoor Load and Disconnect Switches.

This is the age of urban and interurban electric power distribution. Not only do many city employed people live far out in the country and require city conveniences, but the farmer is fast becoming a convert to the use of electric power and light. Many manufacturers are moving out also to obtain the advantages of cheaper sites, lower taxes, lower insurance rates, more stable labor, etc., and the factories are especially good electric power customers.

Then, too, the small rural towns and communities can be served with a profit to the public utility if the cost of the substation for stepping down transmission voltages can be kept reasonably low and not require continual care by an operator. During the past ten years this business has been rapidly expanding because of the development of outdoor protective and switching equipment. There still remains much to be desired in the way of reliability for outdoor equipment. The utility man will therefore be especially interested in the following announcement:

The George Cutter Co., South Bend, Ind., is placing on the market the first items of a line of high-tension transmission equipment which will be sold under the trade name of "Clear Break Equipment."

The first of these items is an outdoor, air-break switch which is designed for rupturing load current under the most severe conditions. This switch is designated the type "T" switch and will be furnished regularly in 150-200-ampere capacities and for rated voltages of 22,000, 33,000, 44,000, 55,000 and 66,000. Developments now under way will take care of voltages of 90,000 to 150,000 and higher, if desired.

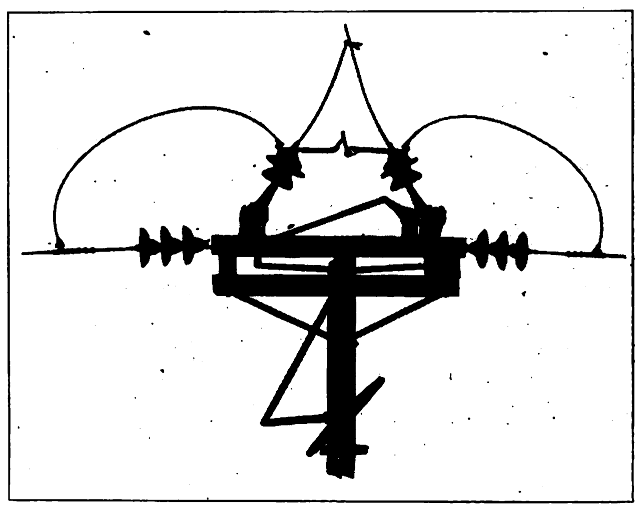


Fig. 1.—Cutter Type "T" 33,000-Volt Switch in Closed Position.

These switches will be furnished hand-operated, automatic or non-automatic overload release, also motor-operated, automatic or non-automatic overload release. Inasmuch as standard series and shunt-trip mechanisms will be used in connection with standard circuit-closing relays, time-element devices are readily applicable. The switches may be obtained in one, two or three-pole arrangement and are readily mounted on wooden poles or steel towers.

Regularly the 22,000 and 33,000-volt switches are designed for mounting on a framing arranged on one pole. The 44,000 to 66,000-volt switches, which are considerably heavier and with wider phase spac-

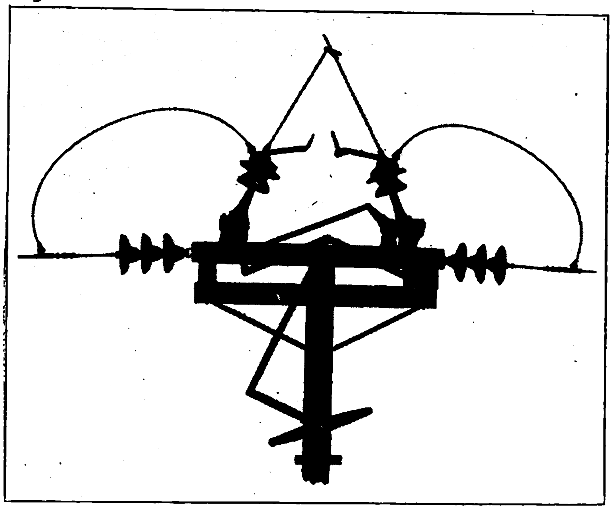

Fig. 2.—Same Switch Partly Opened with Auxiliary Contacts Ready to Open.

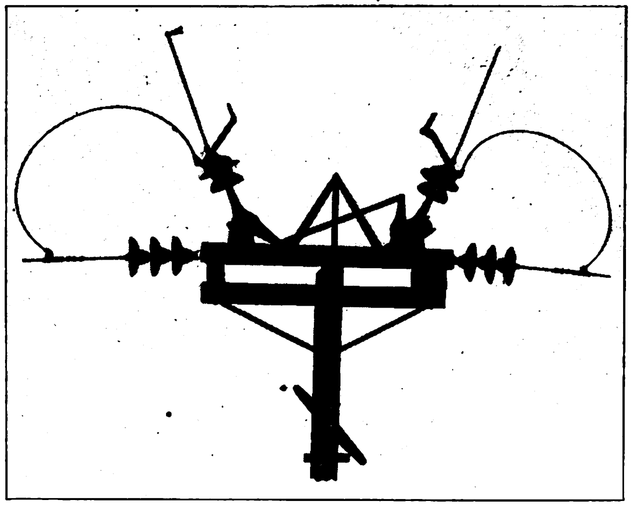

Fig. 3.—Same Switch Entirely Opened, Showing Wide Separation of Contacts.

ings, are arranged for mounting on two wooden poles. The construction, however, is such that they are readily adapted to suit almost any condition.

The second item to be announced at this time is a line of switches known as the type "D," which are designed for disconnect purposes only but are arranged to operate all legs of the switch simultaneously from a ground lever which may be readily locked in either the open or closed position.

The especially novel feature in connection with the type "D" line of switches is the fact that only a pole and the strain insulators for dead-ending are required for mounting the switch. The switch framework, consisting of 3 by 4-inch angles, furnishes the necessary double arming for dead-ending the lines on each side.

These switches are furnished with insulators rated at 22, 33, 44, 55 and 66 kilovolts and all give a little more than 2 ft. of clear separation between live parts when switches are in the open position. No auxiliary contacts are provided on the type "D" line of switches to prevent blistering of the main contacts in case of opening with line current.

A very noteworthy feature of both the types "D" and "T" switches is what is known as the spring type of contact for the main current-carrying capacity. These contacts are identical for all of the type "T" and "D" switches rated from 22 to 66 kilovolts and consist of a multiplicity of parallel spring wires, each seating in a "V" notch in the other member of the contact and arranged to be bent back when in the closed position so as to exert a pressure against the notch. This insures a constant large carrying capacity by each one of these wires, which under tests of 10 to 12 times their rating have shown no injurious results. This contact was designed to meet the great demand for a contact which would stand up and continue to give satisfactory service under ice conditions and would also not weld electrically and prevent opening. Good seating is insured by a wiping action.

The type "T" switch is provided with an auxiliary or arcing contact (not a horn), which ruptures the line current at its tip when opening. The arc is thus drawn at a point well above the grounded framework and is drawn in a vertical plane parallel to the phases. This prevents shortening of phase spacing in opening and this, in connection with the quick, long break given, insures prompt interruption of the current.

The 22,000 and 33,000-volt type "T" switches have a phase spacing of 6 ft. and in opening stretch the arc to 6-ft. length. The 44, 55 and 66-kilovolt type "T" switches have a phase spacing of 8 ft. and in opening stretch the arc to 8-ft. length. The 90 to 150-kilovolt type "T" switches will be furnished regularly with phase spacings of from 12 to 15 ft. and will stretch the arc in opening from 14 to 18 ft.

On all of the type "T" and "D" switches for voltages from 22,000 to 66,000, standard pin-type insulators with ¾-in. separable thimbles are used and the insulator caps are held on by especially formed rings in the groove under which setscrews in the cap are engaged, forcing the cap down rigidly onto the top petticoat of

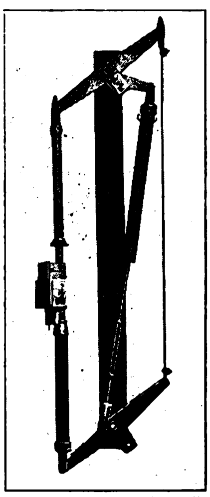

Fig. 4.—Hand-Operated, Automatic Overload Release and Special Operating Mechanism.

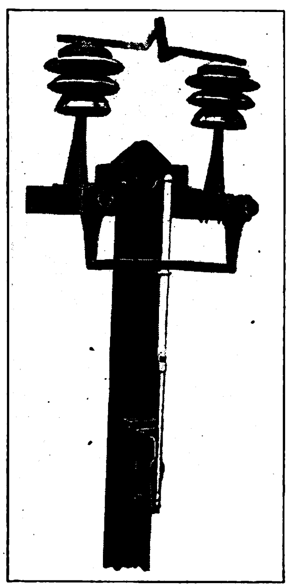

Fig. 5.—Cutter Type "D" 44,000-Volt Disconnected Switch in Closed Position.

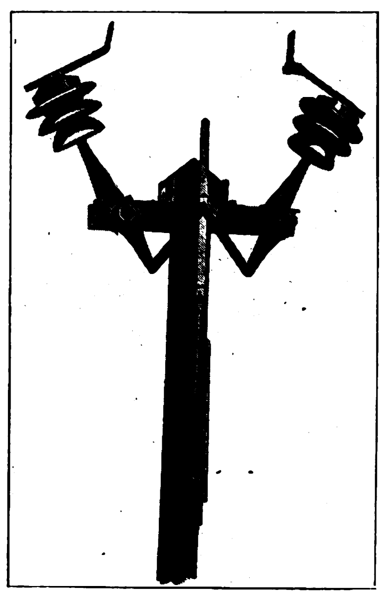

Fig. 6.—Same Switch in Wide Open Position.

the insulator. The setscrews exert no direct pressure against the porcelain. Type "T" switches for voltages above 66,000 will be equipped with built-up post-type insulators.

Any of the type "T" switches can be furnished with outboard insulators mounted on an extension of the channel-iron support and with rigid pantograph-type line connector between the rotating and the stationary insulators. This latter arrangement is for use where switches are units of power and substations and line spans thus terminated.

Fig. 1 shows one leg of a type "T" 33,000-volt switch in closed position with the upper operating mechanism for hand operation. The ground lever is not shown. Fig. 2 shows the same switch partially opened until the main contacts are disengaged sufficiently to prevent re-establishing of the arc and the auxiliary contacts, at their tips, just at the point of separation. Fig. 3 shows the same switch in the wide open position and the long break between auxiliary contacts. The action of the No. 0 copper-clad flexible line connectors is readily seen from these three cuts.

Fig. 4 is a hand-operated, automatic overload release and operating mechanism for mounting in place of the regular ground hand lever. This mechanism is equipped with trip coils for operating from the secondaries of current transformers or may be furnished with mechanical trip from series of trip coils mounted on top of outboard insulators or any other suitable adjacent insulators.

Solid steel wire is used to connect the two ends of the upper operating lever on the switch Fig. 1 with the corresponding two clevis ends on the top lever of this automatic device, which is placed directly below at the foot of pole. The lower lever arm of this automatic device is locked in its present position by means of a latch and bolted on the arm, which are not shown. In case of overload either one or two strip coils, placed in the housing, midway up on the left, will trip a catch, which is also in this housing, and allow a heavy coil spring in the pipe housing on the right side to rotate the upper lever through 90°, the lower lever arm remaining fixed until released by the operator and brought back to again engage the trip catch. The switch can then be closed again, if desired, but cannot be held closed in case the overload condition still exists.

Fig. 5 shows one leg of the type "D" switch for 44,000-volt service with ground operating lever and push rod shortened to show in the picture. This view shows switch in the closed position. Fig. 6 shows the same switch in the open position.

The type "D" switch is furnished without the regular flexible line connector except when ordered. As the angle of rotation is small, the use of solid hard-drawn copper wire bolted rigidly to the switch arm and the line wire, with loop for flexibility, is ample.

It will be noted that holes are provided in the ends of the cross angles for terminating line wires through strain insulators. The stringer angles on the type "D" switch are extended on each side of the pole so as to give a 3 ft. 8-in. phase spacing on the 22,000 and 33,000-volt switches and 6 ft. on the 44,000 to 66,000-volt switches. A double angle brace is provided for each stringer angle, giving ample rigidity of construction.

This equipment was designed by an engineer who has spent years in the study of outdoor substation equipment with a view to eliminating troubles being encountered, and these troubles as summarized may be stated as follows:

Failures are due generally to:

1. Striking between phases when opening.
2. Striking to ground when opening.
3. Contacts burning and welding so they cannot open.
4. Contacts freezing from ice so they cannot open nor flow.
5. Mechanical shock or blow to insulators, causing breakage and failure of same.
6. Insulators often under torsion, causing separation of units and failure.
7. Dependence on horns to carry arc upward and stretch to rupturing length.

It is the belief of the engineering department of the George Cutter Co. that to a large extent the difficulties and failures enumerated above have been eliminated. This is borne out by the fact that several of the type "T" switches have been giving excellent satisfaction for more than five years. A number of improvements have been added to the original design which add materially to the merits of the design and to the serviceability. Further, at the National Electric Light Association convention held at Atlantic City, N. J., May 19-22, where samples of this equipment were exhibited, engineers were unanimous in their high praise.

New Automobile Type Volt-Ammeter for Testing Lighting and Starting Systems.

Troubles in the lighting and starting systems of gasoline automobiles are not very frequent, but when they occur they are very vexatious and hard to locate. To facilitate the location of trouble it is essential to have a convenient and dependable measuring instrument for determining current and voltage.

An instrument of this type especially designed for this service has recently been placed on the market by the Roller-Smith Co., 233 Broadway, New York City. It is known as the "Handy" auto type volt-ammeter. The illustration herewith shows at a glance the appropriateness of this name, since the instrument has dimensions of only 4 by 5 by 2 in. and its weight is only 20 oz. The instrument is of the permanent magnet and moving-coil type, giving dead-beat indications and providing uniform divisions of the scale. The instrument most commonly used for this purpose has six ranges, of which three are for voltage and three for current measurement. The former include a scale of 0-75 millivolts, which is useful in making tests of commutators; a scale of 0-3 volts for testing voltages of individual dry cells or storage cells; a scale 0-30 for testing battery voltages of lighting and starting batteries of any of the usual combinations up to 12-cell batteries. The current scales are 0-3, 0-30 and 0-300, the first being used for testing current taken by lamps, ignition circuits, etc., the second for testing generator output, charging current, etc.; and the last for testing the starting current. For use as an ammeter, the instrument is provided with three shunts which are all mounted on base with suitable terminals for convenient connection to the instrument and the circuit being tested. These instruments are also made in several other ranges. A special leather carrying case for the instrument, shunt and the connecting leads can be provided at a small additional expense. These instruments are especially suitable for use in garages and service stations.

"Handy" Volt-ammeter for Automobile Testing.

Trade Activities

New Agency for Green Engineering Co. — Jewell Instrument Sales Organization — Many Electric Furnaces Sold

The Sierra Electric Co., San Francisco, Cal., has been appointed Pacific Coast distributer for the Chicago Solder Co., maker of Kester self-fluxing wire solder. Both acid-core and rosin-core solder will be carried in stock.

Boyle Engineering Co., Cincinnati, Ohio, announces that it is now occupying its new building at 2023 Reading road. This company handles all kinds of electrical equipment for automobiles, and represents 18 electrical organizations.

The Electric Appliance Co., Seattle, Wash., has moved from 118 Spring street to 1214 Third avenue, where a large store room has been fitted up for handling general electrical appliances. The company is now specializing in washing and ironing machines.

The Central Electric Co., Chicago, Ill., has issued price list 39-A, which applies to the company's general catalog No. 39 and is unique in the fact that it carries, along with the prices in that catalog, addenda pages listing new or redesigned devices that have not been previously included.

The Electric Products Co., manufacturer of Wotton battery-charging motor-generators and rheostats, vehicle motors, controllers and switchboards, Cleveland, Ohio, has just opened a branch office in Detroit, Mich., at 2306 Dime Bank building. E. H. Bridge has been placed in charge as district manager.

Surf Manufacturing Co., Milwaukee, Wis., manufacturer of electric washing machines, has acquired 14,000 sq. ft. of the building at 109-113 Clinton street. The new company, which has recently completed its organization, is capitalized for $100,000, and expects to build more than 5000 machines during the coming year. It is said that the product of the company employs an entirely new principle of mechanical washing. The officers of the company are as follows: O. F. Fischedick, president; J. Hoffman, vice-president; A. Schmidt, secretary, and A. W. Kerhan, treasurer.

Cutler-Hammer Manufacturing Co., Milwaukee, Wis., is furnishing to dealers who handle C-H electric irons and other C-H electrical appliances a new four-page two-color folder which has for its title "The Aristocrat of the Laundry," illustrative and descriptive of the C-H electric iron. These irons are made in four sizes, 3, 6, 7½ and 9 lb., three of which are illustrated in the folder. The cords of all C-H irons are equipped with the C-H 7050 switch, which is being advertised in the national and trade media as well as by direct mail. Space is provided on page 4 of the folder for the dealer's imprint.

International High-Speed Steel Co. announces the removal of its New York City office to 294-6 Lafayette street—129-31 Crosby street. The general business of the company will hereafter be conducted from its works at Rockaway, N. J.

Simplex Electric Heating Co., 85 Sidney street, Cambridge, Mass., is sending out two new and attractive display cards, 9¼ by 11 in., printed in colors, one featuring the Simplex electric iron and the other the No. 27 domestic range. These are being sent to the leading distributers of Simplex products with the request that they order for themselves and their customers the quantity which they can use to advantage.

The American Steam Conveyor Corp., Chicago, Ill., has just announced the appointment of H. S. Valentine as sales engineer in charge of Philadelphia territory. An office has been established in the North American building, Philadelphia. Mr. Valentine is an experienced mechanical engineer and was connected with the Link-Belt Co., Philadelphia, for five and one-half years, with the Brown Hoisting Machine Co., and Yale & Towne Manufacturing Co. for six years, and with the Badenhausen Co. for one year.

Novo Engine Co., Lansing, Mich., has issued an instruction book and repair list for Novo engines (No. 819); this is a valuable reference book for those employing this type of engine. A detailed description of the principles of operation as well as instructions for installation and operation are given, accompanying which are many diagrams to clarify the text. The company has also issued Bulletin No. 18 entitled "Novo Reliable Power" containing a detailed description of the Novo engine. It points out the salient features of this engine and the advantages of the vertical design. Illustrations of various types of engines are included.

Allis-Chalmers Manufacturing Co., Milwaukee, Wis., has issued Catalog No. 107, illustrating and describing its ore concentrating machinery and equipment. This includes crushers, rolls and ball granulators, sizing and classifying apparatus, concentrators, elevating, conveying and transmission machinery, power-generating and electrical equipment, pumps, etc. The catalog contains 112 pages, printed on a very fine grade of paper and the back inside cover gives a list of the district offices, foreign district offices, Canadian representatives and foreign sales agencies. Page 112 gives an alphabetical list of Allis-Chalmers' principal products. The cover is in four colors and shows a typical concentrating mill.

Blaw-Knox Co., Pittsburgh, Pa., announces the appointment of K. C. Murray as an engineer-salesman in the Knox department. Mr. Murray is a graduate of the Pennsylvania State College and was for many years connected with the Carnegie Steel Co., both at the Edgar Thompson Works, Bessemer, Pa., and in the sales department. He will, for the most part, devote his activities to the steel plants in the Pittsburgh district.

Green Engineering Co., East Chicago, Ind., manufacturer of Green chain-grate stokers and related products, announces that the firm of Bull & Livensparger has been appointed as its sales representative in Chicago and northern Illinois. They have taken charge of the company's Chicago office, 14 East Jackson boulevard, and are prepared to handle all inquiries respecting Green chain-grate stokers, Sealflex arches, steam-jet ash conveyors, cast-iron ash tanks and allied products and replacements for the same. E. H. Bull has been connected with the company as an engineer for the past seven years. D. A. Livensparger has been a member of its sales force for the past nine years.

Jewell Electrical Instrument Co., Chicago, during the past two years has been pursuing a policy of concentrated sales work with representatives in the larger cities and electrical manufacturing centers in the United States, with the result that today it has a sales organization, the personnel of which is second to none. Frederick Rall, 19 Park Place, New York City, covers the state of New York, New York City and adjacent territory, George E. Linton, the Boston territory with offices at 10 High street, Boston Mass., & Benjamin B. Baseler 1716 Sansom street, Philadelphia, Pa., the territory of Philadelphia and Eastern Pennsylvania, Western Pennsylvania is covered by the Superior Engineering Co. located at Jenkins Arcade, Pittsburgh. H. L. Porter, 1202 Illuminating building, Cleveland, Ohio, covers Cleveland and Northern Ohio. Missouri is covered by C. B. Fall Co. with offices in the Railway Exchange building, St. Louis, Mo. Minnesota territory is covered by W. F. Uhl, with offices at 505 First National Bank building, Minneapolis, Minn. More Electric Co., covers the state of Colorado, its offices being located in the Gas & Electric building, Denver, Colo. L. Brandenberger, Walker Bank building, at Salt Lake City, covers the state of Utah. Nixon-Kimmel Co., Lincoln and Main street, Spokane, covers Spokane and Eastern Washington. Burton R. Stare Co., covers Western Washington and Oregon and has offices at 325 Yesler Way, Seattle, Wash. C. F. Henderson, Call building, San Francisco, covers territory of San Francisco and northern California. O. E. Thomas Co., 625 Washington building, covers Southern California, including Los Angeles, its offices being located in Los Angeles. With the exception of Filer-Smith Machine Co., in Winnipeg, who covers Winnipeg and Western Canada and the Tokiwa Co., of Tokyo, Japan, in the Orient, all foreign representation and export business is handled by the Frank E. Watts, Inc., 50 Church street, New York City.

The Electric Furnace Co., Alliance, Ohio, has just shipped to the Dayton Engineering Laboratories, Dayton, Ohio, an electric furnace for melting and refining aluminum in the Delco plant. This furnace has a hearth capacity of 500 lb. and a melting rate of 200 lb. of aluminum per hour. It is equipped with a double charging door in the front and rear, and otherwise is similar to the standard Baily electric furnace of 105-kw. electrical capacity, and 1500-lb. hearth capacity, that is used for melting brass.

The Electric Storage Battery Co., with general offices Allegheny avenue and 19th street, Philadelphia, Pa., is distributing a new booklet, Form 881-R, devoted to its "Ironclad-Exide Battery." This booklet has been revised and brought up to date. It gives a general description of these batteries with illustrations, reviews their development, and also contains a brief history of the company, which maintains "Exide" depots in Boston, New York, Philadelphia, Cleveland, Washington, Rochester, Chicago, Detroit, St. Louis, Kansas City, Denver, Atlanta, Minneapolis and San Francisco. A corps of inspectors are constantly traveling through the country coaching users of its batteries.

Roller-Smith Co., 233 Broadway, New York City, announces that it has made an agency arrangement with L. B. Gottschall, 211 North St. Paul street, Dallas, Tex. Mr. Gottschall will handle the Roller-Smith company's lines of instruments, meters and circuit breakers in the state of Texas with the exception of a small portion in the western part of the state. He has had an extensive experience in the sale and installation of electrical apparatus in his locality and his technical ability and wide acquaintance with the trade place him in an excellent position to handle the company's rather complex lines. The company is also distributing Bulletins No. 73 and 74, describing "Standard" type circuit breakers. The undervoltage, overload and combined overload and under-voltage types are furnished for both alternating and direct current, the underload type being furnish for direct current only.

Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., has issued Circular No. 7375 describing the Westinghouse achievements in field of electrical precipitation. The process applies to copper, lead or zinc smelters, blast furnaces, chemical, acid and cement plants for the recovery of valuable material otherwise wasted. Water can be precipitated from oil, dust removed from ventilating systems, etc. It is also applicable to operations such as round houses which by their smoke or fumes are a nuisance to the surrounding territory. The necessary apparatus for the precipitation process such as motor-generators, transformers, rectifiers, motors, switchboard and accessories are shown installed, and are described in detail in this circular. While there are several mechanical and chemical methods for collecting or suppressing dust in furnace and kiln operation, they are in general limited in application by conditions of temperature, acid, and similar qualities of the product to be handled. Electrical precipitation has few limitations of this sort and is generally applicable for collecting suspended solid and liquid particles of every description, whether acid, alkaline, or from gases of widely varying temperature.

Cutler-Hammer Manufacturing Co., Milwaukee, Wis., has prepared for further publicity on the C-H Seventy Fifty switch eight two-color stickers which will be used on the outgoing mail from the company's home and eight district offices. These will be furnished to dealers, contractors, jobbers and central stations, for use on letters, envelopes, folders, packages and similar material. Four of the stickers have been prepared especially for the jobber and others who do not come in direct contact with the consumers, while the other four are especially for the dealer. They direct the customer to bring their appliances cords to the dealers to have them equipped with C-H Seventy-Fifty switches, thus following the trend of all the national and direct advertising being done on this switch of convenience and safety.

Wallace & Tiernan Co., Inc., New York, has the distinction of having its liquid chlorine apparatus for treating water used in hundreds of cities throughout the United States. It is estimated that the company's apparatus makes 3,000,000,000 gal. of water fit for consumption daily, an amount that to flow over Niagara Falls would require 44½ minutes. The average cost of the chlorination by this system is said to be less than 50 ct. per 1,000,000 gal. The company has recently issued another edition of its booklet, "Protecting the Water Supply of Greater New York." This describes how the W. & T. apparatus was adopted after a competitive test for purifying New York City's water supply, and contains also much general information on the metropolitan problem. Copies of the booklet will be mailed free upon request.

Morse Chain Co., Ithaca, N. Y., is distributing publication No. 14 revised as of June, 1919, illustrating and describing the Morse silent chain and showing a few of the many large power drives of 100 hp. up to 5000 hp. A table of data to be used in the preliminary design of Morse silent-chain drives is included. The bulletin contains full and complete data necessary for filling out the blank inquiry page and securing estimates and details of the Morse chain drive. The application of this chain for transmitting large powers has come to be recognized, not only as good mechanical practice where the specifications favor such a drive, but as highly desirable on account of its great efficiency, quiet operation, low upkeep cost and long life in many places where belts or gears could be used. The marked popularity of the Morse silent chain for the larger powers is not confined to any particular field, but is well distributed over every industry.

Edwards & Johnston, Indianapolis, Ind., is the name of a recently organized firm which will devote its services to investigations, research, engineering, accounting, supervision, management, financing, appraisals and rate cases, of electric light and power plants, gas, water, heating and telephone plants, and electric street, urban and interurban railway properties. C. A. Edwards, senior member of the partnership, was until recently and for nearly six years a member of the Indiana Public Service Commission, and formerly a banker and successful merchant. He will have personal charge of all cases before state commissions and the Interstate Commerce Commission. J. K. Johnston, the other member of the partnership, is a telephone engineer of Indianapolis. Both members of the new organization have made splendid reputations in their lines of endeavor and are especially well known in Indiana and Ohio.

The Electric Furnace Co., Alliance, Ohio, has just installed a battery of two Baily Electric furnaces at the Capital Brass Works, Detroit Mich. These furnaces are the standard 105-kw. tilting type with hearth capacities of 1500 lb. each. They will be used for melting yellow brass scrap and borings in the foundry. The Buick Motor Co., Flint, Mich., has just purchased a second Baily electric furnace for melting phosphor bronze. The furnace is of the tilting type, rated at 1500 lb. hearth capacity, and an electrical capacity of 105 kw. The Akron Bronze & Aluminum Co., Akron, Ohio, has installed a 50-kw. rectangular tilting type Baily electric furnace in its jobbing foundry. This furnace has a hearth capacity of 300 to 500 lb. and will be used for a wide variety of compositions. Heats will range from 100 to 500 lb. and will include gun metal, phosphor bronze, red and yellow brass.

Electric Storage Battery Co., Philadelphia, Pa., is distributing a new publication on the subject of the "Ironclad-Exide" battery as used on industrial trucks and mine locomotives, pointing out their importance and efficiency in the transfer of material. The industrial truck and the mine locomotive are illustrations of modern methods of haulage, and there are few up-to-date manufacturing establishments or mines that could not employ one or more of these units. They do the work of many laborers and speed up the haulage so that not only greater quantities of goods are moved but a large economy in labor is secured. The applications of electrically propelled trucks and tractors, which are found in manufacturing establishments throughout the country and used in railway and wharf haulage and mines, on which the "Ironclad-Exide" battery is extensively used, are shown. Copies of this interesting booklet may be secured from any of the sales offices of the company or by direct request to its general offices at Philadelphia.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Liberty, Me.—Liberty Light & Power Co. has incorporated with a capital of $5000 to generate and distribute electricity for light, heat and power service in Liberty. H. W. Maitherson is president and J. P. Sanford, clerk and treasurer, both of Liberty.

Laconia, N. H.—Scott & Williams have recently broken ground for the construction of the proposed 1-story boiler plant at their works, and favorable progress is being made. The structure is estimated to cost $20,000. Lockwood, Greene & Co., 60 Federal street, Boston, Mass., are engineers for the company.

Woonsocket, R. I.—Barnard Worsted Co., 92 South Main street, has awarded a contract for the construction of a new boiler plant at its works, to be erected in connection with a new dye plant. The work is estimated to cost $14,000.

New Britain, Conn.—Considerable electric equipment, including motors, and other electrical machinery, will be required by the Hart & Hutchinson Co., Corbin avenue, in connection with the construction of a large 1-story plant, about 77 by 340 ft., estimated to cost $65,000, contract for which was recently awarded. The company manufactures steel lockers and kindred equipment.

Brooklyn, N. Y.—Announcement has been made that John H. Delaney, transit construction commissioner, has authorized the New York Consolidated Railroad Co. to contract for the construction of 100 additional steel cars for operation on the subway and elevated lines of the Brooklyn Rapid Transit System. The new rolling stock will cost about $1,628,000, or approximately $12,049 for each car body and $2117 for each motor, deliveries to be made within 14 months.

Brooklyn, N. Y.—A. Arnesen, Inc., operating an electrical contracting establishment at 312 Court street, has filed notice with the Secretary of State of a change in its corporate name to Arnesen Electrical, Inc.

Brooklyn, N. Y.—In connection with the proposed issuance of receivers' certificates for $20,000,000 by the Brooklyn Rapid Transit Co., recently authorized by Federal Judge Mayer, it is understood that a total of $5,000,000 of this issue will be used for improvements in the surface lines of the company's system.

Brooklyn, N. Y.—United States Government, Bureau of Yards & Docks, has awarded a contract to B. Diamond, 12 Bergen street, for the erection of a new extension to the substation at the local naval station.

Geneva, N. Y.—Plans have been arranged by the City Council for the immediate installation of a new electrically operated pumping unit at the municipal water works plant, to have a capacity of 4,000,000 gals. per day. The new unit will replace the two 2,000,000-gal. capacity pumps now in operation at the works. The superintendent of public works is in charge.

Lyons, N. Y.—Empire Gas & Electric Co. has filed with the Public Service Commission, Second District, a new tariff under which it proposes to establish new seasonal service power rates to all consumers within the service area having a connected 5 hp. or over and operating four months or less during the year. The company will require a guarantee of $1.00 per month per horsepower, the rates being as follows: $1.00 per month per horsepower connected, minimum 5 hp., plus 6 cents per kilowatt-hour for the first 120 kilowatt-hours' use of each horsepower connected, plus 3 cents per kilowatt-hour for all current consumed in excess of this amount. It is proposed also to arrange a seasonal charge of 50 cents per kilowatt capacity of transformer installed, to cover the cost of setting and removing transformers.

New York, N. Y.—Announcement has been made by the American Flying Club, 11 East 38th street, that plans are now in process of formation for the establishment of a chain of radio stations across the continent, in order to allow for communication of airplanes at 30-minute intervals.

New York, N. Y.—A resolution has been adopted by the Public Service Commission, Second District, calling for an investigation of the numerous complaints made by business firms as regards inefficient service recently given by the New York Telephone Co. A series of public hearings will be held commencing Aug. 8. It is understood that in connection with the inquiry, the question of rates will also be gone into.

New York, N. Y.—Effective Aug. 1, the New York Railways Co. and the Brooklyn Rapid Transit Co. have placed into operation a charge of two cents for transfers, recently authorized by Public Service Commissioner Nixon.

New York, N. Y.—Interborough Rapid Transit Co., 165 Broadway, has had plans prepared for alterations and improvements in its 1-story car repair plant at 1530-42 Lexington avenue. The work is estimated to cost about $50,000.

New York, N. Y.—New York Edison Co., 130 East 15th street, has awarded a contract for alterations in its 3-story power plant at 123 East 83rd street.

New York, N. Y.—Westinghouse Lamp Co. has recently completed negotiations for the disposal of its group of 5-story factory buildings at 510-32 West 23rd street, held at $400,000. The property is located between 10th and 11th avenues.

Niagara Falls, N. Y.—Niagara Falls Power Co. has filed application with the Public Service Commission for approval of its first and consolidated mortgage, dated July 1, to secure an issue of bonds not exceeding $75,000,000.

Atlantic City, N. J.—In connection with an ordinance recently passed by the City Commission transferring rights of the Atlantic Coast Telephone Co. to the Delaware & Atlantic Telegraph & Telephone Co., and the sale of the former company's property in Atlantic City for a consideration of about $60,000, approval has been granted by the Board of Public Utility Commissioners.

Brunswick, N. J.—Plans have been prepared by Acting Supervising Architect James A. Wetmore, Treasury Department, Washington, D. C., for the installation of new heating equipment, boiler, etc., at the local post-office building.

Hackensack, N. J.—Hackensack Water Co. has been granted permission by the Board of Public Utility Commissioners to place into effect a surcharge of 17.5% applicable to all schedules of rates existing under an order made by the Board in April, 1917.

Lambertville, N. J.—Lambertville Public Service Co. has recently completed plans for the installation of a quantity of new machinery at its local power plant, to facilitate operations. Harold R. Wilbur is manager.

Newark, N. J.—Final contracts have been awarded by the Seton Leather Co. for the construction of the proposed new tannery addition to its plant, with 1-story boiler house, estimated to cost $55,000 and $10,000, respectively. The Essex Construction Co., 87 Academy street, is the contractor.

Newark, N. J.—Krich Light Co., 70 Springfield avenue, has completed negotiations for the purchase of a 5-story brick building at 306 Market street, near Alling street, for a new establishment. The company manufactures electrical fixtures and supplies.

Newark, N. J.—Louis Sacks, operating a foundry on Wilson avenue, near Avenue L, has had plans prepared for the construction of a 1-story brick boiler plant at the works, to facilitate operations. The structure is estimated to cost $5000.

New Hope, N. J.—New Hope Electric Light Co. is understood to be considering plans for alterations and improvements and the installation of a quantity of new equipment at its power plant to facilitate operations.

Perth Amboy, N. J.—Plans are under consideration by the lighting committee of the Board of Aldermen for the installation of new electric machinery at the municipal light and power plant.

Trenton, N. J.—Board of Public Utility Commissioners has granted permission to the Eastern Telephone & Telegraph Co., operating in Camden, Gloucester and Cape May counties, to increase its rates for service.

Trenton, N. J.—Board of Public Utility Commissioners has authorized the sale of the property of the Vulcan Electric Light & Power Co. to the Cape May Court House Light & Water Co. for a consideration of about $35,072, and the issuance of stock to the amount of $24,200 by the Cape May company.

Allentown, Pa.—Lehigh Electric Co., 15-17 North Sixth street, is making alterations and improvements in its establishment, to increase the present capacity.

Catasauqua, Pa. — Lehigh Valley Light & Power Co. is planning for the immediate installation of new lighting units throughout the municipality.

Crafton, Pa.—Duquesne Light Co., Pittsburgh, has completed arrangements for the erection of a 2-story local substation on Noble street, about 24 by 83 ft., with 1-story rear wing, 42 by 40 ft., estimated to cost $45,000.

Gettysburg, Pa.—Plans are under consideration by the Town Council for the construction of a new electric light plant, to be used for municipal service.

Harrisburg, Pa. — Bell Telephone Co. has completed the removal of its offices from 208 Walnut street to larger quarters at 206 North Third street. W. H. Fetter is manager.

Harrisburg, Pa.—Bell Telephone Co. has been granted permission by the Public Service Commission to file the present rates as those to be effective after the return to private ownership by the Government of the wires, with the stipulation that a hearing should be held on Sept. 17, and notice given by advertisement for three weeks "showing in a general way the amount of such increases."

Harrisburg, Pa.—Governor Sproul of Pennsylvania has recently granted approval to the telephone merger bill passed by the Legislature. The measure provides that subject to approval by the Public Service Commission, corporation accepting the provisions of the act "may buy and own all or any part of the capital stock of any other like corporation, and may acquire, enjoy all the franchises, corporate property, rights, and credits then possessed, owned, held or exercised by said last mentioned vendor corporation" including telephone lines. The bill provides procedures for mergers.

Philadelphia, Pa. — Announcement has recently been made by the Philadelphia Storage Battery Co. of the perfection of a new storage battery guaranteed to perform substantially 100% service for a period of two years instead of 12 months. It is understood that the new battery will be placed on sale during the present month. Edward Davis is president.

DATES AHEAD.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 26-28. Headquarters, Hotel Ottawa. Secretary - treasurer, Herbert Silvester, Monroe, Mich.

Pennsylvania Electric Association Annual convention, Bedford Springs, Pa., Sept. 3-6. Secretary, H. M. Stine, 211 Locust street, Harrisburg.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston Block, Seattle.

Southeastern Section, N. E. L. A Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

American Electrochemical Society Fall meeting, Chicago, Sept. 23-26 Headquarters, Congress Hotel. Secretary, Prof. Joseph W. Richards, Lehigh University, Bethlehem, Pa.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Philadelphia, Pa.—Liggett & Myers Tobacco Co. has completed arrangements for the installation of new boiler equipment at its plant at Third and Ontario streets.

Philadelphia, Pa.—Plans have been completed by the A. Schoenhut Co., Adams and Sepviva streets, for the erection of a boiler plant in connection with the construction of a sawmill to be located at Venango and Amber streets. Ballinger & Perrot, 17th and Arch streets, are architects for the company.

Philadelphia, Pa.—Schimmel Electric Supply Co., 318 Market street, has acquired the building at 232-34 Market street, about 38 by 168 ft., for a new establishment. The property was held at $135,000.

Philadelphia, Pa.—The Bureau of Water is making rapid progress on improvements in the engine and pumping equipment at the Torresdale station, to increase the capacity to about 180,000,000 gals. daily. It is understood that plans are being arranged by the department for the installation of four new pumping units for the Queen Lane station, to increase the capacity from 40,000,000 gals. to from 120,000,000 to 140,000,000 per day. Consideration is also being given to the construction of additions to the filtration plant at this latter station.

Pittsburgh, Pa.—City Council has recently authorized the disposal of the municipal pumping station located in River avenue, in the Northside district, for a consideration of about $125,000.

Reading, Pa.—Philadelphia & Reading Railway has awarded a contract to the Robert E. Lamb Co., 845 North 19th street, Philadelphia, for the construction of a 1-story brick, steel and concrete power plant, about 30 by 50 ft.

Clarksburg, W. Va.—Weston Electric Light, Power & Water Co. is considering plans for the installation of a quantity of new equipment at its plant, including electric motors, to be used for air compressor or blower, for low water centrifugal pumps, etc., new head indicating gauges, and other equipment.

Kenova, W. Va.—Ohio Valley Electric Railway Co. will expend $50,000 in improving plant at Kenova and $75,000 in improvements in Russel, Ky. Address general manager.

Logan, W. Va.—Guyan Machine Shops desire prices on 100-hp., three-phase, 60-cycle, 800 r.p.m., 2300-volt motor with flexible coupling or pulley, and 15-hp. and 20-hp. three-phase, 60-cycle hoist motors.

Piedmont, W. Va.—Plans are under consideration by the Baltimore & Ohio railroad for the complete electrification of its system over the 17-mile grade district, to facilitate operations.

Federalsburg, Md.—Eastern Shore Gas & Electric Co. is making rapid progress on the rebuilding of its line between Federalsburg and East New Market, changing it from a single-phase to a three-phase system, to provide for increased capacity. It is understood that the company is arranging plans for the erection of a new outdoor substation on property recently acquired.

Security, Md.—Breakage, caused by a stroke of lightning on July 28, caused the suspension of operations at the large local power plant, placing out of service the entire Hagerstown & Frederick railway system which supplies power and light throughout western Maryland, northern West Virginia, and the southern part of Franklin county, Pa. An auxiliary local plant was placed into service, and work on repairs is progressing rapidly.

Dover, Del.—Central Power Co., of Chicago, a Delaware incorporation, has filed notice with the Secretary of State of an increase in its capitalization from $1,750,000. to $3,000,000.

Dover, Del.—Keokuk Water Power Lighting Co. Capital, $400,000. To operate electric light and power utilities at Keokuk, Ia. Local incorporators: L. A. Irwin, M. L. Rogers and W. H. Singer.

Wilmington, Del.—Announcement has been made by the Electric Specialty Co., 849 Tatnall street, that a new branch establishment will be inaugurated at 827 Market street.

Bakersville, N. C.—Bakersville Milling, Light & Power Co. is considering plans for the erection of an electric plant, estimated to cost $10,000. R. T. Teague is manager.

Charlotte, N. C.—Southern Power Co. is understood to be considering plans for the construction of a new electric substation at Marshville to furnish electric power to the city, which has recently voted the issuance of bonds for $300,000, for the construction of a municipal electric system.

Hayesville, N. C.—Public Service Co. has incorporated with a capital of $125,000; incorporators are G. H. Haigler, W. J. Winchester and others. Purchased and will enlarge electric plant, develop water power on Shooting Creek, and other streams, supply city with electricity, also drill well for water supply, erect flour mill, ice and cold-storage, creamery, etc.

Gaffney, S. C.—Plans are under consideration by the Board of Public Works for the installation of a street-lighting system of the "white way" type.

Elberton, Ga.—An election will be held Aug. 27 to vote on $15,000 bonds for the extension of the light, water and sewer systems. Address the mayor.

NORTH CENTRAL STATES.

Columbus, O.—Increases in the demand for electric current from the municipal light plant will necessitate improvements and additional equipment which will cost $39,497 and to take care of these demands Superintendent Lewis Rowe has recommended to Service Director Geo. A. Borden that council authorize a bond issue of $40,000.

New Concord, O.—Bonds to the amount of $35,000 have been voted to purchase a water works and electric light plant.

Chicago, Ill.—Byllesby Engineering & Management Co. has been incorporated under Delaware laws with a capital of $10,000,000 as an affiliated organization to H. M. Byllesby & Co., Inc., Chicago.

Marquette, Mich.—Architect Thos. W. Orbison, Appleton, Wis., has prepared plans for $150,000 light and power plant to be erected by City Commission of Marquette; the building will be brick and steel, reinforced-concrete construction, including steam heating, plumbing, brick interior finish. The specifications include electrical equipment. Contracts will be let by city clerk.

South Haven, Mich. — The City Council is planning ways and means to secure additional electric power. Address city clerk.

Atlantic, Ia. — Architects D. S. Fisher & Co., Davenport, have prepared plans and will let contracts for $26,000 power plant addition to be erected by the city. The building will be brick construction, 15 by 18 ft. in dimensions, including steam heating, plumbing, fireproof interior finish. Generators, pumps, motors, etc., will be purchased for electric lighting. Address city clerk, Atlantic.

Stout, Ia.—A meeting was held to organize a company for the purpose of building an electric line from Dike to Stout and from Stout to Fern. Address village clerk.

Storm Lake, Ia.—On Aug. 11 the citizens will vote on a proposition to issue $100,000 in bonds for the erection of a municipal electric light, heat and power plant. It is believed the proposition will be carried.

Terrill, Ia.—On Aug. 18 the people of Terrill will hold a special election for the purpose of voting on the proposition of issuing $6000 in bonds for electric lights and the granting of a franchise to Charles Larson, of Spencer, to furnish power for the town.

Traer, Ia.—Municipal light bonds for $50,000 have been authorized.

Wapello, Ia.—Bids will soon be advertised for the installation of a new pumping plant in the lower end of the No. 13 drainage district. Charles Young, engineer.

Kirksville, Mo.—The local light and power plant was damaged by fire; loss $15,000.

SOUTH CENTRAL STATES.

Frankfort, Ky.—Kentucky & West Virginia Power Co., recently incorporated with a capital of $6,000,000, has acquired the system of the Kentucky River Power Co. at Hazard, aggregating in value about $1,000,000; the $1,000,000 plant of the Rug River Electric Co. at Sprigg, W. Va., and the power station of the Logan County Light & Power Co. at Logan, W. Va., valued at $500,000. It is understood that additional power properties will also be developed by the new organization. R. E. Breed, president of the American Gas & Electric Co., Philadelphia, Pa., is interested in the company.

Louisville, Ky.—Wm. C. Krauth Electrical Co., 113 West Market street, will construct brick addition and install machinery. Wm. C Krauth, president.

Owensboro, Ky.—Kentucky Electric Lamp Co. has awarded a contract for the construction of a 3-story brick and concrete plant, about 60 by 200 ft., for the manufacture of electric lamps. The structure is estimated to cost $20,000. It is proposed to increase the present capacity of the company from 3000 to 8850 lamps daily. Ray Burlew is secretary.

Wolfpitt, Ky.—McKinney Steel Co. will expend $60,000 in building power house for which considerable electric equipment will be purchased. Address general manager.

Centerville, Tenn.—City Council is arranging plans for the construction of a new municipal electric light plant. Bonds to the amount of $15,000 have been voted to cover the cost of the proposed work.

Knoxville, Tenn.—The Knoxville Gas Co. will remodel plant, for which $12,000 will be expended. The remodeling and installation of new machinery will be started at once and the work will be completed in about six weeks.

Nashville, Tenn.—Plans are being arranged by the City Council for extensive improvements and alterations in the municipal electric light plant. The work is estimated to cost $48,000.

Birmingham, Ala.—In connection with the recent issue of notes for $6,000,000, the Sloss-Sheffield Steel Co. set aside an appropriation of $1,250,000 for the electrifying of its mines in the Birmingham coal and iron district.

DeRidder, La.—City officials planning for the issuance of bonds of $100,000 to provide for the installation of a municipal electric light system and waterworks plant.

Frederick, Okla.—City will install lamps; $40,000 bonds. Address mayor.

Bryan, Tex.—The City Commission has ordered an election here for Aug. 26 to vote on issuing $75,000 bonds, the proceeds to be used in purchasing the electric light and power plant from H. T. Lawler & Sons. If the plant is purchased it will be enlarged and otherwise improved.

Dallas, Tex.—Dallas Power & Light Co. has increased its capital stock from $1,000,000 to $2,500,000. It plans important extensions to its power transmission system.

Dallas, Tex.—It is stated by J. F. Strickland, president of the Texas Electric Railway Co. and the Dallas Railway Co., that the interests which he represents will begin the construction of an interurban electric railway out of Dallas on or before Nov. 1. In an agreement entered into between the Texas Electric Railway Co. and the City Commission it is provided that the line shall be completed within 18 months from the time the work is started and that the road must be at least 30 miles in length. Mr. Strickland said that the proposed road may be built either to Terrell, Greenville or Denton. This is the first of three interurban lines arranged for when the street-railway franchises in Dallas were granted.

Fort Worth, Tex.—The local telephone company is engaged in the installation of additional facilities for the purpose of improving the local and long-distance service that will require the expenditure of about $50,000. The improvements will include underground cable extensions, the installation of switchboards, etc.

Houston, Tex.—Houston Light & Power Co. will install a 10,000-hp. turbine-generator and extend its transmission system.

WESTERN STATES.

Grand Junction, Colo.—A movement has been started at Collbran for the installation of a hydroelectric plant to supply light and power to practically every section of the Plateau Valley.

Boise, Ida.—Idaho Power Co. plans erecting a transmission line to connect its eastern and western systems in southern Idaho, and it is proposed to build a line from Shoshone Falls to American Falls to connect at the latter place with the Utah Power & Light Co.'s system. The Idaho company has completed a 4000-hp. unit at lower Salmon Falls, south of Twin Falls, and it is now proposed to build a 6000-hp. hydroelectric plant at Thousand Springs on Snake river, to reinforce its system of power production.

Ogden, Utah.—An electric line may be built from Ogden, along 21st street, to the district west of the city. John S. Lewis is president of the company.

Bellingham, Wash.—At a meeting of the Kullshan Civic Improvement Club plans for extending the electric light line to the vicinity of Lake Padden were discussed.

Portland, Ore.—Construction of a $3,000,000 radio station to be located at the mouth of the Columbia river is being considered by the Federal Government.

Scofield, Ore.—A large mill is being built on the ground where fire recently destroyed 5,000,000 ft. of lumber, the sawmill, planing mill, power house and electric lighting plant. The Standard Lumber Co. is owner.

Santa Monica, Cal.—The arc lamp lighting throughout the Palisades section of the city is to be replaced soon by ornamental post lights in many of the streets. Specifications are at the office of the superintendent of public works.

Oakdale, Cal.—Calaveras Copper Co. has in preparation plans for a reservoir and power plant to supply electricity to the plant at its mines in Copperopolis.

MEXICO.

Monterey, Mexico.—According to announcement made by the Department of Communications and Public Works of the Mexican government, it has just entered into a contract with the Mexican Tramways Co., Ltd., for the resumption of construction of the interurban electric line that is to run between the City of Mexico and Puebla, about 130 miles. The construction of this line was started about 12 years ago but before much progress had been made the revolutionary activities caused a suspension of the work. Later the lines of the company were taken over by the Mexican government, and, if they have been turned back to their owners, it is only recently that this was done. The company is composed of Canadian and English banking interests and was headed by the late Dr. F. S. Pearson of New York, who lost his life in the sinking of the *Lusitania*. The same interests own the great hydroelectric plant at Necaxa which generates about 100,000 hp. of electricity. This power is transmitted to the City of Mexico, 96 miles, to El Oro, 54 miles, and to other points. The proposed interurban electric line to Puebla will traverse a route that passes close to the foot of Mt. Popocatepetl and Ixtaccihuatl volcanoes.

Tampico, Mexico.—The Mexican government has granted a concession to the National Norwegian Co. for the construction of an interurban electric railway between Tampico and Tuxpam, about 120 miles, with branch lines to several smaller towns in the oil-producing territory. The route of the proposed main line will closely follow the Tampico-Tuxpam intercoastal canal. The National Norwegian Co. is composed of large banking interests of Copenhagen. It was organized under the laws of Mexico only a few months ago for the purpose of operating in the oil fields of the Gulf Coast region. From the very beginning it met with marked success in developing large production of crude petroleum. It has established its principal office in Tampico.

PROPOSALS

Cable.—Bids will be received by the commissioner of gas and electricity at his office, Room 614, City Hall, Chicago, Aug. 11, for furnishing and delivering to the city of Chicago, in accordance with specifications on file in the office of the commissioner and in the following approximate quantities: No. 19 B. & S. gauge paper-insulated, lead-covered, fire-alarm cable; 79,200 ft. of 15-pair, 72,800 ft. of 30-pair, No. 16 B. & S. gauge rubber-insulated, lead-covered, fire-alarm cable; 5000 ft. two-conductor and 5000 ft. four-conductor cable. Address William G. Keith, commissioner of gas and electricity.

Copper Wire.—The Department of Purchases and Supplies, New Municipal Courts building, Detroit, Mich., will receive bids until 10:30 a. m., Aug. 14, for furnishing the Board of Fire Commissioners with 50 miles of No. 10 B. & S. gauge, triple-braid weatherproof hard-drawn copper wire.

Electric Work.—Until 7:30 p. m., Aug. 12, bids will be received by Arthur Davenport, secretary of Dorranceton Borough, Wilkes-Barre, Pa., for the erection of a town hall and installation of heating, plumbing and electric work. E. E. Joralemon, architect, 547 Franklin street, Buffalo, N. Y.

Electric Work.—Until 3:15 p. m., Aug. 16, bids will be received by the Board of Education, Sussacunna, N. J., for general construction, plumbing, and electric work for the proposed alteration and additions to Port Morris school building. Rasmussen & Wayland, architects, 1133 Broadway, New York City.

Power Transmission Lines.—The Hackensack Improvement Commission, Hackensack, N. J., will receive bids until 8 p. m., Aug. 18, for construction and equipment of disposal works, flotation basins, power house, power transmission lines, air lines, ejectors, etc. Lemuel Lozier, engineer of commission, Room 3, Bank building, Main and Mercer streets.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number given.]

Motors (30,106).—A man from Finland who is in this country for a short time desires to purchase shoes, raw hide, sole leather, leather goods, concrete-mixing and other building machinery, and gasoline and electric motors. Reference.

INCORPORATIONS

Wilmington, Del.—American Conduit Manufacturing Corp. has incorporated with a capital of $540,000, to manufacture electrical conduits, etc. Incorporators: C. L. Rimlinger, P. D. Drew, and H. E. Knox, Wilmington.

Belleview, Fla.—Belleview Utilities Co. has incorporated with a capital of $25,000, to operate a local light and power plant. Incorporators: F. E. Martin, president; John L. Carney, vice-president; and Edward S. French, secretary-treasurer.

Hartford, Conn.—Perry Electric Co. has incorporated with a capital stock of $20,000. George W. Perry, Ernest C. Perry and S. J. Perry are incorporators.

Boone, Ia.—Napioer Electric Co. has incorporated with a capital stock of $10,000. S. A. Walker is president and W. A. Gillette is secretary.

Hazard, Ky.—Kentucky & West Virginia Power Co. has incorporated with a capital of $6,000,000. The incorporators are Bailey P. Wooten, H. T. Taylor and J. G. Green.

Montclair, N. J.—Filtration Engineers, Inc., has incorporated with a capital of $80,000, to manufacture engines, etc. Incorporators: F. W. Young, Verona; G. H. Caffey, Brooklyn, N. Y., and H. E. Kinner, Yonkers.

New York, N. Y.—Alpha Laboratories has incorporated with a capital of $60,000, to manufacture incandescent lamps, etc. Incorporators: J. H. Mandidge, W. A. Bell, and W. T. Davis, Ogdensburg.

New York, N. Y.—Emzee Electrical Conduit & Manufacturing Co. has incorporated with a capital of $5000, to manufacture conduits and kindred equipment. Incorporators: M. E. Meredith, T. Ganer, and P. Simon.

New York, N. Y.—Motorite Corp. has incorporated with a capital of $100,000, to manufacture motors, machinery, etc. Incorporators: C. E. Taoru, S. A. H. Dayton, and M. F. Mills, 211 West 82d street.

New York, N. Y.—Paragon Incandescent Lamp Works has incorporated with a capital of $60,000, to manufacture electric lamps, etc. Incorporators: F. Alexander, N. Favian, and L. T. Levy, 110 Morningside drive.

Asheboro, N. C.—Electric Equipment Co. has incorporated with a capital of $5000 by Leo Barker, Carl Kivett, of Asheboro, and H. T. Long, of Charlotte.

Bakersville, N. C.—Bakersville Milling, Light & Power Co. has incorporated with a capital of $25,000. J. C. McBee is one of the incorporators.

Dalmatia, Pa.—Dalmatia Light Co. has incorporated with a nominal capital of $5000 to operate a local plant. F. Brosious is the principal incorporator.

Nashville, Tenn.—Gibson Light & Power Co. has incorporated with a capital of $6000. E. H. Lessenberry is the principal incorporator.

Personal

H. D. Larrabee Becomes General Manager of Eastern Connecticut Power Company—Promotions and Other Changes

EARLE W. VINNEDGE, who recently was released from military service, has joined the staff of the Worthington Pump & Machinery Co., Cincinnati office, in the capacity of sales engineer.

H. F. CAMERON, of the Lake Charles Railway, Light & Power Co., has been appointed vice-president and general manager of the Texas Gas & Electric Co., and will have his headquarters in Houston, Tex.

L. A. WALLON recently returned to Seattle from Chicago, where he was drafted by Stone & Webster on the indexing system for the appraisal of the Chicago surface lines, and is again on his job as assistant engineer of the Puget Sound Traction Light & Power Co. at Seattle.

FRED BATES JOHNSON, Indianapolis, Ind., has been named a member of the Indiana Public Service Commission by Governor Goodrich. Mr. Johnson was formerly a newspaper man and served for a time in the army. He succeeds Charles A. Edwards of Huntington.

ORVILLE R. TOMAN is again with the Continental Gas & Electric Corp., Omaha, Nebr., as superintendent of construction of overhead lines and substations. Mr. Toman served two years with the Signal Corps and was in France with the 109th Signal Battalion, specializing in radiotelegraphy and radiotelephony.

J. F. OWENS, vice-president and general manager of the Oklahoma Gas & Electric Co., has been made president of the new War Camp Community Club, which has just been organized in Oklahoma City. The organization is for the purpose of providing entertainment, suitable welcomes and employment for returned soldiers.

A. W. HOUSTON has resigned his position as vice-president and general manager of the Texas Gas & Electric Co., to accept a similar position with the Southern Utilities Co. Mr. Houston will have his headquarters in Palatka, Fla., and will have supervision of plants of the Southern Utilities Co. in the states of Florida and Georgia.

G. E. CARLSON, formerly of the F. E. Newbery Electric Co., Chicago, has been appointed manager of the Chicago office of the Hatfield Electric Co., electrical contractors and engineers, located in the Insurance Exchange building, 175 West Jackson boulevard. Mr. Carlson has had a very broad experience in electrical work and is well known in the electrical contracting fraternity.

MATTHEW S. SLOAN, operating manager of the New York Edison Co., New York, was recently elected president of the Brooklyn Edison Co., to succeed N. F. Brady, resigned. Mr. Brady will continue as chairman of the Board of Directors and the Executive Committee. Mr. Sloan was for a period of 4 years vice-president and general manager of the New Orleans Railway & Light Co.

F. N. COOLEY has been promoted from assistant sales manager to sales manager of the Seattle office of the Western Electric Co. Mr. Cooley first became associated with the company in 1912 as lamp salesman at San Francisco. Two years later he became supply specialist at Seattle, a little later becoming assistant manager there.

WILLIAM A. BAEHR, a well-known consulting engineer of Chicago, through the purchase of the Southern Illinois Light & Power Co., Hillsboro, Ill., has been elected president of that company. Mr. Baehr takes up the duties of J. J. Frey, of St. Louis, formerly president of the company. Mr. Frey, however, is retained as vice-president and a member of the Board of Directors.

ARTHUR G. GEHRIG, structural engineer, Western Electric Co., Chicago, has been appointed associate professor in civil engineering, in charge of structural engineering at the University of Nebraska. He has been previously employed by the American Bridge Co. on erection work, including the Municipal Bridge at St. Louis, and the Balboa shops, emergency dams and Navy coaling stations at the Panama canal.

THOMAS O. MORGAN, until recently head of the service department of the New York office of the American Steam Conveyor Corp., has been promoted to the position of sales engineer. He will handle Long Island and Connecticut territory. Mr. Morgan's sound experience in service work has been a splendid training for his new responsibilities and his customers are assured of receiving authoritative advice on correct ash-disposal engineering.

CHARLES S. RUFFNER, vice-president of the Union Electric Light & Power Co., St. Louis, Mo., has been elected a vice-president of the North American Co., which owns the Union company and whose common stock ownership in the United Railways is controlled by that company. Mr. Ruffner recently relinquished a part of his duties in the management of the Union company to Louis H. Egan, who has been made a vice-president, and has removed to New York where he will reside.

HAROLD D. LARRABEE has been appointed general manager of the Eastern Connecticut Power Co., with headquarters at Norwich, Conn. He is well known in the New England public utility field. He was graduated from the Massachusetts Institute of Technology in 1902 and for the last 10 years has been general manager of the Barre & Montpelier Light & Power Co., of Vermont, one of the properties under the management of Charles H. Tenney & Co., of Boston. The Barre & Montpelier Traction Co. was also under Mr. Larrabee's management during his term of service in the Green Mountain State. At Norwich Mr. Larrabee will have general charge of a 22,000-kw. generating plant interconnected by transmission tie line with the system of the New England Power Co., and supplying the principal municipalities of southeastern Connecticut with electrical energy.

W. GORDON COPELAND has resigned from his position as acting chief inspector of the Commonwealth Edison Co., Chicago, to become associated with Wm. A. Baehr, consulting engineers, 122 South Michigan avenue, Chicago. Mr. Copeland entered the Construction Department of the Commonwealth Edison Co. in 1910 but was soon transferred to the Distribution Engineering Department, in which department he worked in various capacities until 1917. At that time he entered the Coast Artillery of the Army and served as a 1st lieutenant until the close of the war, being on active duty in France at that time. On his return to the Edison company he was made acting chief inspector in the place of Capt. Arthur P. Good, who is still in Government service. Mr. Copeland is a graduate of Cornell University and has made a host of friends in the industry in Chicago.

ARTHUR B. REYNDERS, who since March, 1912, has served as director of production for the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., is now works manager of the East Springfield works. Mr. Reynders was graduated from the University of Tennessee as a civil engineer in 1895 and as an electrical engineer the following year. In June, 1899, he was first employed by the Westinghouse company as a draftsman on switchboards and switchboard apparatus. Three years later he became engineer on circuit breakers, switches and relays and in 1904 was appointed acting assistant chief draftsman. In February, 1906, Mr. Reynders was appointed general engineer on insulator work, and in November, 1909, became assistant to manager of engineering. In March, 1912, he became director of production. The East Springfield works will manufacture small power motors and automobile starting, lighting and ignition equipment. Mr. Reynders is now supervising the installation of machinery.

Electrically Operated Dredge Owned and Operated by City of Oakland, Cal.

Features of Electrically Operated Hydraulic Dredge

Description of Dredge Owned and Operated by City of Oakland, Cal.—Advantages of Electric Drive and Savings Effected — Central-Station Service Is Used

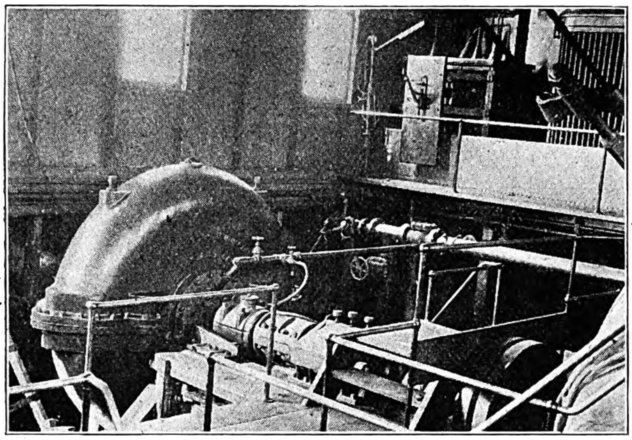
By CHARLES W. GEIGER

ALTHOUGH not an entirely new field for electrical engineering or the application of electric apparatus, there are only a very few motor-operated hydraulic suction dredges in existence at the present time. For this reason a description of the 20-in. dredge, owned and operated by the City of Oakland, Cal., and the successful results obtained are worthy of mention and consideration by the electrical industry.

The operation of a hydraulic suction dredge is a simple process whereby solid material, heavier than water, such as sand and gravel, is raised and transported from its place through pipes by virtue of the velocity of a current of water in the pipes. The dredge itself is similar to a houseboat in appearance and floats on the water. For this reason it is essential that the dredging machinery be as light and compact as possible while from the nature of the work it must be very powerful, rugged and able to withstand heavy overloads and severe usage.

The electric motor affords a compact, easily controlled and highly efficient substitute for steam drive in such work. In addition it permits the use of an exterior source of power which effects a great reduction in the weight of the dredge. Central-station service is of course especially valuable for such work due to the fact that it is often carried on over a large area and on account of the nature of the load. Moreover, such service is much cheaper in the majority of cases. In this particular case a saving of approximately 50% has been effected in several instances and naturally the city officials of Oakland recommend such service and the electrically operated dredge very highly.

The equipment of a hydraulic suction dredge consists of a centrifugal suction pump, the spuds, the



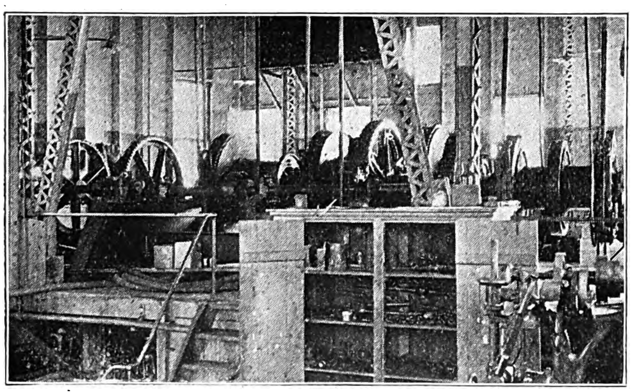
Interior of Oakland Dredge, Showing Pumps and Power Transformers.

cutter and several auxiliaries. On this dredge all this apparatus is operated by electric motors.

The cutting machinery is driven by a 150-hp. variable-speed motor. The motor is operated at 600 r.p.m. and is located in the hold of the dredge forward, on the fore and aft center line, and connected with the cutter by double reduction gearing and a universal coupling. The cutter shaft is operated at 15 r.p.m. and the normal position in operation is at an angle of 45°. The control consists of a reversible drum controller with suitable starting resistance.

For raising and lowering the spuds, cutter head and head lines, a five drum winch is used, belt connected to a 600 r.p.m. variable-speed motor, controlled by a reversible drum controller with a rheostat of sufficient resistance to permit of a 75% speed reduction.

The spuds, which are two heavily weighted iron-shod timbers 65 ft. in length, are at the stern of the dredge and are supported by a steel gallows 60 ft. in height. They serve to brace the dredge as the cutter moves forward into the bed of the stream and can be raised or lowered alternately by a controlling winch, which permits the dredge to swing in an arc. The cutter can be used to open up a channel about 180 ft. in width and cut away the bed of the stream to a depth of 30 to 40 ft. The main suction pipe, which extends along a steel ladder at end of which is the cutter, catches and conveys the dirt and water directly behind the cutter, drawing both off as it is cut away. The suction pump is of the centrifugal type, with a single runner 20-in. suction and discharge operating at 360 r.p.m. It is located athwartships and connected directly by a leather link coupling to a 750-hp., 3-phase, 60-cycle, 2-speed induction motor. Although rated at 750 hp., this motor is able to withstand heavy overloads and often operates at 900 hp. without trouble. The control apparatus consists of a drum controller and an iron-grid heavy-duty starting rheostat, which handles the secondary current of the motor only, the primary current being controlled by means of an automatic oil switch.

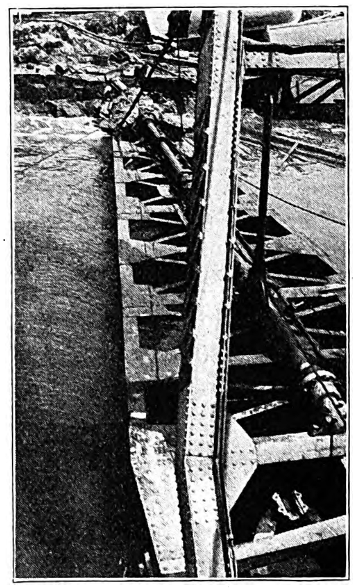


Five-Drum Winch Used for Operating Spuds, Cutter Head and Headlines.

The water and silt from the cutter are carried back over the stern of the dredge through a 20-in. pipe line connection at the rate of 3500 cu. yd. per 24 hrs. With 15% solid material, a velocity of 12 ft. per sec. is obtainable but will vary somewhat according to the class of material handled.

The long continuous discharge pipe is made up of sections 40 ft. in length carried on pontoons and connected by flexible rubber couplings, which serve to carry the material suspended in the water to the desired point of deposit. This pipe line extends to the shore line, and in one particular case had to be submerged in the estuary, so as not to block navigation, and continued to the tide lands of Alameda which were being filled in.

In addition to the above there is one 20-hp., 2200-volt, constant-speed motor belted to a rotary air pump



Cutter Head of Oakland Dredge.

for priming the main suction pump and a 6-in. single-stage centrifugal general service pump.

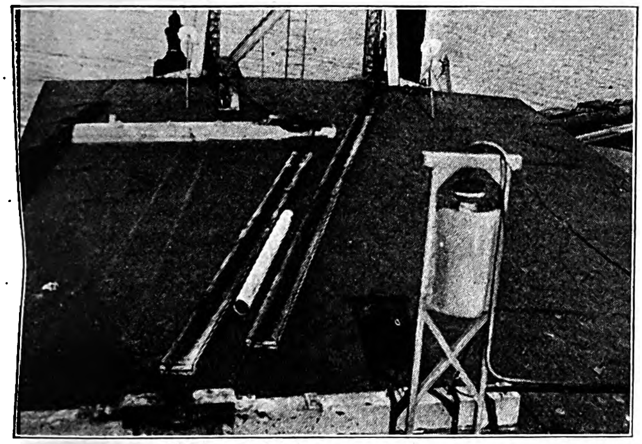
The switchboard consists of one main service panel and three feeder panels. The starting compensators for the constant-speed motors are placed in the stern of the dredge. Power is supplied by the Pacific Gas & Electric Co. over a short transmission line from its station A, in the immediate vicinity at a tension of 11,000 volts stepped down to 2300 volts by means of three 250-kv-a. transformers located on board the stern end of the dredge above the main deck. In addition, a 10-kw. transformer is provided to furnish a 110-volt supply for the lighting of the dredge and the floodlights. Shore connections are made by a 1200-ft., 3-conductor flexible armored cable which permits of considerable range of operation without shifting. The cable is carried on a special reel on a houseboat in the rear of the dredger and is run from the shore to the houseboat on poles placed 200 ft. apart.

Due to the fact that the dredge is usually operated about 20 hrs. a day, special attention has been given to the lighting. The interior of the dredge is adequately lighted with 100 and 150-watt units and in addition several floodlights have been installed on the decks to illuminate the surrounding water surface and the shore. Several of these floodlights are of special construction and all are portable.

Saving Made in Filling in Oakland Auditorium Site.

An illustration of some of this particular dredge's work was the discharge of material through 7500 ft. of pipe line to fill the site where the Oakland Civic Auditorium now stands and which was once a marsh. The average cost of operation of the dredge at the time of making this fill was about $5500 per month. This cost was made up of the following items; labor, $3000, power $2000, incidentals $50. The dredge was operated on an average of 20 hrs. per day and 20 days per month. The work was done at a cost of about 5 cents per cu. yd. The competitive bids made by outside dredging companies, all of whom used steam power, ran from 10½ to 12 cents per cu. yd.

The cost of operating the electric dredge at the present time under average conditions for a long period is about $10,000 per month. This includes



Flood Lights on Oakland Dredge. Light in Foreground is of Special Design.

$950 per month for the motor-boat tender, pipe worn out, and repairs to the equipment. At the present time the dredge averages 20 hrs. of operation every day the year around. The cost per unit fluctuates from 5 cents in mud to 12 cents per cu. yd. for hard pan. According to the Oakland harbor engineer, this dredger is doing work under unfavorable conditions at half the cost of the steam dredgers operated by private contractors. Under the same conditions these contractors would charge from 18 to 24 cents for the work which the city dredger is now doing.

The crew consists of the chief engineer, leverman and eight men on board. Two or three additional men attend to the extending of the pipe on land. This also represents a saving over the number of men required to operate a steam dredge.

ITALY TO ESTABLISH INDUSTRIAL LABORATORIES.

Experiment Stations and Laboratory Schools for Various Industries, Including Electrotechnical, to Be Established.

Appreciating the importance of applying scientific methods in its industrial development, if it is to solve successfully the great problems of reconstruction and to meet competition from other nations whose industries are more highly organized, Italy has decided to devote special attention to the question of industrial experiment stations and of technical education. The necessity for such action is made more urgent by the adoption, in many industries, of an 8-hour day. If the working day is shortened to 8 hours, increased efficiency in manufacturing methods must be brought about if production is to be maintained.

In this connection the Italian Government, together with the manufacturers, is preparing to establish experiment stations for the principal lines of industry. In addition to studying new processes and making new applications of old methods, these stations will supply the industries with a trained personnel. Preparatory meetings at which the manufacturers were represented have recently been held at the office of the Undersecretary of Labor.

Up to the present there have been only four such stations—two at Milan, for paper and fats, respectively, and two at Naples, for leather and ceramics. Another is being added to Reggio Calabria for essential oils and perfumes. At the recent conferences it was decided to establish the following new stations: At Rovigno, for the sugar industry, in connection with the existing school of beet culture; at Milan, for the development of the refrigerating industry; a third, probably at Rome to study the distillation of gases and their byproducts and, in general, all the processes of combustion. One section of this last-named station will devote itself to the question of the utilization of national fuels and lignite, which, it is said, is suitable for the production of gas. Later on consideration will be given to the creation of stations, on the initiative of the manufacturers, for the electrotechnical and phototechnical industries and for dyestuffs.

By a decree of December, 1918, provision was made for the establishment of laboratory schools in order that the standard of vocational education might be raised. At first there will be 20 of these schools, of which two will be at Milan, one for mechanics and the other for carpenters. In addition to a Government subsidy of 25,000 lire ($4825 at normal exchange) each, the laboratory schools will receive appropriations from the local authorities and the obligatory support of the manufacturers. In accordance with an agreement recently reached by the Undersecretaries of Labor and of Arms and Munitions there will be assigned to these schools war material amounting to about 25,000,000 lire ($4,825,000). The schools established by the Ministry of War during the war at Turin, Milan, Genoa, Modena, Florence, Rome, Naples, and Palermo will be transformed into laboratory schools. Provision will also be made for the ordinary industrial schools, 150 of which are royal schools and 400 of which are subsidized. In all these schools short courses of study, both practical and theoretical, will be instituted.

ELECTRIC POWER USED IN BURMAH OIL FIELDS.

Drilling and pumping wells by electric power has been introduced by the Burmah Oil Co. in its operations in the Yenangyoung field in Burmah. Considerable saving in the cost of getting the petroleum to the refineries is one of the chief advantages of the plan, as reported by John T. Cargill, chairman of the board of the company.

Central-Station Rates in Theory and Practice

Sixth Article—How Diversity of Demand Affects the Demand Cost — Diversity-Factor Defined — Other Features Affecting Demand Cost — Mean and Weighted Averages

By H. E. EISENMENGER

This is the sixth article of this series, which will continue to appear weekly throughout practically the entire current volume. A general outline of the entire series will be found in the issue of July 5, 1919. In the early articles of the series, the first of which appeared July 12, costs of service were discussed in general and with special reference to electric service. It was shown that analysis of the costs of rendering this service is necessary before rates for the service can be set or even intelligently discussed. The present article concludes the consideration of the second element of cost—demand cost—and the next one will take up the third element—consumer cost.

PART I—THE COST OF ELECTRIC SERVICE—Continued.

II-A. The Three Elements of Cost.

B. APPORTIONMENT OF THE DEMAND COST BETWEEN THE CUSTOMERS.

5. *The Diversity-Factor.*

SECTION 42. If the load curves of all customers would have the same shape amongst each other, the central station would have to have a load curve of the same shape (disregarding losses and home consumption of the central station) and the peak load of each customer would occur at the time of the central station's peak load. Then the sum of the customers' peak loads would be equal to the central station's peak load and the error introduced by replacing the peak responsibility with the consumer's maximum demand would be nil.

Actually, however, the shapes of the various consumers' load curves are different from one another. We can now classify the consumers into various groups or classes in such a manner that the curves within each class are liable to have similar shapes. For instance, we might group the lighting customers in one class and the power customers in another one. Lighting consumers will draw almost all their current during the evening, whereas most power consumers will consume practically all their current during the regular working hours, that is, mostly in daytime during week days. Then we may subdivide each one of these classes. For instance, the lighting consumers might be subdivided into stores, offices, factories, restaurants, theaters, churches, residences, street lighting and others. If necessary the subdivision may be carried further, for instance, the stores may be subdivided according to what is sold therein, etc. Various central stations have different practices in this respect. Likewise, the power consumers may be divided into a number of classes.

The error will then not be so very great that is introduced by the assumption that all the customers of the same class have the same shape of load curve. Gross deviations from the average load curve will occur only in individual cases and need not be given individual attention. In fact, they cannot be given individual attention.

It is not difficult to picture to ourself how the peaks of various classes occur at various times. The stores will, for instance, have their peak-load time of the year at 5 p. m. or soon afterwards, around Christmas time when the days are shortest. Shortly after that hour the rush hours for the street railway will set in when the people are returning from work to their homes. When they arrive at home their residences will be lit up and we have a peak of the residence load which may last until 9 or 10 o'clock. The theaters will have their peaks beginning at about 8 p. m. The peak of summer amusement parks comes, of course, in the summer evenings after sunset. Similar diversities occur between the peaks of the various classes of power load. Where we have an irrigation load for agricultural purposes the peak of that load will even come in the daytime of summer.

43. We might now from actual measurements in a number of representative cases, or by guesswork, obtain the load curve of every class or group of customers and from this we can obtain the ratio of the group's peak responsibility to the group's maximum demand. Then we would have to multiply by that ratio the known cost per kilowatt of peak responsibility to get the cost per kilowatt of that group's maximum demand. This first step would be only another way of basing the demand cost of the class or group on the peak responsibility of the group. Suppose, for instance, the group's load curve shows a peak four times the amount of its peak responsibility, then the cost per kilowatt demand of the group's peak load would be one-fourth of the cost per kilowatt of peak responsibility. If it costs, let us say, $4 of fixed charges per month to keep 1 kilowatt in readiness at the central station, then we must figure only $1 per month as fixed cost per kilowatt of maximum demand of that class of customers. Since the group's maximum demand can, of course, never be smaller than the group's peak responsibility, this correction to the kilowatt cost of the group's maximum demand will never be an increase of unit demand cost, but generally a reduction.

44. This fact, that the peaks of various classes or groups of consumers do not occur at the same time, is called *diversity* of these classes. To make it quite clear what this means we can look at it in another

way. Taking a simple case, let us suppose we have two classes of consumers only, *A* and *B*, each using 1000 kw. throughout the day, but raising their respective demand to 3000 kw. each for one hour during the day. Now, if these two peaks of 3000 kw. coincide, we would need a plant with a capacity of 6000 kw. to satisfy the aggregate demand. If, however, the peaks occur one after the other a plant of 4000 kw. will be large enough; 1000 kw. for one class and 3000 for the other. We can use a portion of the capacity of the plant twice, so to speak, first for *A* and then for *B* (or vice versa) on account of the diversity which exists between the two demands. If we had *A* alone, that class would have to be charged with the demand cost of 3000 kw. as the plant would have to have the capacity of 3000 kw. and the same would apply if we had *B* alone. As it is, with both classes on the lines and with the diversity between them as stated, we have to provide 4000 kw. for the two, and each one will be charged as an average with the demand cost of 2000 kw. only[1], because, as explained above, on account of the diversity we are able to use a part of the capacity of the first plant for one class of consumers and then for the other one.

45. The degree of diversity is measured by the so-called *diversity-factor,* that is, the ratio of the sum of the maximum demands of the various classes divided by the sum of their peak responsibilities; in other words, the diversity-factor is the weighted average[2] of the ratios $\frac{\text{maximum demand}}{\text{peak responsibility}}$ the meaning of which ratios (or, to be exact, of their reciprocate) has been explained in Section 43. As the sum of the peak responsibilities is equal to the peak load, we arrive at the definition of the diversity-factor as being the ratio of the sum of the maximum demands to the peak load[3]. In our example the sum of the maximum demands is $3000 + 3000 = 6000$ kw. and the actual demand (or the sum of the peak responsibilities) is 4000 kw., so that the diversity-factor is $6000/4000 = 1.5$. Obviously the diversity-factor can never be smaller than unity.

The diversity-factor is of great importance in central-station economics. It indicates, so to speak, how many times the capacity of the plant can be used.[4]

46. We have a diversity not only between the various groups or classes of load which in their aggregate build up the central station's load, but also between the consumers of the same class amongst one another. If the consumers of every class would actually have the same load curve, as presupposed so far (Section 42), there would exist no diversity amongst them; in other words, the diversity-factor amongst them would be unity. As a matter of fact, however, there are differences in the load curves and consequently there is a diversity between the consumers of the same class; therefore, the diversity-factor between these consumers will be greater than unity.

An example will make this clear. Measurements have shown[5] in a certain city block of apartments containing 189 residential consumers that the individual maximum demands in these installations, if added up on paper, gave the sum of 68.5 kw. But the actual maximum output of the transformer supplying these 189 installations (and no other load besides them) was only 20 kw. The reason for the difference between these two figures is, of course, that the maxima in the various installations did not occur at the same time. Customer *A* might be entertaining one night in his residence with all his lights ablaze while *B* might that same night happen to use very little light; perhaps he is attending *A*'s party and all the lights in his residence are shut off. *C*'s demand may be a maximum one hour later than *D*'s demand, etc. The diversity-factor in this example would be $68.5/20 = 3.4$. If the demand cost of every kilowatt of transformer's maximum demand would be, for instance, $3.40 per month, there would be a cost of only $1 chargeable to every kilowatt of the consumer's maximum demand. (Of course, owing to the diversity between the various transformers of the system, the cost of the kilowatt of transformer's maximum demand will again be lower than the cost of the kilowatt of central station's peak load. Assuming for illustration that the diversity-factor between the various transformers of that station equals 2, then the demand cost per kilowatt of central station's peak load would be $2 \times \$3.40 = \$6.80$ per month, as against $1 per kilowatt of the maximum demand of the class of consumers in question.)

47. We have so far discussed only two examples of diversity-factor: among the residence consumers to the transformers and among the transformers to the central station. Evidently we can take any group of consumers (or loads) and speak of a diversity-factor among the constituents of that group to the total group. The constituents may again be subdivided into smaller groups. We may, for instance, choose the following successive divisions: Central station, substation, feeder, transformer, consumer, lamp, and then we might distinguish a diversity-factor among the elements of any one of these divisions to any other higher division, as follows:

Among substations to central station

{ Among feeders to substations;
among feeders to central station.

{ Among transformers to feeder;
among transformers to substation;
among transformers to central station.

{ Among consumers to transformer;
among consumers to feeder;
among consumers to substation;
among consumers to central station.

{ Among lamps to consumer;
among lamps to transformer;
among lamps to feeder;
among lamps to substation;
among lamps to central station.

In every one of these cases[6] we can again distinguish between the *individual* diversity-factor and the *average* diversity-factor. For instance, choosing the diversity-factor among the consumers of the same transformer, we can distinguish a diversity-factor of an individual transformer, or an average diversity-factor of all transformers on the same feeder, or of all transformers on the same substation, etc. (always

[1]Compare also Insert VI.

[2]Readers who are not familiar with the term "weighted average" will find an explanation in Insert VII.

[3]A more complete and general definition of the term "diversity-factor" will be given later (Section 49).

[4]In our above example we have for instance a plant of 4000 kw., whose capacity is distributed in such a manner that
at *A*'s peak-load time: 3000 kw. are used by *A*
+ 1000 kw. by *B* = 4000 kw.;
at *B*'s peak-load time: 1000 kw. are used by *A*
+ 3000 kw. by *B* = 4000 kw.

Assuming from the first one of these two conditions a subdivision of the plant's capacity in such a manner that 3000 kw. are set aside for *A*, and 1000 for *B*, we must conclude that 2000 kw. of *A*'s 3000 can be used over again for *B* at the time of *B*'s peak load and, as these 2000 kw. are one-half of the total plant capacity, this capacity can be used 1½ times. This way of looking at the meaning of the diversity-factor becomes still clearer if we assume more than two (for instance three) customers with the described load curves and the individual peaks occurring one after the other.

[5]Insull, "Central-Station Generation." Transactions A. I. E. E., 1912, page 246.

[6]Except in case of the diversity-factors taken directly to the central station.

meaning the diversity-factor among the consumers to the transformer).

48. Given a certain classification into divisions, for instance as chosen above in Section 47, we can distinguish a diversity-factor among the members of one group either to the next higher group (for instance, consumers to transformers) or to any other group above that (for instance, consumers to feeders or to substations). These latter diversity-factors may be designated as being "combined" from the "elementary" diversity-factors. The combined diversity-factor is the product of the weighted averages[7] of the constituent elementary diversity-factors.

If we take, for instance, the diversity-factor among consumers to a certain feeder as the combined diversity-factor, and choosing the diversity-factor among consumers to transformers, and among transformers to feeder, as the elementary constituents, then we have the following relations:

(a) Individual diversity-factor among the consumers connected to one certain transformer =

$$\frac{\text{sum of maximum demands of all consumers connected to transformer}}{\text{maximum demand of the respective transformer}}$$

(b) Weighted average over the whole feeder of the diversity-factors among the consumers to the transformers $= \dfrac{\text{sum of the numerators in (a)}}{\text{sum of the denominators in (a)}} =$

$$\frac{\text{sum of maximum demands of all consumers connected to feeder}}{\text{sum of maximum demands of all transformers connected to feeder.}}$$

(c) Diversity-factor among the transformers connected to one feeder=

$$\frac{\text{sum of maximum demands of all transformers connected to feeder}}{\text{maximum demand of the feeder}}$$

(d) Diversity-factor among the consumers connected to a certain feeder =

$$\frac{\text{sum of maximum demands of all consumers connected to feeder}}{\text{maximum demand of that feeder}}$$

By multiplying the fraction under (b) with that under (c), the denominator of (b) cancels against the numerator of (c) and we get the fraction under (d); this means:

The weighted average over the whole feeder of the diversity-factors among the consumers to the transformers $\times$ diversity-factor among the transformers connected to one feeder = diversity-factor among the consumers connected to one certain feeder (combined diversity-factor). This is in accordance with the aforesaid contention.

49. Now we can proceed to the general definition of the term "diversity-factor" as standardized by the American Institute of Electrical Engineers. This definition will now be understood more readily than if we had started the explanation of diversity with that definition. "Diversity-factor is the ratio of the sum of the maximum power demands of the subdivisions of any system or parts of a system to the maximum demand of the whole system or of the part of the system under consideration, measured at the point of supply."[8]

In shorter, though less precise, words we can say that the diversity-factor is the ratio between the sum of the maximum demands and the sum of the peak responsibilities or the average ratio between maximum demand and peak responsibility. It determines, therefore, the ratio by which the demand cost must be reduced from peak responsibility to maximum demand and this is the reason for the importance of the diversity-factor.

Statements about the numerical values of diversity-factors will be found in "Diversity-Factor," by H. B. Gear (Transactions A. I. E. E., 1910, page 375) and in a lecture by Professor Ryan (ELECTRICAL REVIEW, April 3, 1915, page 638).

We can also speak of the diversity-factor between groups of consumers which are not yet connected to the same system of supply. We may, for instance, have a number of neighboring towns, each served from its own central station. If we now scrap these generating systems and connect all those towns to one common station, this latter source of power will not have to be quite as large as the previous independent ones taken together, because the peak loads in the different towns will occur at more or less different times.

6. Variations of the Demand Cost per Kilowatt Maximum Demand Between Consumers.

50. It can be seen from the above that the demand cost, if reduced to the maximum demand of the consumer, varies in a large degree, owing to the diversity of the load curves.

There are other variations in the demand cost per kilowatt between the customers, due to other reasons, for instance the following:

51. The installations of small customers, that is, in general of the residential consumers, are generally scattered more widely apart than the large consumers' installations which are crowded together in the factory and business districts. The small installations require, therefore, a greater length of distribution lines, not only per installation but even more so per kilowatt installed. The transformers are greater in number and smaller in size for a given total capacity. The residences are generally located on the outskirts of the cities, away from the center of gravity of the system of power supply and consequently the transmission lines will have to be both longer and of larger section, etc. All this means greater investment and consequently greater cost of service due to increased interest and other capital charges.

52. Another element which affects the demand cost is the following: Electric light requires a high degree of constancy of voltage since 1% of voltage fluctuation causes more than 3½% fluctuation of the light, so that small fluctuations of the voltage may prove very annoying to the eye. We may easily notice this in some street cars, especially in interurban service, where the voltage regulation is adapted to the modest needs of the motor service only and not with a view to the exacting needs of lighting. Motor service, as just stated, is not as sensitive to fluctuations of the voltage. If it were not for the lighting service our distribution lines in the cities would contain much less copper and they would consequently be much cheaper. We are justified in saying that the capital charges for the extra copper necessary to reduce the necessary fluctuations from the power-service requirements to the narrower limits required by the lighting service should be charged as cost to the lighting consumers only and not to the power consumers.

This and other minor variations in the demand cost between consumers are generally disregarded when it comes to the computation of the cost and of the rates,

[7] Reference is here made again to Insert VII for those readers who are not familiar with the term "weighted average" (see footnote to Section 45).

[8] Transactions A. I. E. E., 1914, page 1797.

but it is well once to get a clear conception that they do exist.

53. In passing, we can return to the kilowatt-hour cost and mention that we have under this heading also variations in the energy cost between customers. (To explain these it has been necessary to first explain what the load curve is and the load-factor and the diversity-factor. Therefore, these variations in the energy cost could not be discussed in their proper place in Section 12 when we were dealing with the energy cost and the other classes of variations of this cost.)

If the load-factor of the customers and their diversity-factor is low, the transformers will run at low load during a large part of the time. Now the efficiency of a transformer decreases if the load on the transformer decreases below full load. Moreover, instantaneous copper losses in the transmission and distribution lines are proportional to the square of the power consumed (at given power-factor[9]); this means that the aggregate losses of energy for a given amount of energy transmitted during a given time are larger if the power is great during a part of the time and small during the rest, than if the energy is transmitted at a uniform rate. In addition to this the power-factor decreases at low transformer loads which increases the average current and therefore further increases the copper losses.

For all these reasons the energy cost will be higher with a poor load-factor and a poor diversity-factor than if these factors are good. But this increase in the energy cost is usually disregarded; taking it into account would make matters too complicated.

We will also see that there are variations in the third part of the cost, the consumer cost or customer cost, which part we are to discuss in the next installment.

Insert VII—Appendix to Footnote of Section 45.

Mean and Weighted Average.

Where we have to deal with averages of fractions or ratios, we have to distinguish between the "mean" average and the "weighted" average. The *mean* average is formed in the same way as the average of all other values, that is, by adding the values and dividing the sum by the number of values which are to be averaged. For instance, the mean average of $\frac{1}{2}$ and $\frac{1}{4}$ is $\frac{1/2 + 1/4}{2} = \frac{3}{8} = 0.375$. The *weighted* average is the sum of the numerators divided by the sum of the denominators. The weighted average of $\frac{1}{2}$ and $\frac{1}{4}$ is therefore $\frac{2}{6} = 0.333..$, but the weighted average of $\frac{50}{100}$ and $\frac{1}{4}$ is $\frac{51}{104} = 0.4093$; of $\frac{1}{2}$ and $\frac{25}{100}$ the weighted average would be $= 0.2549$.

The weighted average applies to such cases where the fractions are ratios and the numerators as well as the denominators are the results of physical measurements or countings or other observations. It is clear that before taking the weighted average, the fractions must *not* be reduced by the elimination of common factors. The larger are the values of both numerator and denominator of a certain individual ratio resulting from a certain observation the greater is the relative importance or weight of the respective ratio if we are concerned with the "weighted average," hence that name. With the mean average every fraction or ratio has the same "weight" as every other one.

An example will make this clear. Supposing, for instance, we would be interested in the average density of population in two neighboring towns—a city and its suburb—the city *A* having a million inhabitants on an area of 50 square miles and the suburb *B* having 10,000 inhabitants on 2 square miles. *A* has therefore a density of 20,000 inhabitants per square mile and *B* 5000. It would be obviously incorrect to say that the average density of population in the two cities is the average of these latter two values, *i. e.,* 12,500 inhabitants per square mile (mean average). The lower density of *B* will have much less weight in influencing the average density because *B* is so small in comparison with *A*. The correct value for the average density is the aggregate population of the two cities divided by their aggregate area, that is the weighted average, $\frac{\text{sum of numerators}}{\text{sum of denominators}}$ or $\frac{1,000,000 + 20,000}{50 + 2}$ $= 19,615$ inhabitants per square mile.

(*To be continued.*)

[9]The non-technical reader will find an explanation of the term power-factor in Insert X.

IMPORTANT FACTORS GOVERNING SOUTH AMERICAN ELECTRICAL TRADE.

Valuable Information Contained in Pamphlet Being Distributed by Guaranty Trust Co.

Considerable valuable information regarding the opportunities for the sale of electrical material in South America is contained in a pamphlet being distributed by the Guaranty Trust Co. of New York City. According to this information two factors play a dominant part in dictating the purchase of the materials used by railway, street railway, light and power, and other public service companies in this country.

The first of these is that South America does not itself produce any of this material and, consequently, it must be imported. The second factor is that nearly all such companies are financed by foreign capital and the almost irresistible tendency is for them to purchase their material in the country from which the capital comes. This second factor is declared to be the key to the entire situation and some pains are taken in the article to explain the policy and viewpoint of European peoples, as compared with our own, in respect of the persistence of nationality in corporations established abroad.

Each country of South America is taken up alphabetically and its general economic features considered briefly. There follows then a list, by groups, of the important companies in that country which use electrical supplies. The information in regard to these companies includes ownership, capitalization, extent of business, conditions of operation, etc. It is calculated to furnish the essential facts for those interested in extending their markets in those countries or in establishing new ones.

PLANS PREPARED FOR TUNNEL UNDER MT. BLANC.

Electric Railway of 50 Miles Proposed, of Which Tunnel Will Include 10 Miles.

A special cable dispatch, dated Aug. 3, from Rome, Italy, to the *Chicago Tribune,* states that negotiations are being concluded between a representative of a French syndicate and the Italian Government for the construction of a tunnel through Mount Blanc, which will be one of the greatest projects to pass through the Alps. Studies for the project have been going on for about fifteen years. It is now proposed to build an electric railway from Chamonix in Savoy to Amsta in the province of Turin, a length of 50 miles, whereof 10 will be under Mount Blanc. The new railway will join two of the most celebrated valleys with magnificent scenery and perhaps the most renowned among all picturesque cities of the Alps.

Factors Affecting Heat Absorption of Boilers

How Heat is Transmitted—Effects of Scale and Soot and the Importance of Removing or Preventing Them—Tests that Prove Advantages of Mechanical Soot Blowers

By ROBERT JUNE
Mechanical Engineer.

HEAT is transmitted to the water within a boiler by three processes,—radiation, convection and conduction. Radiation originates in the fuel bed, and hot furnace walls, convection in the hot traveling gases, and conduction is a function of the metal of the boiler. The generally accepted theory of the part each of these processes plays is illustrated in Fig. 1. In this illustration it is also shown that the heat has to penetrate five layers of interfering substances, namely, a film of dry, stagnant gas, a layer of soot, the metal of the tube, a layer of scale and a film of dry steam.

With the exact or relative values of radiation and convection, we are not here concerned, except to observe that on account of the limitations of refractory materials, there is no great hope of increasing furnace temperatures in this way in the immediate future, and that if we are to increase boiler capacity, it will have to be through agencies other than by convection. Inasmuch as we can greatly increase the amount of the boiler surface exposed to radiation, this is the principal line along which we are to look for improvement in boiler and furnace design.

Hardly less important, however, is the necessity for devising means of dispersing the dry gas and steam films on either side of the tube. These films are extremely poor conductors of heat. It has been found, as a result of experiments by Professor Nicholson, and the United States Geological Survey, that by establishing a powerful scrubbing action between the gases and the boiler plate, the non-conducting film of gas can be torn off as rapidly as it is formed, thus bringing new portions of the hot gases into contact with the tube, and thereby greatly increasing the rate of transmission. Similarly, the faster the circulation of the water, the greater will be the scrubbing action, tending to remove the bubbles of steam from the wet surface, and the more rapid will be the transfer of heat from the tube to the water. By filling up the tube of a Cornish boiler with an internal water vessel, leaving an annular space of only one inch around the latter, Professor Nicholson found that it was possible to drive the boiler to 800% of normal rating, with a flow of gases of 330 ft. per sec. This flow, which is 8 to 10 times the average, was maintained by a fan, utilizing about 4½% of the total power generated.

These factors in heat transmission have been mentioned because they presage certain important improvements sure to come in boiler and furnace design, and it is the duty of prospective boiler purchasers to be informed of them, to discuss them with the boiler manufacturers, and to lend every encouragement to the latter in their work of devising cheaper means of steam production.

Importance of Preventing or Removing Scale Formation.

Coming now to practical questions of every-day operation, it is found that the formation of scale is a factor of design only in a limited degree, being chiefly dependent upon the rate of driving and the nature of the scale forming ingredients in the feed water. That the formation of scale should be absolutely prevented by purifying the feed water, or that it should be removed as rapidly as it forms, by scale cutters, or "tube cleaners," as they are called, is one of the most elemental facts in efficient boiler room operation.

The loss in conductivity, due to the presence of scale, has never been reduced to a rule or formula, depending upon the thickness, or the degree of hardness and thickness or the chemical composition of the scale. The percentage of loss, therefore, can only be determined in each case by actual tests.

The following table shows the results of a number of tests of loss due to scale, made at the University of Illinois. It will be seen that the results are so varied as to prevent any detailed conclusions but they do point unmistakably to the very great loss caused by scale, running from 2% to 19%, and they also point to the previously stated very great necessity of absolutely preventing soot formation, or, failing this, its removal as soon as formed.

Influence of Scale on Heat Transmission.

Test No.	Thickness of scale.	Character of scale.	Decrease in conductivity due to scale, per cent.
1	.0	Hard, dense	9.1
2	.02	Hard	2.02
3	.033	Soft	4.3
4	.033	Very hard	3.5
5	.038	Medium	4.03
6	.04	Soft, porous	6.82
7	.04	Hard, dense	3.07
8	.042	Very soft	9.54
9	.047	Hard	2.75
10	.065	Medium	2.39
11	.07	Soft	2.38
12	.07	Hard	4.43
13	.085	Soft, porous	19.0
14	.089	Very soft	4.95
15	.11	Hard, porous	16.73
16	.13	Hard, dense	6.75

Dangers of Soot Accumulation.

Soot, as has been stated before in previous articles, is the most troublesome source of preventable waste in the boiler plant. With the exception of scale, all other losses are of such a character that when once located they may be practically eliminated for all time by the single application of corrective measures. This holds true of losses caused by air leakage in the setting, losses due to radiation, excess of air through the furnace, etc. But there is no means of preventing the formation of soot. Its deposit on the fire surfaces of the boiler is an ever continuous process.

It is a matter of frequent surprise, not only to the layman, but to many men experienced in boiler room practice to learn that soot is the second best heat insulator known. Its lack of the property of conduction is so great that it has been proven to be more than five times as effective as fine asbestos in prevent-

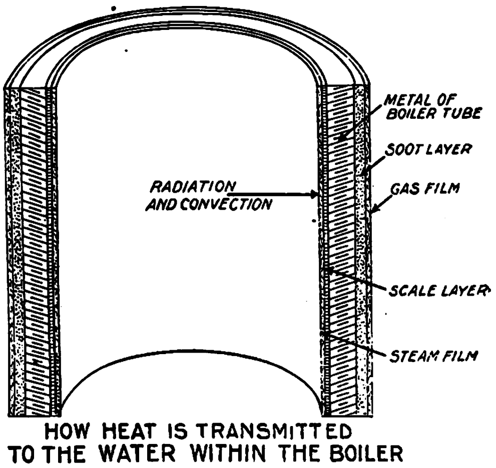


Fig. 1—How Heat Is Transmitted to the Water Within a Boiler.

ing heat transference; that is, more heat would reach a boiler through a 1-in. wrapping of asbestos than through a 1/5-in. coating of soot. To emphasize the importance of soot removal two tables, which appeared in a previous article by the author are reproduced herewith, together with a description of soot as found in the boiler plant.

The first of these tables, from Kent's Mechanical Engineers' Pocketbook, is as follows:

Comparative Resistance to Heat.

Thickness of each substance............................ 1 in.
Temperatures applied to each............................ 310° F.
Temperature increase of water in each case........... 10° F.

	Substances.	No. of pounds of water heated.
1.	Loose wool	8.1
2.	Loose lampblack (soot)	9.8
3.	Hair felt	10.3
4.	Carded cotton wool	10.4
5.	Fine asbestos	49.0

A perfectly clean boiler tube, ⅛-in. thick will transmit 40 times as much heat as will a tube covered with a one-inch thickness of soot.

The loss in the heat conductivity of boiler plants due to soot deposits may be noted in the following table:

Thickness of soot.	Per cent of loss.
1/32 in.	9.5
1/16 in.	26.2
1/8 in.	45.3
3/16 in.	69.0

Fortunately, soot does not collect on all surfaces of a boiler in the same proportion. Some portions may be fairly clean, while others are thickly coated, but this does not lessen the fact that there is a considerable loss of fuel and heat wherever even a portion of the tubes are coated.

Composition of Soot.

The principal constituent of "pure soot," or lamp black, is carbon. Mixed and associated with this carbon, are various tar products and acids. In color, soot varies from black, to gray, grayish white, grayish green, grayish blue, brown and reddish brown.

Soot as found in steam boilers varies considerably in appearance and composition, depending upon the grade of coal burned, condition of combustion, and the part of the furnace from which the sample is taken. Nearest the fire, the deposits formed consist largely of ash. Analysis of samples of soot taken from the first pass of a boiler show, in addition to "pure soot," the presence of silica, alumina, iron oxide, various alkalis and sulphur dioxide.

In all but the coolest portion of the setting, soot is usually gritty in texture. The grains may be as large as medium sand, or as fine as cigar ash. These particles are in a plastic state when they leave the furnace, and striking the lower portion of the boiler, they adhere to the tubes. If this deposit is not removed frequently, it quickly increases in amount and changes in character. The carbon burns out in part and the mass cements together. The repeated reduction in heating surfaces, increases the temperature of the flue gases, so that the process of cementation is continuous and constantly increasing in intensity. An extremely hard clinker-like formation results and in a short time the space between the tubes in portions of the boiler will become entirely blocked, thus materially reducing its capacity. In this condition, mining operations alone will remove the deposits.

Another bad feature of these deposits is that if they are allowed to remain, the corrosive action of the various constituents of the soot is very apt to cause leaky tubes. Under the influence of heat, a ferrous carbonate is formed. The excess of air that is always present, brings free oxygen into contact with the ferrous carbonate, and the reaction produces ferric acid. Carbonic acid, particularly in the presence of free oxygen, acts very rapidly on the metal of the

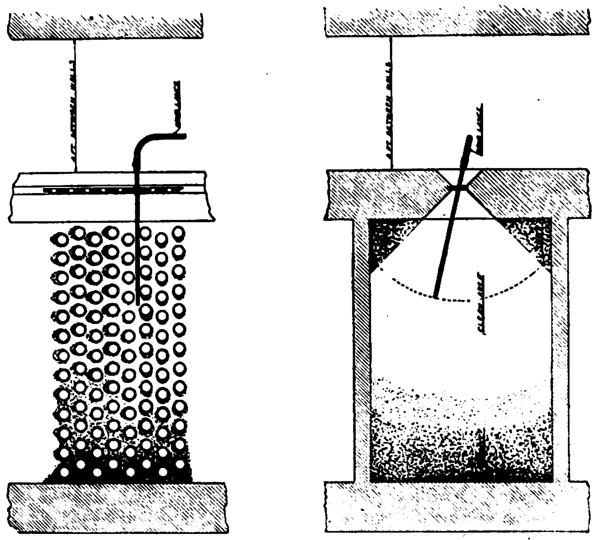

Fig. 2.—Why Hand Hose Is Ineffective.

boiler. Another source of corrosion is the sulphur dioxide in the soot, which changes first to sulphurous acid, and then to sulphuric.

Only the boiler-insurance companies know exactly how many boilers are condemned annually as unfit for operation on account of such action, years before their natural period of service would terminate. That the number is very high however, is generally admitted, for such cases are being constantly brought to light.

Hand Cleaning Not Effective.

It is a mistake to think that soot can be suitably removed by the hand-hose method using steam, through a rubber hose and nozzle. The use of this system arose in the sheer necessity for removing some of the deposits from the tubes. It is admittedly an inefficient and expensive process, as well as being an extremely disagreeable, and, to a certain extent, dangerous one.

Two men are required in this process, one close up to the boiler setting, frequently on a ladder, and the other, at the steam valve. The time employed is usually from 20 to 30 minutes. The nozzle is inserted, the spray of steam goes into the boiler, but whether it reaches all of the soot-covered parts of that section can not be determined. For example, there is a section near the cleaning door which cannot be reached at all. In addition a large supply of steam is used and an immense amount of cold air is let into the furnace. When the hose is moved to the next location, some of the soot will be blown back.

Effects of Soot on Boiler Efficiency.

When the velocity of the gases over boiler surfaces is doubled and there is a corresponding increase in combustion rate and load, if the surface is maintained clean of soot coatings and ash deposits, two times as much heat is absorbed by each square foot of surface. The temperature of the waste gases is but little or no higher than of the gases formerly discharged from the boilers when they were operated at low loads, with a sluggish flow of gases, and soot-coated tube surfaces.

In both marine and locomotive boilers 10 lb. of evaporation per square foot of heating surface is common practice, higher than this being often obtained. There is, therefore, no real reason why stationary boilers may not be driven at these ratings. The principal requirements are scrupulously clean tubes, inside and outside, the latter requiring efficient mechanical soot cleaners.

Boilers must be cleaned more frequently when forced than when operated at rating, and the maintenance of both boiler and setting must be considered, and while this may appear to be against the use of

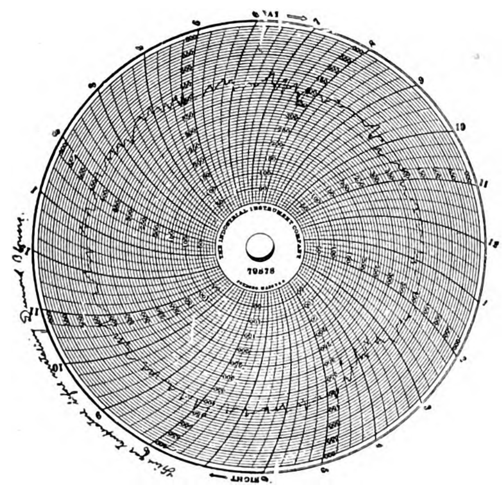

Fig. 3.—Flue Temperatures Before Installing Mechanical Soot Blowers.

high ratings, it is not as serious as it may seem. Boiler repairs and tube replacements under forced conditions are no more necessary than at lower ratings, provided the boilers are kept clean. If the boilers are to conduct heat as rapidly as possible to the water within the tubes, the steam is to be kept up when the soot piles up, more coal will have to be piled in.

The Five Essentials in Preventing Soot Waste.

The five essentials in preventing soot waste are:

1.—Frequency in cleaning. In order to minimize the cumulative effects of increasing deposits tubes should be cleaned three to six times a day.

2.—Thoroughness in cleaning. In order to maintain high furnace and boiler efficiency, and prevent

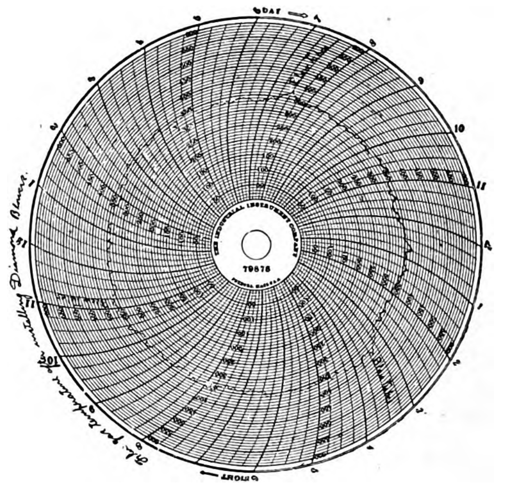

Fig. 4.—Flue Temperatures After Installing Mechanical Soot Blowers.

the destructive corrosive effects of soot accumulation.

3.—Availability of system. The soot-cleaner system should be instantly available, automatic in action, capable of rapid operation.

4.—Durability of system. The blower units should be so designed and constructed that they will withstand the stress of hard service, when placed in the hottest portions of the boiler, without the necessity for frequent repair or replacement.

5.—Economy of operation. The soot-removing system should require less steam and labor than hand-blowing; it should be installed so as to prevent the entrance of cold air into the furnace during operation; and, it should pay for itself from an investment standpoint.

The following figures from one of the largest electric plants in the country for a new and perfectly clean 1000-hp. horizontal water-tube boiler operated at 150% rating indicate the bad results of permitting soot accumulation:

Uptake temperatures for 1st day were an average of 550°.

Uptake temperatures for 2nd day were an average of 575°.

Uptake temperatures for 3rd day were an average of 600°.

Uptake temperatures for 4th day were an average of 625°.

Uptake temperatures for 5th day were an average of 650°.

These boilers were not cleaned and the figures given are good indication of the rapidity with which soot insulates the tube surface and cuts down economy as the time increases during which a boiler has been in service. An increase of 100° in flue gas temperatures in four days represents an increase in coal consumption of approximately 5%.

Tests Prove Soot Blower Savings.

The following data regarding soot-blower tests indicate the results to be expected by the use of soot blowers. The first of these tests was made at the plant of the General Electric Co., Schenectady, N. Y., and indicates a 6% saving in fuel. The data was obtained from tests by A. L. Rohrer, electrical superintendent of the General Electric Co., in which he states:

"Replying to your inquiry concerning the trial installation of Diamond Soot Blowers, made in our power station here, I beg to say that perhaps I cannot do better than to give you some data obtained by several tests, each of which cover a period of two weeks. During tests both boilers had tubes blown twice in 24 hours, and in each case the same boiler was used for the hand-blown test. The data given is the average obtained during runs:

Before Using Soot Blower.				After Using.			
	Temperature				Temperature		
Time. A. M.	Stack.	Sup. steam.	Load meter.	Time, P. M.	Stack.	Sup. steam.	Load meter.
10:15	550	500	4.2	2:30	485	495	4.2
10:30	550	502	4.0	2:45	485	506	4.0
10:45	555	498	4.0	3:00	482	504	4.3
11:00	557	498	4.1	3:15	483	505	4.2

	Test results Before.	After.
Load meter	4.075	4.175
Per cent rating	101.88%	104.38%
Steam pressure gage	199.5 lbs.	200.75 lbs.
Superheated steam temperature	499.5 F.	502.5 F.
Stack temperature	553 F.	483.75 F.

From Oct. 8 to Nov. 4, 1916, the General Electric Co. ran a comparative test of mechanical soot blowers

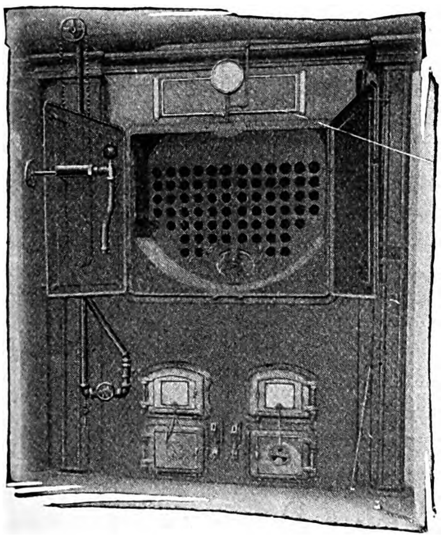

Fig. 5.—Mechanical Soot Blower in Return Tubular Boiler.

and the hand hose method on two 500-hp. boilers, set in the same battery, and identical in design, stokers, general equipment, and operating conditions. The results were as follows:

Average production of two boilers, 26 days—10,500,000 lb. steam.

Boiler No. 5, hand hose, at $0.17 per thousand	$1,785
Boiler No. 7, Diamond equipment, at $0.16 per thousand	1,680
Saving, 26 days	105
Estimated saving, 300-day year	1,260

	Hand hose method.		Soot blowers.	
Time of tests.	Flue temp.	Per cent rating.	Flue temp.	Per cent rating.
Two weeks ending Oct. 7	586	128	553	140
Two weeks ending Oct. 20	635	133	563	141
Two weeks ending Nov. 4	630	126	560	154

The results of another soot-blower installation are contained in the data furnished by A. J. Fisher, chief engineer, on two 500-hp. boilers at the company's plant of the Miami Electric Light & Power Co.

Decrease in coal consumption since Jan. 1, when soot blowers were installed, 217.5 tons, or 6.5%. Increase in output for same period 294,682 kw-hr. or 25%. This represents a saving in coal alone for this period, Jan. 1 to Sept. 30, of $1196.25 over the same period of the preceding year.

From the tests made by J. A. Switzer, professor of Hydraulic Engineering, University of Tennessee, at the plant of Brookside Mills, Knoxville, Tenn., for the owners, the following data was obtained:

From the results of the test at boiler plant No. 1, made with a view of determining the saving effected by the installation of mechanical soot blowers, it appears that the saving brought about amounts to 7%. This represents a saving of one ton of coal during the 10 hours' period. Had the test covered a 24-hour period, so as to include the coal burned for heating the mill during the night, as well as for the hours of running, before and after the 10 hours' test period, the saving would amount to approximately 1¼ tons of coal. Accordingly it is perfectly safe to state that the soot blowers will completely pay for the cost of installation in somewhat less than six months' time. In view of the service which the soot blowers are rendering at this boiler plant, Professor Switzer strongly recommended that blowers be installed in boiler plant No. 2 of the company. In reference to the last, he stated that it was his belief that the soot blower would show a saving certainly not less than 10%.

From the tests made on two 822-hp. boilers using fuel oil at the plant of the Pacific Gas & Electric Co., San Francisco, it is shown that the soot blowing caused the temperature of the stack gases to fall from 553° F. to 483.75° F., making a difference of 69.25° F., or 13.05%. Also the temperature of the superheated steam was raised from 499.5° F. to 502.5° F., a raise of 3°, or 0.6%. The direct effect of the use of soot blowers, therefore, is a saving of 3.9%.

It will be observed that in every test the boiler equipped with mechanical soot blowers gave higher rating with lower flue gas temperatures and shows a higher efficiency in heat transference.

WINDMILLS USED ON DENMARK FARMS TO GENERATE ELECTRICITY.

During the coal famine caused by the war many attempts were made to improve the working of the windmills geared to dynamos to generate electricity. About 250 installations on farms and small estates have proved fairly satisfactory. Many experiments in this connection were carried out by the late Mr. P. la Cour, and a trial mill designed by him is still being used for observation purposes. During about one-third of the year there was either complete absence or excess of wind, and the force available was very variable. It was nevertheless found possible to save fuel for steam or gas-driven power producers. The cost per kilowatt from peat gas fired plants is approximately the same as from a windmill-driven installation. Attempts were made to design special three-phase dynamos capable of maintaining constant voltage independent of the speed of the mill, special attention being also paid to automatic adjustment of the sails in order to reduce the cost of attendance. A mechanical contrivance effects a turning movement of the sails so that during very high winds these occupy a position parallel to the direction of the wind, thus avoiding damage to the mill. Attention has also been paid to gearing and bearings to minimize losses in transmission from the sails to the dynamo.

Editorial Comment

Electric Drive on Hydraulic Dredges

HYDRAULIC dredges offer a large field for the application of electric drive and one that has only been barely touched up to the present time. On this account the description of the dredge operated by the City of Oakland, Cal., and the savings which it effects, as shown in the article by C. W. Geiger in this issue, should be of considerable interest to electrical men.

Undoubtedly this particular dredge in its operations is especially well adapted to the use of electric power but there are many others in various sections of the country which are operating under similar conditions and many more where a substantial saving could be made by the installation of motor drive.

Keeping After the Soot

SOOT is the arch enemy that interferes with the transfer of heat from the furnace gases to the contents of the boiler. By careful firing and combustion approaching the ideal, soot can be reduced, but not eliminated. Only those most closely concerned appreciate the amount of soot deposited upon heating surfaces of boilers and surfaces in close proximity during a day, a week or any other period of time, and in doing so acts as an almost perfect heat insulator.

But if the formation of soot cannot be prevented, it does not necessarily have to form a heat-insulating covering upon the heating surfaces. Prevention is better than cure, and soot should be removed with sufficient frequency from the boiler heating surfaces to prevent it from seriously interfering with heat transfer. The mechanical soot blower possesses the very real advantages that soot can be blown whenever conditions are thought to warrant, and without stopping steam making or taking a boiler or fire out of active service.

The mechanical soot blower would seem a necessity in these days when striving for economical boiler rooms. It is undoubtedly a necessity in the larger units with their high capacities and high rates of combustion. The mechanical soot blower is no longer an adjunct but a necessity in the large boiler room of today.

Carnegie and Haeckel

TWO famous men, both men of remarkable talents and drastic limitations, both in a peculiar sense the products and exponents of the later eighteenth century, both of a venerable age, have passed away within a few hours of each other. Carnegie, the Scottish-American ironmaster, and Haeckel, the German scientist, have passed out into the Great Unknown.

Carnegie, better than almost any other man, represented the industrial development which came with and followed the age of invention that began about 1870. Every new process in mining and smelting of iron or in the making and forging of steel paid Carnegie a profit. He did much, perhaps more than any other one man, to introduce efficiency into the steel industry, hence it was he who may be said to have been the sponsor of electricity in the steel industry. Incidentally, Carnegie was one of the first three men able to read the Morse code by sound.

As Carnegie typifies the later nineteenth century in industry, so Haeckel typifies it in science. Haeckel was a disciple of Darwin, only he was possessed of a dogmatism never seen in the gentle English student. To him, evolution was more of a deity than a truth, and he clung to the notion that there was no mystery but that would be explained in time with a fuller understanding of evolution. Haeckel was a militant missionary of science, unconsciously reflecting, perhaps, the influence of the militaristic society in which he lived and which he accepted with an almost childlike faith.

Both these men were of abounding talents, of kindly personality, both tireless workers. Both were keen investigators, daring in their divers ways and both were many-sided, brilliantly so. Both have served the world. To consider two such men together, their characteristics or their achievements, can only remind one of the infinite variety of the world.

Public Utility Dilemma

ALMOST every day comes to this office details of another municipally owned and operated light plant that has failed. Meanwhile the agitation for municipal ownership goes on, with its optimism, its falsehoods, prevarication, wrong theories and Utopian dreams.

High costs of fuel, of labor and supplies, loss of revenue and inability to do this and that are the reasons that so many of the municipal plants are going under. Meanwhile, privately owned and operated systems must keep going for the reason that they cannot quit. Their position is in many instances not an enviable one, for they must wait until relief comes in the form of higher rates of revenue or lower rates of expenditure, the former dependent upon public opinion, the latter upon world conditions.

The public and the politicians that allow the municipal plants to close down and cease functioning, are the same public and politicians that turn a deaf ear and refuse relief to the privately-owned plant that must keep on generating and distributing service. Is this fair play? And is it wisdom?

Psychology and Car Fares

WHILE the troubles of the traction companies were being aired before the Federal Electric Railway Commission in Washington, Secretary of War Baker, one-time mayor of Cleveland, expressed it as his opinion that the five-cent fare for street car rides in cities was a "psychological necessity," higher rates probably reducing the profitable short haul business. Mr. Baker admitted higher fares might be an emergency measure, "But if fares are raised," he said, "they ought to be raised by the people who are to pay for the increase. Otherwise it will be resented."

He who pays the piper calls the tune. Higher car fares should be granted, when granted, by those that will have to pay the higher fare. Higher fares ordered by commissions far-removed from the locality concerned will not meet with public sanction, but will tend, instead, to breed opposition and resentment. The company needing more revenue and seeking to obtain it by increasing its fares will do well to place the matter fairly and squarely before its patrons. This is the one and only way in which higher fares can be obtained without bringing with them ill-feeling.

Demand Cost and Diversity-Factor in Public Utility Service

FOR quite a few years it has been known that a high diversity-factor is an important means of reducing the cost of rendering central-station service. This means that serving many classes of customers with diversified demands spreads out or levels off the peak load and by thus reducing the necessary capacity of the central station decreases its fixed charges. The consequent reduction of the demand cost is thus closely dependent on the diversity-factor. Diversity of demands makes the reduction of the plant's generating capacity offset the cost of the distribution system and this, combined with the much higher efficiency and lower unit cost of large generating units accounts for the superior economy of the central station as compared with the isolated plant.

In the sixth of the present series of articles on "Central-Station Rates in Theory and Practice," by Mr. H. E. Eisenmenger, which appears in this issue, the author brings out very clearly the relation between diversity-factor and demand cost in central-station service and applies it in detail in several cases. The principles he brings out are applicable to all kinds of public utility service, although up to the present at least they have been applied to only a very limited extent outside of electricity supply service.

Failure to recognize the heavy additional cost of meeting the peak loads (rush-hour traffic) of street-car service is one of the reasons for the sad plight of so many traction companies at this time. The capital tied up in the great number of extra cars, heavy feeders and generating plant needed to handle the rush traffic of only a few hours each work day is idle the rest of the time. Consequently the fixed charges are greatly in excess of what they would be if the traffic curve were leveled of its peaks, which means more diversified service should be developed. On lines in industrial communities this may be difficult at first sight, yet spreading out of the peak load should not be difficult if effort is made to secure the co-operation of the industrial plant managers in spreading out the time of starting and quitting work. The supreme folly of this matter is the practice followed in quite a few industrial communities, up to quite recently of giving lower fares to workmen during the rush hours than at other hours of the day. We are not ready perhaps to accept higher fares during the rush hours than at other times, but this is the logical method of reducing the rush-hour traffic as well as apportioning the higher charges of this traffic among the passengers responsible therefor. At the very least the lower rush-hour fares should be abolished where they still are required and every effort made to spread out the traffic as much as possible.

Telephone service has its rush-hour traffic also, this requiring a much more expensive plant equipment than if the traffic were more evenly spread out. Telephone companies have not felt free to exact higher rates for peak-load service and it is doubtful whether they ever will. About the only effort made to develop use of otherwise practically idle equipment is the practice of offering lower long-distance rates during the night hours. Greater diversity of service is possible of development, however.

Water and gas supply companies have the same problem also, but seldom, if ever, attempt to reduce maximum demands by means of the rate schedule. Yet large reservoirs and gas holders are needed to meet the peak-load demands. There is no branch of public utility service that can not profit from consideration of the manner in which the central stations have met the problem by developing higher diversity-factors. Mr. Eisenmenger's articles therefore contain much of interest to other utilities and the managers of central stations are not the only ones that will find in them food for profitable thought.

Unification to Benefit Pacific Coast

INTERCONNECTION of generating systems received great impetus during the war on account of the saving of fuel and the availability of generating capacity obtainable thereby. When the emergency ceased the need for the remedy also abated, at least so far as the need was less prominently acute. However, interconnection was found so beneficial in many instances that it has come to be a permanent measure instead of a war measure. And interconnection of different systems by different companies has in many cases come to be the unification into one company, as under some conditions it should be in the best interests of the public, the utility and the territory served.

It is in California that interconnection of systems made great progress both before and during the war. Distances were great, settlements were widely scattered, and water powers were numerous with varied stream flow, different pondage capacity and availability for utilization. By interconnecting sources of energy, stream flow could be utilized to the full, diversity could be taken advantage of efficiently, water power could be made to replace steam wherever possible and power available where not needed could be transmitted to markets where there was a shortage.

A number of important interconnections were made in California during the war, thereby saving oil and utilizing water power, but the war came to an end before ambitious plans could come to their full fruition. However, the benefits indicated were such that the movement has continued. The latest movement in this direction is the purchase of the Northern California Power Co. by the Pacific Gas and Electric Co. For some years the interests of these two large companies have been closely interwoven and during the war at the direction of the Power Administrator of California the two systems interconnected, the Northern California Power Co. thus becoming the central link in a chain of high-tension lines that reach from the mountains of Oregon to the Bay of San Francisco. It has already been prophesied that it will not be many years before a chain of interconnected transmission systems link up Oregon with the Mexican border. The acquisition of the Northern California Power Co. by the Pacific Gas and Electric Co., and the attention now being given to the adoption of 220 kilovolts as a commercial voltage lead one to expect that things will move apace during the next few years.

The unification of two large utilities, serving vast territories and harnessing many small water powers is pregnant with possibilities for California. The Northern California Power Co.'s property with its 525 miles of high-tension line, 1611 miles of low-tension lines, its six hydroelectric generating stations aggregating 50,000 horsepower on Battle and Crow Creeks respectively and its power site on the Pitt River representing potentially 90,000 horsepower will now enable the Pacific Gas and Electric Co. to expand to meet the ever-growing demands for power, develop latent power resources for utilization in the near future, and use existing water flow to best advantage. The unification of these two Californian utilities is of importance to the electrical industry as a whole and it is of greatest moment to the Pacific coast.

The Pacific Coast needs more industries, and industry consumes electric power. Interconnection spells fuel economy, conservation of water power and industrial development.

Industrial Unrest

INDUSTRIAL unrest is universal. From coast to coast, in almost every industry in the country has come discontent or smoldering discontent is on the verge of springing into flame.

Police, firemen, railroadmen, and others in positions of public trust have gone on strike or threatened to strike for shorter hours, higher rates of remuneration, or better working conditions, or from sympathy. While we clamor for a lower cost of living, labor is insisting upon conditions that not only precludes lowering the cost of living but must necessarily increase it. Unless something is done and done soon, this country will face an extremely acute and hazardous situation. We are heading at high speed toward a calamity.

It is natural that the World War that turned the world upside down, should be followed by upheavals and readjustments. It was inevitable. But the tendency of these upheavals, these movements, is for labor to prosecute its own interests without taking into consideration the interests of others. Labor today is passing through a much exalted opinion of itself and its value to the world, and it is this latter that, after all, is the criterion of worth. If labor would serve its own best interests and those of the country as a whole—and the need for patriotism is with us still—labor would do well to tackle the urgent and complex problem of lowering the cost of living instead of making things worse by insisting upon higher wages, wages in many instances out of all proportion to intrinsic worth. To do the former would strike at the root of the problem; doing the latter is no solution, not even a palliative to the most pressing problem this country faces today.

No country can continue to progress healthily unless its progress is founded upon a firm basis. Inflated prices and labor costs and an excessively exalted opinion of labor for itself and its value to the community do not work for this condition. The value of labor itself depends not upon itself alone but upon those using and utilizing its labor.

We need more give and take, closer harmony, co-operation and mutual appreciation of moral obligations between capital and labor, the curtailment of the profiteer to a point where he ceases to be a menace to our national life, that all can start again, energetically, the work of peace, and bring about increased production, better distribution and fair play all round. For it is these three, increased production, better distribution and fair play, and these alone, that will bring about lower cost of living and industrial rest.

Current Events

Program for Illuminating Engineers' Meeting—New Code Committees—Chicago's Electrical Show—Convention Plans

BROAD PROGRAM FOR ILLUMINATING ENGINEERING SOCIETY CONVENTION.

Topics of Interest to All Branches of Lighting Industry to Be Included in Program of Chicago Convention.

A tentative list of subjects to be included in the program of the 1919 convention of the Illuminating Engineering Society at Chicago, Oct. 21 to 24, inclusive, has been announced by the Papers Committee, of which George H. Stickney, Harrison, N. J., is chairman. A "high spot" at the beginning of the program will be the report of the Committee on Progress which will review not only the normal progress of the year, but the lighting developments during the war, including, if possible, some of the new things which heretofore have not been openly discussed. Searchlights, their development and application during the war, will be another interesting feature.

A paper on "Viaduct Lighting" will describe an installation made without poles or posts and involving an unusual and interesting method of distributing light over the roadway with provisions for reducing glare; this paper is to be accompanied by illustrations and curves. The gas-lighting industry will be represented with a paper on gas street lighting, its present status and recent developments. Recent developments in equipment and applications of electric street lighting will also be discussed.

A paper which will not be printed in advance is one on prospective lighting applications. This will be a "ginger" talk, pointing out the extensive and as yet undeveloped field for the wider application of artificial lighting.

For the industrial man there will be several papers. One entitled "Industrial Lighting" will give data and descriptions of good lighting installations recently put in under the advice of experts of important central stations; figures on burning hours, etc., will be included. What the manufacturer says he is doing in regard to good industrial lighting will be brought out in a paper entitled "Industrial Lighting Survey."

The recent movement for lighting codes for various states has been recognized by placing on the program a symposium on the application of industrial lighting codes. State experts will give their experience in applying and enforcing these codes. Results of insurance companies' inspections will also be brought out; the importance of insuring industrial safety by means of regulations of lighting will center much interest on this topic.

A message from the merchandiser to the illuminating engineer will be included in a paper entitled "Illuminating Engineering and Merchandising." This paper will tell how to encourage better lighting practice among dealers of lighting equipment. A paper on "Hospital Lighting" will bring out what illuminating engineers believe is good practice as exemplified by modern installations.

There is also enough of the technical in the program to make it well balanced. "Tests of Lighting Units" will bring out facts about photometric and illumination tests of typical units for interior lighting. "Diffusion of Light" will discuss a study of glare and diffusion in their relation to practical lighting installations. "Distribution of Light in Rooms" is an analysis of natural and artificial lighting with regard to wall finish, window openings, shading, etc. A paper on the "Reflecting Power of Paint" will contain data from careful tests of different colored paints. "Photometry" is the title of a paper which will bring out some ingenious methods of making difficult measurements.

From the foregoing condensed summary of the principal topics, it is evident that the program will not neglect any of the chief lines of lighting activity, commercial and practical as well as academic and theoretical. For this reason it is hoped that the convention will attract many men from every branch of illumination science and art.

MUNICIPAL ELECTRICIANS TO HOLD INTERESTING CONVENTION.

Four-Day Meeting Being Planned in Chicago Sept. 23-26—Exhibits and Entertainment Not to Be Neglected.

Arrangements are rapidly being perfected for the 24th annual convention of the International Association of Municipal Electricians which will be held at the Auditorium Hotel, Chicago, Sept. 23-26, inclusive. The technical program cannot yet be announced, but it can be stated that it will include reports, papers and addresses on timely topics of unusual interest. An exhibit by manufacturers of electrical apparatus and supplies used by municipal electrical departments will be a feature supplementing the program. An entertainment program is being worked out that will provide relaxation between the sessions and pleasant diversion for the ladies during the technical sessions. Clarence R. George, Houston, Texas, is secretary of the association, and William S. Boyd, 175 West Jackson boulevard, Chicago, is secretary of the local committee on arrangements.

COMMITTEES APPOINTED TO REVISE NATIONAL ELECTRICAL CODE.

Persons Interested in Code Revisions Invited to Communicate with Subcommittee Chairmen.

The following special committees have been appointed by the chairman of the Electrical Committee of the National Fire Protection Association to consider various questions in anticipation of the 1920 Code. All persons interested in any of these questions are invited to communicate with the chairman of the technical subcommittees as given below.

These subcommittees grouped under the standing committees through which they will report are as follows:

1.—Standing Committee on Cars and Railways: M. Schreiber, chairman, American Electric Railway Association, Newark, N. J.; R. C. Bird, Ralph Sweetland. In the revision of rules on carhouse wiring and car wiring for more than 600 volts the American Electric Railway Engineering Association has appointed two committees to co-operate with the standing committee.

2.—Standing Committee on Devices and Materials: A. R. Small, chairman, 207 East Ohio street, Chicago; H. O. Lacount, H. R. Sargent.

Technical Subcommittees:

(a). Wires and Cords: Stranding, identification, types, etc. B. H. Glover, chairman, 207 East Ohio street, Chicago; G. E. Bruen, V. H. Tousley, G. S. Lawler, H. A. Morss, W. S. Clark, W. F. Field.

(b). Cabinets and Cutout Boxes: A. O. Boniface, chairman, 207 East Ohio street, Chicago; E. C. Horton, L. L. Johnson and representative of American Society of Mechanical Engineers.

(c). Outlet Boxes and Covers: E. P. Slack, chairman, 25 City Hall Place, New York; F. D. Varnam, L. A. Barley, H. G. Knoderer.

(d). New 10-Amp. Classification of Fuses: A. R. Small, chairman; W. C. Peet, H. R. Sargent.

3.—Standing Committee on Fixtures, Heaters, Signs and Lamps: J. C. Forsyth, chairman, 123 William street, New York; G. E. Bruen, C. H. Lum.

(a). Heaters: J. C. Forsyth, chairman, 123 William street, New York; I. Osgood, R. B. Shepard, H. J. Mauger, Harold Fulwider, Frank Kuhn, C. J. Killam.

(b). Fixtures and Insulating Joints: J. C. Forsyth, chairman; Emil Anderson, K. W. Adkins, A. Waldschmidt, V. H. Tousley, C. H. Hill, H. S. Wynkeep, Louis McCarty and representatives of the National Fixture Manufacturers' Association.

(c). Incandescent Lamps, Gas-Filled, Use of Lamps in Dusty Places: G. E. Bruen, chairman, 123 William street, New York; F. F. Burroughs, R. P. Strong, W. T. Blackwell.

(d). Extensions from Fixture and Other Outlets: G. E. Bruen, chairman, 123 William street, New York; E. H. Joseph, and representative of Outlet Box Manufacturers.

4.—Standing Committee on Generating and Substations: A. M. Schoen, chairman, Southeastern Underwriters' Association, Atlanta, Ga.; W. H. Blood, K. W. Adkins.

The following topics to be treated by this standing committee: *a*, use of switches between generators and transformers; *b*, revision of rule 1-d on fusing of generator sets.

5.—Standing Committee on Grounding: W. H. Blood, chairman, 147 Milk street, Boston, Mass.; C. M. Goddard, H. S. Wynkoop.

(a). Grounding Motor Frames: W. H. Blood, chairman, G. S. Lawler, W. C. Peet.

The standing committee has under consideration the following topics: *a*, Size of ground wires; *b*, voltage limits for grounding; *c*, omission of grounding for short lengths of conduit, metal raceways, etc.; *d*, minor items of Rules 15 and 15A that relate to grounding.

6.—Standing Committee on Industrial Applications: G. S. Lawler, chairman, 31 Milk street, Boston, Mass.; F. Osgood, C. B. Langdon, J. M. Curtin.

(a). Fuse Protection of Motors: E. E. Turkington, chairman, 31 Milk street, Boston, Mass.; J. C. Forsyth, E. McCleary, W. J. Canada and a representative of the Electric Power Club.

(b). Use of Oil Transformers, Autostarters and Motor-Starting Devices: C. B. Langdon, chairman, 266 Pearl street, Hartford, Conn.; F. O. Evertz, F. A. Barron, T. C. Taliaferro and a representative of the Electric Power Club.

(c). Demand Factors in Wiring: Bassett Jones, chairman, 101 Park avenue, New York; C. H. Hill, A. M. Paddon, A. S. Adams, H. B. Gear.

(d). High Potential Wiring: G. S. Lawler, chairman, 31 Milk street, Boston, Mass.; W. S. Boyd, A. E. Silver, D. W. Roper, C. C. Harbinson.

(e). Use of Enclosed Switches: Washington Devereux, chairman, Bullitt building, Philadelphia; Ben W. C. Clark, H. F. Strickland, P. H. Bartlett and representatives of the Associated Manufacturers of Electrical Supplies and of the Electric Power Club.

(f). Fireproof Switchboard Rooms and Running Mains in Hazardous Rooms, etc.: A. M. Paddon, chairman, Gurney building, Syracuse, N. Y.; C. B. Langdon, W. S. Boyd, E. E. Turkington and C. H. Hill.

(g). Housing of Motors in Dust Places, etc.: F. F. Burroughs, chairman, Mutual Fire Prevention Bureau, Oxford, Mich.; H. W. Hadlock, and representatives of the Electric Power Club and of flour and elevator insurance companies.

(h). Revision of Code Rule No. 88: W. C. Peet, chairman, Peet & Powers, 70 East 45th street, New York; H. S. Wynkoop, R. P. Strong.

(i). Electrical Equipment of Lacquer and Varnishing Rooms: A. C. Hutson, chairman, National Board of Fire Underwriters, 76 William street, New York; O. E. Smith, H. S. Wynkoop.

7.—Standing Committee on Outside Wiring, Building Supply and Services: M. G. Lloyd, chairman, Bureau of Standards, Washington, D. C.; C. H. Hill, F. F. Burroughs. This committee has under consideration the following: *a*, transformer vaults; *b*, location of service conduit near combustible material; *c*, supports for service wires on buildings; *d*, enclosed service switches; *e*, revision of Rule 12-d; *f*, sizes of service wires and use of multiple conductor wire for services.

8.—Standing Committee on Signal Systems: W. S. Boyd, chairman, 175 West Jackson boulevard, Chicago; A. M. Paddon, C. W. Mitchell. This committee with the following will act as subcommittee on revision of Rule 85 of the Code: F. A. Raymond, C. C. Johnson, H. S. Warren, Frank Bean, S. L. Burgher.

9.—Standing Committee on Theaters, Moving Picture Establishments, Places of Public Assembly and Garages: Washington Devereux, chairman, Bullitt building, Philadelphia; V. H. Tousley, C. M. Tait.

(a). Theaters and Moving Picture Wiring Standards: Washington Devereux, chairman; F. A. Barron, B. A. Hanson, C. M. Tait, V. H. Tousley, Joseph Honey, J. C. Moulton.

(b). Exit Light Transformers, low voltage: V. H. Tousley, chairman, City Hall, Chicago; F. A. Barron, B. H. Glover.

(c). Elevator Wiring Standards: Washington Devereux, chairman; W. Doane, C. H. Hill, A. Marks, O. P. Cummings, I. N. Haughton, O. F. Shepard.

(d). Film Rewinders: W. A. Lodge, chairman, 207 East Ohio street, Chicago; L. M. Swaab, F. H. Richardson, Lee Johnson, H. N. Speer.

10.—Standing Committee on Wiring Standards and Systems: W. C. Peet, chairman, Peet & Powers, 70 East 45th street, New York City; Dana Pierce, F. Overbaugh, R. P. Strong.

(a). Conduit Work, Sizes of Wires, Distance Between Pull Boxes, etc.: G. M. Sanborn, chairman, Sanborn Electric Co., Indianapolis, Ind.; A. O. Boniface, John Cole, O. E. Smith.

(b). Wattage Limits for Branch Lighting Circuits: I. Osgood, chairman, 55 Kilby street, Boston Mass.; Bassett Jones, Milton Jones, Albin Gustafson.

(c). Farm Lighting Equipments: Dana Pierce, chairman, 25 City Hall Place, New York; B. H. Glover, C. A. Bates, H. L. Bunting, F. F. Burroughs, W. S. Boyd, C. H. Hill, R. W. E. Moore, R. H. Grant, W. Michaelson, J. E. Cross.

(d). Voltage Limit for Low Potential Systems: W. C. Peet, chairman, Peet & Powers, 70 East 45th street, New York City; H. O. Lacount, H. R. Sargent, C. B. Langdon.

(e). Wiring in Places Subject to High Temperatures: H. S. Wynkoop, chairman, Municipal building, New York City; E. McCleary, R. P. Strong.

(f). Interbuilding Connections: H. S. Wynkoop, chairman, Municipal building, New York City; other members to be appointed.

(g). Extension Wiring in Fireproof Buildings: Committee to be appointed.

"LAND OF THE WONDERFUL LAMP" TO BE ELECTRIFIED.

Chicago's Electrical Show, Oct. 11 to 25, Promises to Be Worth Coming Miles to See.

According to all indications Chicago's Electrical Show, which is to be held at the Coliseum Oct. 11 to 25 inclusive, will surpass any ever held by the electrical interests in this city and will be comparable with those held by this or any other industry any place. More than 80% of the available exhibition space has already been allotted and the elaborate decorative and lighting effects have practically been completed.

The setting of the show was designed in accordance with the most modern ideas in attractive mer-

General View of Decorative Effects and Scheme of Illumination. Planned for Chicago Electrical Show, Oct. 11 to 25.

chandise display and at the same time the scene is destined to leave a lasting impression with all who view it. The setting is Chinese, an exemplification of the electrification of the wonderful Aladdin lamp of fable fame, and the typical oriental colors will dominate. It was designed by W. D'Arcy Ryan and J. W. Gosling of the General Electric Co., Schenectady, N. Y., whose work at the San Francisco's world's fair and many other similar affairs are well known.

In the center of the hall a large Chinese pagoda will be erected. This pagoda will be brilliantly decorated and ornamented by 18,000 "Novagem"

Attractive Poster Being Used to Advertise Chicago's Electric Show.

jewels from the "Tower of Jewels" at San Francisco. Surrounding this pagoda other booths will be arranged in typical Chinese fashion and decorated to fit in with the rest of the setting. A white false ceiling will be placed over the whole, terminating at both ends with drops painted to represent Chinese scenes.

The lighting effects have been especially designed to enhance the general decorative scheme. For local lighting hundreds of imported silk and gauze Chinese and Japanese lanterns, equipped with electric lamps will be used. In addition numerous flood lights and projectors will be installed in the balcony. Modern projectors having a total electric consumption of 32 kw. will play on the jeweled pagoda from all angles. The light from others using a total of 28 kw. will be reflected from the white ceiling upon the entire display and several more will be directed upon the scenic drops. Over all a lighting effect similar to an aurora borealis will be created by a 9-kw. searchlight.

The management of the show, however, has gone further than providing an impressive setting. Special pains have also been taken to make the exhibit itself of interest to visitors. For this reason a representation from all classes of electrical manufacturers has been secured which will include all the latest and best electrical devices and applications. It should therefore prove of interest to industrials as well as laymen and manufacturers should send their electricians, plant superintendents and foremen to the show to see the latest devices developed for transmitting and using electricity.

The usual line of well-known electrical appliances and devices will of course be shown in the latest types and models and in addition, apparatus for heat treating, electric furnaces, electric welding, electric ovens, modern lighting equipment, socket devices, electric tools, reflectors, storage batteries, motors, controllers, electric vehicles, transformers, automatic switches, fuses, wiring devices of all kinds and ventilating equipment will also be exhibited.

The time of the show is also particularly favorable. Although Chicago is known as the convention city there are few periods of like length during the year when as many conventions are held as in the two weeks selected for the show. Among the associations to convene in the city during this time are the Illuminating Engineering Society, Illinois Electrical Contractors Association, Illinois Electrical Association, American Association of Railroad Surgeons, National Dairy Show, Grand Lodge of Illinois A. F. and A. M., National Implement and Vehicle Association, Polish National Council of America, and the Railway Fire Protection Association. Special attention will, of course, be given to the electrical conventions held during this time and in addition efforts will be made to have the delegates at the other conventions attend.

E. W. Lloyd, 72 West Adams street, Chicago is manager of the show.

CIVIL-SERVICE EXAMINATION FOR JUNIOR ELECTRICAL ENGINEER.

Applications for $1080 to $1200 Position Will Be Received Until Further Notice.

The United States Civil Service Commission, Washington, D. C., announces an open competitive examination for junior electrical engineer to fill vacancies in the Bureau of Mines, Department of the Interior, for duty at Pittsburgh, Pa., or elsewhere. The salary is $1080 to $1200 a year, with temporary increase of $240 a year granted by Congress if services are satisfactory. On account of the needs of the service, applications will be received until further notice. Applicants must not have reached their thirtieth birthday on the date of making oath to the application.

Competitors will not be required to report for examination at any place but will be rated on the following subjects: Physical ability, 10; education and experience, 90. Graduation from a four years' course in electrical engineering in a college or university of recognized standing, and at least one year's experience in electrical engineering work outside the college are prerequisites for consideration for this position.

Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission at Washington, D. C., or at one of the district offices.

CHARLES SCHWAB TO ADDRESS MINING AND METALLURGICAL ENGINEERS.

Plans for Annual Convention in Chicago, Sept. 22 to 26, Practically Completed.

Charles Schwab will be a speaker at the banquet of the American Institute of Mining and Metallurgical Engineers to be held in conjunction with its annual convention in Chicago, Sept. 22 to 26 inclusive. Elaborate plans for both the technical and social side of the meeting have been perfected. Engineers who make the trip to Chicago for this meeting are assured of one of the most interesting annual meetings which the Institute has held. In addition to some hundred and fifty papers which have been prepared for the meeting, trips to the zinc smelting districts, the steel works at Gary and the refineries at Whiting and East Chicago are included. A boat trip on the lake together with numerous social events have been arranged for the ladies. The fifth annual exposition of the Chemical Industries will be held in Chicago at the same time as the meeting of the American Institute of Mining and Metallurgical Engineers and members of the Institute are cordially invited to attend.

ELECTRIC VEHICLES TO BE SHOWN AT NEW YORK ELECTRIC SHOW.

The New York Electrical Exposition, which is to be held during the 10 days beginning Sept. 24, at the Grand Central Palace, will have among its exhibits several displays by the leading manufacturers of electric automobiles.

In the commercial car section will be seen different sizes and types of trucks built by the Ward Motor Vehicle Co., the Commercial Truck Co. of America, and the Walker Vehicle Co. Passenger cars will be exhibited by the Baker R & L New York Corporation, and by the Metropolitan Detroit Electric Automobile Co.

Storage-battery manufacturers will be represented by the Electric Storage Battery Co. and the Philadelphia Storage Battery Co.

Another exhibit of particular interest to automobilists will be that of the Bennage Co. This exhibitor will show a new type of electrically heated vulcanizer.

NEW QUARTERS FOR BLIND SCHOOL AT CROCKER-WHEELER WORKS.

The Double Duty Finger Guild of the Crocker-Wheeler Co., Ampere, N. J., an organization for the instruction of the blind that was developed by Dr. Schuyler Skaats Wheeler about two years ago, is arranging to move its headquarters and main workroom now located at North Fifteenth street and Park avenue to a new department in Building No. 70 at the plant. The new quarters will be directly under the restaurant maintained at the works for employes, and a section of this lunch room is to be set aside for the blind workers. This organization, under the direction of Dr. Wheeler, has been highly successful; at the present time about 24 blind workers are engaged in coil work, including taping, insulating, etc., and 10 other blind workers are now being employed in the regular plant with normal workmen after having been instructed at the Guild. Mrs. Ida Hirst Gifford is superintendent of this department.

HOUSEHOLD APPLIANCE CONVENTION HELD IN MINNEAPOLIS.

A convention of the Northwestern Home Appliances Association was held at the Radisson Hotel, Minneapolis, Minn., Aug. 14 to 16. This is an association composed of dealers associated with the Sterling Electric Co. of Minneapolis, the Kelley Hardware Co., of Duluth, and others. Among the manufacturers represented in the association are the United Electric Co., Canton, O., American Ironing Machine Co., Chicago, Pittsburgh Gauge & Supply Co., Pittsburgh, and the Rudd Heater Co.

House Shortage Creates Demand for Service — British Plan for Vehicle Business — Successful Washer Campaign

SCARCITY OF HOUSES CREATES DEMAND FOR ELECTRIC SERVICE.

Georgia Railway & Power Co. Reports Great Activity as the Result of Housing Conditions.

The scarcity of houses that is prevalent throughout the country at present, appears to be particularly evident in Atlanta, Ga. As a result, houses that probably might never have been wired for electric service or piped for gas are getting both these days, and the demand on the contract department of the Georgia Railway & Power Co. is greater than it ever has been at this time of the year, according to W. R. Collier, sales and operating manager.

The demand in that city is so great that people are buying and renting homes for their own use which, under normal circumstances, they would not have been willing to consider. In order to make these homes as comfortable as possible they are being improved by the installation of modern conveniences which naturally includes provisions for the use of gas and electricity. In addition, the owners of buildings wishing to take advantage of this demand and realizing the increased value of their property if equipped for such conveniences, are taking steps to have them installed.

Mr. Collier points out further that there is a large number of new houses being erected and all of these are being provided with both gas and electric service which adds to the company's activity.

ELECTRIC VEHICLE BUSINESS IN ENGLAND.

Electrical Development Director Urges Loaning of Vehicles in Order to Encourage Sales.

J. W. Beauchamp, Director of the British Electrical Development Association, writing in the official organ of the Electric Vehicle Committee, urges electric vehicle manufacturers and electric supply undertakings in England to consider the question of letting out vehicles on trial to possible customers. He says it would not be beyond the resources of some of the central-station companies to offer to possible customers the use of an electric truck with a driver for, say, one month, the vehicle and driver to be entirely at the disposal of the customer for his ordinary cartage business and to be charged and garaged by the central station. At the end of the month the cost of the month's cartage service based on figures for electricity, labor, depreciation, etc., which would be exactly comparable with his own costs if he were to buy the vehicle, would be charged.

Mr. Beauchamp thinks that in many cases it would be found that at the end of the month the customer would be very unwilling to part with the vehicle and the trial would bring home to him as nothing else could the advantages and economy to be achieved in the running of an electric for certain classes of cartage and haulage work. Obviously it would be best to attack the user of horse vans at first and to select cases where considerable loads are conveyed over limited distances. The most effective canvassing consists in the loan of a vehicle with an accomplished and obliging driver who will endeavor to get the best out of it and show to the prospect its full possibilities and advantages.

"Lending vehicles out in this way," says the director, "cannot of course be carried out on an extensive scale unless there are considerable numbers available, but if only one general service lorry were employed for a year on such work, being lent to 10 or 12 different persons and particularly to large organizations in the district, such as municipal undertakings, express and freight companies, coal merchants and general cartage contractors, it would probably result in orders much more quickly than ordinary canvassing and publicity efforts."

Although the possibilities of the latter in relation to the electric vehicle business have been by no means fully explored, Mr. Beauchamp comes to the conclusion that the electric vehicle does its own publicity work very well—that is to say, it may be difficult to induce a large organization to purchase the first one, but when that is accomplished the work is done, and the fleet grows without further canvassing.

MAKING THE WASHING MACHINE CAMPAIGN A SUCCESS.

Two Schemes Used by Eastern Montana Light & Power Co. in Recent Campaign.

Perhaps the most prominent of the electrical devices being advertised and sold at present is the electric washing machine. No doubt the great scarcity of household labor and the growing tendency of the modern American husband to lighten his wife's labors are partly responsible for this, but nevertheless, the clever advertising schemes of the manufacturers and the original efforts of local dealers and central stations, have done much to stimulate this demand.

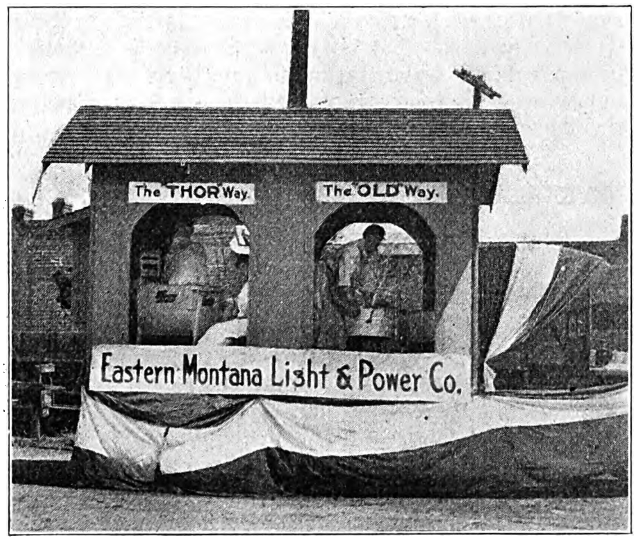
Two such schemes are illustrated herewith. They were used by the Eastern Montana Light and Power Co., Glendive, Mont., of which E. J. Condon of Chicago is president and John M. Culver, sales director, in a recent campaign on Thor electric washers.

In the first scheme, the washer was placed on the roof of the company's building and was illuminated by a number of colored lights placed in the form of an arch above. To add to the effect a number of silk flags were strung from the washer to the arch above which made the effect at night very beautiful. The entire building was also covered with bunting and the show window was attractively decorated with potted ferns and flowers among which smaller electrical appliances were displayed.

The second scheme, which also served to prove the public spiritedness of the company, was a float that took part in a civic parade. On this float a two-room house was built which was suitably decor-

Clever Scheme of Advertising Electric Washers.

ated and arranged so all could see its interior. In one room, called the old way, an old black mammy rubbed over a tub of foaming suds in a vain endeavor to bring the spots out of a soiled garment. In the other room, called "the Thor way," a neatly attired



Central-Station's Float That Won First Prize in Civic Parade.

housewife sat in a rocking chair, reading a magazine, while the electric washer did the work. Needless to say, this float won first prize and also that the campaign proved successful.

LOUISVILLE, KY., CITY HALL GENERATING PLANT ABANDONED.

The City of Louisville, Ky., which for many years has operated an electric generating plant to supply current for the City Hall and annex, has decided to abandon the generation of current and will hereafter purchase its requirements from the Louisville Gas & Electric Co. The business which will be connected by the company soon, amounts to approximately 250 hp.

COMMISSION HOLDS ELECTRIC AND GAS BRANCHES ARE SEPARATE.

New York Commission Also Decides That It Is Time to Consider Situation from Peace Standpoint.

The Public Service Commission of New York, Second District, recently rendered an interesting decision in a complaint against the Central Hudson Gas & Electric Co. Some time ago the commission authorized this company to increase its gas rates from $1.25 to $1.50 per M cu. ft. which resulted in the complaint being filed by residents of Poughkeepsie and Newburgh. Evidence was taken at the critical period of the war and the Commission was reluctant to determine a rate on evidence or conditions at that time. Representatives of the Poughkeepsie complainants desired that the investigation include electrical operations, on the theory that the price of gas should not be increased even if the gas operations should be found unprofitable provided the company as a whole was earning a fair return. Commissioner Irvine declined to receive the evidence on the ground that the two branches of the business must be considered separately and that electric consumers could not be required to make up a loss on the gas business. In a memorandum of the Commission he says doubt was expressed on this point and a case was pending demanding its judicial determination. This case was decided in accordance with the theory expressed by Commissioner Irvine.

The Poughkeepsie complainants were informed that there was no complaint against the company's electric rates, but if one were filed, as provided by the statute, the two matters would be disposed of at the same time. No complaint was filed.

Commissioner Irvine, in reviewing the evidence presented, said:

"An estimate of operating results for 1919 involves too many elements of conjecture to render it of much service. There is nothing to indicate a substantial addition to revenue. It is to be hoped and only hoped that expenses may decrease. It is not probable that the return can exceed 7%. During the war the Commission was inclined when rate adjustments became necessary, to permit increases only far enough to meet operating expenses, taxes and interest on bonds or, in other words, merely to insure solvency. The time has now come when we may properly consider a fair peace time return on the investment. It is necessary to do so if utilities are to be preserved and capital invited in order to make extensions and betterments essential to the rendition of proper service. A return of 7% or less can not be considered an unduly large return. It may be that coal prices and oil prices, and perhaps some other elements of cost, will soon decrease to such an extent as to warrant a lower rate. On the figures before us we cannot hold that the present rate is at the present time unreasonably high and the complaints must, therefore, be dismissed, but the current schedule should not be fixed for a period longer than one year. It is true that the corporation has been paying dividends during the two years under special examination of 8% and that in 1918 the corporate surplus was increased by the amount of $5524. This indicates higher earnings on the electrical side than on the gas side, but, for reasons already stated, the electrical operations are not before the Commission, and therefore no opinion is expressed or even entertained as to the reasonableness of the electric rates."

Operating Practice

Leaky Rock-Filled Dams — Manhole Ladders in Cleveland — Operating Results with Mechanical Soot Blowers

DETECTING AND REMEDYING LEAKY ROCK-FILLED DAMS.

Simple Expedients to Be Followed—Precautions to Be Observed.

By W. F. Snyder.

There are numerous hydroelectric plants and mills, principally in the smaller installations, in which the leakage through rock-filled timber dams assumes such proportions that it materially decreases the amount of power available. The dams of this type of construction are usually sheeted on the upstream side and after a while the sheeting deteriorates and the water passes through in ever increasing volume. Ordinarily this is of no great consequence for it can be resheeted. If, however, the sheeting was not carefully driven to hard pan or solid rock there might be serious undermining of the dam. The action of undermining varies according to the nature of the soil upon which it is built. If it is rock the chances are that the leakage will deteriorate the sheeting. If it is hard pan it will cut through it if the sheeting is not driven deep enough to overcome the pressure.

In gravel or loose soil it is imperative that the sheeting be driven deep enough so as to prevent all leakage, for a small leak will rapidly increase. If in clay, the sheeting driven into it for a moderate depth will very seldom give trouble. Concrete dams should always be on rock or hard pan and if on the latter an extra trench with a double row of sheet piling driven in it will prevent all leakage.

These leakage troubles do not always originate at the dam. Sometimes they are hundreds of feet back and are very hard to locate. If the water is reasonably clear and the pond not too deep, the easiest way to find these leaks is to use a boat to which are fastened ropes on each end and extending across the pond. Two men, one on each shore, move the boat back and forth, shifting position each time by 6 or 8 ft. up or down stream, as the case may be, so that the bottom may be carefully explored. In the boat a storage battery of the automobile type supplies energy to an automobile lamp which is fastened to a pole located inside a tin can so as to direct the light downward and keep it out of the eyes of the operator and enable him to observe the bottom. Care must be taken that the wires to the battery will easily detach themselves for there is danger of the boat being overturned if the light should be drawn into a suck hole suddenly. Sometimes these holes are of such magnitude that they can be observed by the whirlpool action on the water. Any exploring with lamps must be conducted after dark.

If the water is turbid and it is not possible to see very far, a metallic tube resembling a telescope, tapering from 2 to 6 or 8 in. in a length of 6 to 8 ft., tightly closed off at the bottom with plate glass, will enable observations to be made. To this tube the light can be fastened with the rays directed downward as before. It will be necessary to fasten lead or similar weight to the tube so as to make it sink to the proper depth. Great care must be observed so that the tube will not be caught in the suck hole, otherwise it will be gone in an instant.

Another way to explore the bottom is to proceed with a pole to which is fastened a can, the drawing action of which will locate the suck hole. After the suck hole is located, a few 2 by 4-in. timbers or poles can be placed in the shape of a tripod and the telescope attached and then placed over the hole for observation.

The hole being located and the size and nature thereof being determined, the next move is to plug it up. Sometimes throwing rocks in which will be carried down a distance and become lodged suffices. Some may pass through and come out below. A few corked bottles or sealed tin cans forced in above will often reveal the outlet below, after which bags of cinders, sand and stones may be thrown in the hole while someone observes the point of discharge to see if these bags are coming through. If they are not seen to come through it is assumed that they have lodged. It may be well to prove this by trying more cans or bottles and also looking for a decrease in the suction of the hole. If it is determined that the material is lodging, follow up quickly with more bags of cinders and stones until the suction is nearly gone. Then it is well to quickly fill with cinders and manure or just spout fine cinders in the hole. Care must be taken that about 2 ft. is left for a concrete top to seal this so as to avoid further trouble. The concrete should be one part cement to two parts sand, well mixed and slightly wet. This should be spouted into position through a pipe and be permitted to spread over twice as much area as that of the hole so as to be sure that everything is sealed.

Similar methods can also be used when the leak is at the dam proper. There are many leaks such as described which if repaired would result in the delivery of much more power. It is often advisable to engage an expert at hydraulic work to attend to work of this nature for he will usually save money in the long run.

MANHOLE LADDER PROTECTS CABLE SHEATHS.

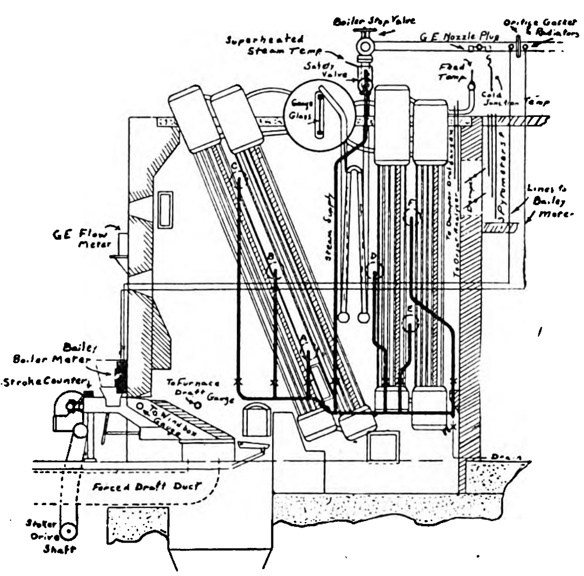
Cleveland Electric Illuminating Co. Uses Ladders in Its Manholes.

Damage is frequently done to underground cables where they pass through the manholes. This damage, which occurs to the lead sheath, is done by the men using the cables as steps to move in and out of the manholes and as they work in the manhole. Even when care is taken a cable sheath may easily be damaged irreparably by a nail in a man's shoe and similar causes.

The use of cement coverings, a sheath of steel banding or asbestos cloth, are methods of protecting the comparatively soft lead cable sheaths, but even with these a careless or hasty man using the cables as steps may do damage. The Cleveland Electric Illuminating Co. is using a galvanized ladder in its manholes by which the men enter and leave the manholes. The company is finding these ladders worth while, since not only do they reduce the likelihood of cable trouble but lessen the chance of accident to the men and loss of time incident to climbing in and out of the manholes over the cables.

OPERATING RESULTS OBTAINED BY USE OF MECHANICAL SOOT BLOWERS.

The economies effected by the use of mechanical soot blowers, due to reduction in quantity of coal required, increased boiler efficiency and increased steaming capacity, have been generally recognized by engineers in recent years. Owing to inherent difficulties, however, there have been very few detailed tests made. The following list of mechanical soot blowers, thought to be the most accurate yet carried out, was made in



a boiler room comprising 14 Bigelow-Hornsby boilers of 625 b-hp. equipped with Diamond soot blowers and fired by Taylor stokers.

The boiler selected for the test consisted of ten groups or units of inclined tubes in the front over the furnace, and ten groups of vertical tubes in the back of these with vertical type Foster superheater in between. Each group or unit of tubes contains 21 3¼-in. steel tubes, a total of 420 tubes. All tubes fit into so-called unit drums. In each of these the ten top drums are connected to the main cross drum. The total heating surface of boiler is 7322 sq. ft. Manufacturer's rating is 625 b-hp. Steam pressure and safety valve setting are similar to that on the B. & W. boilers.

The stoker is of the Taylor seven retort underfeed type, having a grate area of 105 sq. ft. inclined grate. Forced draft was supplied to this stoker by a turbine-driven multivane double inlet fans. In this test the forced draft and stoker driver were separated and stoker was driven by one of the Westinghouse engines recently installed on the boiler room floor for the driving of stokers. Induced draft was obtained by means of fans located at the uptake to the stack.

The soot blowing equipment on this boiler consists of six elements located as shown in Fig. 2. The perforations in the elements A, C D, and F are arranged in five groups of four holes each on one side of the pipe, and five groups of two holes each on the opposite side of the pipe. The elements are set so that the issuing streams of live steam will play all along the tubes. Element B has a set of evenly spaced holes on one side only. This is essentially a baffle blowing element and the stop with which it is equipped prevents the hand wheel from being turned to a position where the jets will play directly on the baffle to the detriment of the latter. Superheated steam is used on this boiler, the supply being taken from the point in the boiler outlet just before the main valve.

The steam flow was obtained by means of two meters, one an integrating recording indicating General Electric meter, already installed and used in tests, the other a newly installed Bailey boiler meter. Weight of coal was obtained from the traveling weigh hoppers and lorry tickets. A revolution counter was placed on the Taylor stoker to count the revolutions of the main power shaft. The thermometer for obtaining superheated steam temperature and that for obtaining feed-water temperature were placed in thermometer wells in their respective pipes at the top of the boiler as in previous tests. The uptake temperature was obtained from three pyrometers inserted into the flue above the damper and inserted at 4, 5 or 6 ft., respectively. The cold junction temperature was obtained by means of an indicating thermometer suspended over the cold junction of the pyrometers, steam pressure was obtained from the steam gauge in regular service on the drum. A steam correcting thermometer for obtaining the superheated steam temperature corrected. The carbon dioxide of flue gas was obtained by means of a sampling tube already installed and used in previous tests in conjunction with a standard Orsat gas analyzer. Draft over the furnace and at the damper was obtained on the indicated gauge. Pressure in the wind box was indicated on the lower gauge and on the recording pressure gauge. In addition to the above, the Bailey meter indicated the draft over the furnace and the air flow through the boiler, the latter being obtained by means of two 1½-in. pipe connections, one to the combustion chamber over the furnace and the other in front of the damper at the same height as the first. The various items indicated above and constituting the testing apparatus on this boiler, are shown in the accompanying sketch.

The test began at 5 a. m., Feb. 3, 1919. The duration of each run was 24 hours. At the beginning of each run the fire was cleaned and the hopper filled. The tail gate was cleaned whenever found necessary by observation of the fire. This varied from about every 2 to 4 hours, depending on the load.

The method was to run a series of tests with the soot blowers attempting to grade the runs from 75% load to about 200% load, each run to extend for 24 hours. This was to be followed immediately without operating the soot blowers, duplicating the loads and conditions of the first series as closely as possible.

The fire-room crew were guided by the steam-flow meter in maintaining the load and also by regulating the opening at the dampers on other boilers. During the test, with soot blowers, the latter were operated every 6 hours. The operation consisted of turning on the steam in the supply header, then in turning on the steam in each element and by means of the chain around the hand wheel turning the element three times in both directions as far as possible. This operation for the boiler occupied 10 and 15 minutes.

On this boiler eight runs in all were made, the first four being with soot blowers and the second four being without soot blowers, attempting to reproduce the conditions of the first four as nearly as possible. In doing this the fire-room crew and the tester were guided by the average conditions attained in the first four runs. Readings were taken every 20 minutes.

The steam utilized by the soot blowers was not registered by the steam flow meters, owing to the fact that the meter connections to the boiler are placed at a point which is not passed by the steam used in the soot blowers. The steam was used along the inside walls and bridgewall to decrease the accumulation and adhesion of clinker. This is a connection in operation during regular operation, and was less so during the test. This steam, also, was not taken into account by the steam flow meter. Readings were taken as follows: Steam flow; air flow; furnace draft gauge; windbox pressure; the speed of the stoker line shaft; the number of revolutions of the stoker power shaft; steam temperature; feed water temperature; flue gas temperature on three pyrometers; cold junction temperature; air temperature; steam pressure, and carbon dioxide in the flue gas. Forced draft was obtained from a blower which was isolated from the other blowers by closing the division damper. It was kept running throughout the entire test, and the draft on the boiler was regulated by means of the control at the boiler.

It has been stated previously that with the present practice of cleaning the boilers with the hand lance, each boiler is cleaned every four or five days. In the tests without soot blowers, in order to reduce this condition, the series was started with the boiler heating surface clean and then left without any cleaning during the series. If the series had been extended for, say, an equal period or longer, and if during that time the regular hand method had been used to clean the boilers on the regular schedule, it is very probable that a still greater rise in flue gas temperature and still greater decrease in combined efficiency would have resulted. This statement is made because it is believed that with the present hand method, owing to the fact that all soot is not removed, there is a gradual accumulation on the heating surface, the longer the boiler remains in service. Therefore, based on the above, it is safe to say that the results obtained were conservative, that a more exact test along the line indicated would show better results.

In addition to the above, may be mentioned the fact that operation of the soot blowers does not require the banking or shutting down of the boiler, while in order to remove the soot by hand method it is necessary to shut down the boiler for two or three hours, during which time the boiler setting cools and must be warmed up again. Here is a loss which is eliminated by the use of soot blowers.

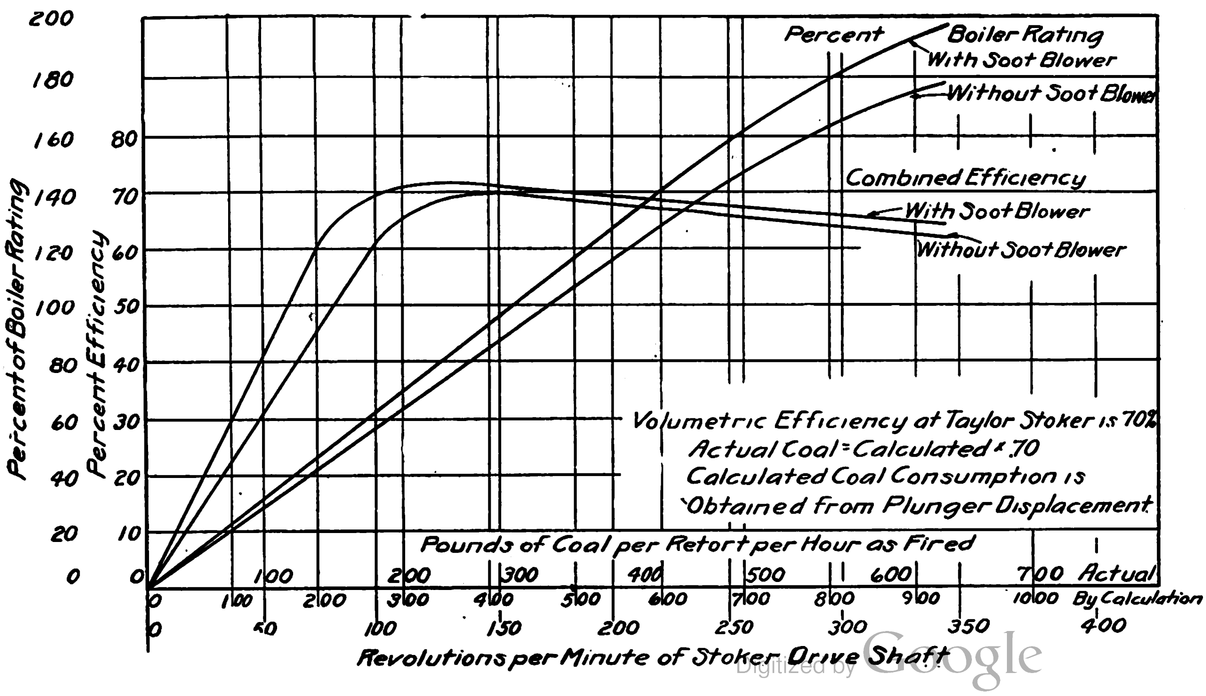
It has been stated that the steam used by the soot blowers was not included in computing boiler efficiency. In other words the boiler was charged with this steam. On the other hand since no steam was used in the tests without soot blowers, the boiler was not charged with steam for this purpose, but it is equivalent that in a long series, as in actual practice, considerable steam would be used for cleaning by hand lance, which would have to be charged to the boiler, therefore further decreasing the combined efficiency.

In conclusion it should be noted that these tests were conducted in a manner calculated to indicate a minimum rather than a maximum improvement by the use of soot blowers. It would have been fairer, on the whole, perhaps, to have refrained from using the soot blowers at all before making the tests without soot blowers, using the hand lance only to clean the boilers at the regular periods of cleaning. Had this been done, the boilers would not have had the advantage of being thoroughly cleaned by mechanical blowers when they entered the hand hose test.

Comparison of Composite Results with and without Diamond Soot Blowers.

Decrease in average uptake temperature with soot blowers	36.1%
Percentage gain in efficiency of boiler, furnace and grate with soot blowers	2.05%
Value of savings of coal per year based on 1918 consumption and prices	$8,559.86

The accompanying table contains a summary of the benefits, exclusive of decreased labor and labor turn-over, of using the soot blowers. It shows that even under the conditions given, the soot blowers would pay for themselves in a comparatively short time.



Contractor-Dealer

How Turnover Effects Profits—Clever Schemes Used to Attract Summer Trade—Dealer's Relations to the Public

THE EFFECTS OF TURNOVER ON PROFITS.

A Discussion of This Important Factor in Merchandising and Methods of Figuring.

By Chester A. Gauss.

Everyone knows that a high rate of turnover is desirable but the reason is often obscure. In fact, the difference between a quick turnover and a slow turnover often amounts to the difference between success and failure.

Turnover may be said to be the time that elapses between the time an article is paid for and the time it is turned over into money again. It is hence, the length of time money is invested in any given lot of merchandise. A good paying business can be built upon small profits just as well as upon large profits. It all depends upon the rate of turnover. Some United Cigar Stores have turned over their stock as often as fifty times a year. A net profit of 1% at such a turnover rate would give a profit of 50% on the capital invested at the end of the year. If the turnover were only 25 times a year and the net profit 1% on sales, the profit for the year on the capital invested would be 25%. To realize the same profit on this turnover as on a turnover 50 times a year, the net profit per sale would have to be increased to 2%.

It is not likely that any electrical contractor or dealer can realize such rapid turnovers but the same principle holds. If a contractor-dealer buys an appliance for $5 and sells it for $15 at the end of the year he has made 200% gross profit on his investment. If he buys $5 worth of electric lamps per month and sells this amount of lamps each month for $7.50, he realizes a gross profit of 50% per month on his investment. This amounts to 50 times 12 or 600% profit for the year on the investment. In other words at these turnovers $5 invested in the appliance first referred to gives a gross profit of $10 at the end of the year while $5 invested in lamps gives a gross profit of $30 at the end of the year.

The profit in any business is, therefore, in the sale of goods and not in the keeping of the merchandise. The more sales that are made in a given time, the more rapidly the stock is turned over and the greater the profit. If an electrical contractor-dealer finds that he cannot sell certain stock at a profit, it is better to sell it at a loss, thus releasing the capital invested in it so that it can be reinvested in stock that will sell quickly and earn money for him.

For the man with small capital, goods that sell quickly should be bought in preference to the slow sellers. It is far easier to show a good profit at the end of the year by doing this than by loading a store up with goods upon which the turnover is slow. Limited capital should always be kept working.

Turnover can only be bettered by proper buying or the increasing of sales. Goods cannot be bought properly unless some record is kept of the sales of each article. To obtain this information, of course, involves a little labor but, since it enables the merchant to sell the same volume on a smaller capital investment, it pays.

One of the easiest ways to obtain data on turnover is to maintain a card index with cards for each article carried. On these cards should be entered the date and quantity of an order of goods when received, as well as the quantity still on hand at that time. When the stock on hand of any item becomes low the merchant can easily count the amount on hand and by referring to the card determine the rate of turnover on the last lot—that is, how long it took to dispose of it. This will enable him to determine the best quantity to order.

When ordering, discounts play as important a part in determining the quantity as does turnover. Suppose that by buying lamps in 100 lots no discount will be obtained and the stock turned over in a month, while if 500 lamps are bought a 10% discount will be obtained. On the basis mentioned, it would take five months to turn over this stock of 500 lamps. If the net profit per lamp is 20% of the cost price when bought in 100 lots, the profit at the end of the year on the money invested will be 12 times 20 or 240%. If the lamps are bought 500 at a time and sold at the same price 10% additional profit will be made on the cost price or a total of 30%. But the 500 lot stock can only be turned over in 5 months or 2 2/5 times a year. The profit for the year on the money invested will be 30 times 2 2/5 or 72%, compared with 240% profit on the invested capital if the lamps are bought in 100 lots. It would, hence, pay the electrical contractor-dealer who is limited in capital to buy in the smaller quantity.

Suppose, however, that the electrical contractor dealer is not limited in capital and that 100 lamps cost him $25. On this basis 500 lamps cost him $112.50. At the end of the year he will make 240% profit on $25 or $60, which is 72% profit, while on $112.50 the gross profit amounts to $81. Since this electrical contractor dealer has unlimited capital it would be well for him to buy in 500 lots and obtain this $21 additional profit on his investment.

Overhead and turnover are closely related although it is not an infrequent occurrence for one to fail to realize the importance of the connection. If, by spending $100 a year in advertising a merchant can double his turnover on an article which he buys in $100 lots and turns over for $150 once every two months it will pay him to do so. Without advertising he would realize 6 times $50 or $300 per year on an investment of $100. If he spends $100 a year in advertising and is thus able to turn over this $100 stock once a month, he will have realized 12 times $50 or $600 per year on his $100 invested in merchandise. From this $600 profit should be deducted the $100 spent for advertising, leaving a net profit of $500 on the investment in place of $300 as would be the case if no advertising were done.

Similarly, if a $20 a week clerk can sell one washer costing $75 and selling at $125 a month while a $25 a week clerk can sell two washers per month, it will pay to fire the $20 a week clerk and hire a $25 a week clerk provided, of course, he is as efficient or more efficient than the cheaper clerk in selling other appliances. Considering four weeks to a month, the higher priced clerk costs only $20 more but in place of selling one washer at $50 profit he has sold two which give a profit of $100.

In figuring turnover one must also take into consideration the effect of any increase or decrease in his turnover upon his overhead expense. If doubling the rate of turnover means that double the sales can be made at the same overhead expense, all the advantages of doubling represent clear profit. If, however, doubling the turnover adds to the overhead expense, this increased overhead must be figured in when determining the desirability of the increased turnover.

Another factor that is too often overlooked in connection with turnover is collections. An article is really not turned over until the selling price is actually paid by a customer. If collections are difficult and if credit, where granted, must be long time credit, it may pay the electrical contractor dealer to sacrifice this credit trade because it takes so long to realize on his investment that, if the same amount were invested in other goods and a strict cash business done, the amount realized at the end of the year may be greater.

Prices and turnover also are closely connected. One can more easily afford to make a small profit on goods that turn over rapidly than to make a small profit on goods that turn over slowly. A profit of 1% on an investment that turns over 12 times a year amounts to the same at the end of the year as 12% on the same amount invested in articles that turn over only once a year.

From this, one can readily see that if a merchant can make his turnover more rapid by sacrificing a little net profit on each sale it may be possible to make more money on the same investment at the end of the year. If an article costing 20 cents is sold at 30 cents, and the stock of 250 worth $50 is turned over once every two months, the gross profit at the end of the year neglecting overhead is 250 times 10 cents times 6 to $150. If sold at 28 cents and turned over once a month the gross profit at the end of the year will be 250 times 8 times 12 or $240 on the investment.

These are but a few factors that affect the profits at the end of the year. Every innovation and every change made in methods, policies, buying, etc., must be viewed from many angles—overhead, net profit per sale, turnover, etc., in order to determine its effect upon the profits on the capital invested.

FEATURING ELECTRICAL HOUSEHOLD SUPPLIES DURING SUMMER WEATHER.

Several Clever Schemes Used by Successful Merchants to Attract Summer Trade.

By W. B. Stoddard.

Although the hot summer weather is nearly over there will still be many days when the thought of cooking becomes a nightmare to the majority of housewives. This is the time to impress upon them the fact that many crisp, dainty and appetizing meals can be prepared without heating up the house by using electricity and electric cooking utensils. E. L. Knight & Co., Portland, Ore., instituted a regular campaign along this line by means of catchy cards in the papers, such as:

What Shall We Have for Breakfast?

Coffee, and toast, and a poached egg, with a dish of fruit. Save time and temper, and serve them in a cool room.

It's regular fun to get breakfast with an Electric Toaster, Percolator and Hot Water Heater. No need to go into the kitchen at all—make them and serve them at the dining room table.

Another advertisement laid stress on the convenience for mid-day or after-theater lunch:

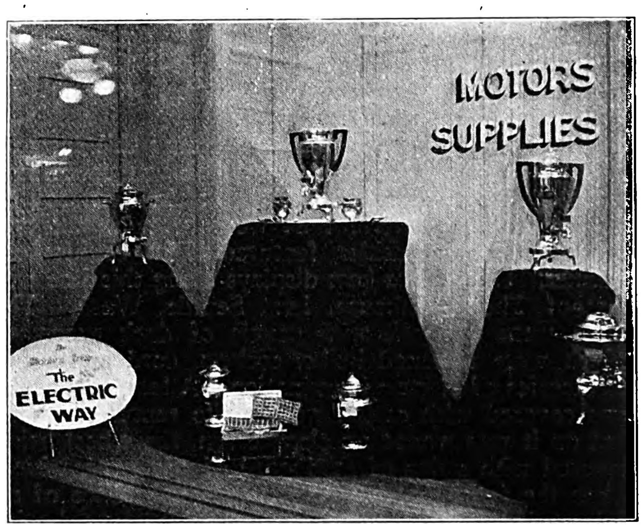
A Tasty Little Midnight Feast.

Whether the weather is hot or cold, a cup of tea, chocolate or coffee is the best thing for that "tired feeling" that is the result of a strenuous day's activity. Crisp toast, too, to go with the salad for a noon-day lunch is always acceptable.

But who wants to make a hot fire to secure these little luxuries? No need to heat the room or yourself. Use an Electric Percolator, Toaster or Grill, and earn the enthusiastic praise of your luncheon companions.

The window that supplemented these cards attracted instant attention. Three tall stands were draped with folds of velvet, and on top of each was an electric percolator. Two lower stands held chafing dishes, and down in front was a waffle-iron with three or four crisp, brown waffles. A large oval card advised: "The Modern Way—the Electric Way." When the idea of a more general use for electric appliances had been thoroughly spread, they sent out to a selected list of patrons a card of invitation:

"You are cordially invited to attend our afternoon tea, Saturday afternoon, from 2 to 5, and learn what delicious lunches can be prepared on electric appliances. Come and enjoy a cup of tea."



An Attractive Window Display of Electric Cooking Appliances.

A little rustic summer house was fitted up at one side of the store and in this sat a young woman before a tea table, on which was a large electric percolator, toaster and grill. Upon these she made coffee, tea, toast and a dressing for the toast. This was served by a maid to all callers, wicker chairs and small tables being disposed about the salesroom so that all could enjoy the lunch at their leisure. "We found," said the manager, "that by putting our guests thoroughly at their ease the best results were secured. By having them seated, too, their gaze had a chance to wander around the store, and, as we took pains to see that all of our appliances were arranged in the most attractive manner possible, many conveniences were seen that caught their fancy. We were not too high-brow to refrain from tagging each piece of merchandise, though in an inconspicuous manner of course, and the result was that they had a chance to learn the price without consulting any of the sales

A Fan Display That Suggests Cooling Breezes.

force, which many seem afraid to do." Little wicker tables were distributed about the room, each with a table lamp with wicker, silk-lined shade, and a vase of flowers. These were set with fragile china and the appropriate electrical appliances, and each table bore an appropriate card.

For the benefit of many, especially men who stopped to look at the window without going inside, there was a small metal wall pocket attached to the bricks at the side of the window, which had printed above it: "Take One of Each." In this pocket, which was divided into compartments, were little booklets on mazda lamps, household appliances, washing machines and house wiring.

The hot weather was long in coming this summer but when it came it set upon us with a vengeance, and the thoughts of all were turning to the best way of keeping cool. Electric fans were brought out and every wideawake dealer featured them in his best manner. One of the best displays along this line was that of The Lighthouse, Inc., Seattle, Wash. The walls were of buff, with panels of dark green, to which were fastened bulbs, sockets, cord and other accessories of electric illumination. A long low bench was covered with cotton wadding to represent snow, and on it was placed an electric fan, the wheel being covered with strips of cardboard of gay hues, which, when the fan revolved, gave it the appearance of an animated rainbow. The floor was also covered with cotton, amid which was an electric fan at rest, so that one could observe its construction.

But it is not only in the drawing room and dining room that electricity comes to one's aid. The laundry will benefit immensely by its use, and especially in the rural districts, where the housewife is usually the laundress as well. The electric washer will prevent many a nervous breakdown. H. R. Basford, San Francisco, brought this fact pertinently before the public through his publicity campaign.

In the window was a scene that showed the contrast very strongly. At one side was the figure of a woman in water-splashed dress and apron, bending over a tub, set on the back of a chair, and at the other an electric washing machine, and near it, in a wicker chair, reading a paper, another woman in neat blue dress. Cards at the base of either figure said: "The Old Way" and "The New Way." Across the base of the window extended a long sign: "Buy an Electric Washing Machine and turn Blue Monday into Sunny Monday." His newspaper advertisement read:

STOP! MR. MAN!

You don't cut wheat with a scythe. You don't write with a quill. You don't read by a tallow candle.

WHY DO YOU EXPECT YOUR WIFE TO USE THE OLD-FASHIONED WASH TUB?

Bring the good wife down to our store and let us demonstrate the Electric Washing Machine. A week's wash done in an hour.

Sold on easy terms if you desire. Pays for itself in a year's time in saving on wear of clothes and laundress' time.

During the recent Home Coming Week celebration they created much amusement, but at the same time drove home very effectively the point they wished to make. During this festival a float was arranged on one end of which was a man, enveloped in a big apron, laboriously scrubbing clothes, while at the other his little daughter was superintending the washing of clothes in an electric washing machine. A big sign on either side of the float observed: "If Father had to do the washing you'd see an Electric Washing Machine in every home inside of a month. Be a good sport and get one for the good wife. Sold on easy terms if desired. Come in and see them demonstrated."

DEALER'S RELATION TO THE PUBLIC IN MERCHANDISING.

Paper Read Before National Association of Electric Contractors and Dealers at Recent Convention.

BY J. R. TOMLINSON

Pierce-Tomlinson Electric Co., Portland, Ore.

The relations of the dealer to the public in merchandising consists of two distinct fundamental factors that must be analyzed and studied separately to determine whether the electrical retail store in its present relation to the public is to continue and develop along lines now existing and the proposed development thereof, or whether it is to change its course into some other channel.

The first of these factors is,—does the present retailer stand on logical, economic ground as a constituent part of the machinery by which electrical goods are to be distributed to the general public? From a theoretical viewpoint the retailer as we know him at present, is surely the proper agency through which the manufacturers' product should flow to reach the consumer, but whether or not he will be so recognized in the future depends upon how he develops as a business man. Now that the world has again resumed something like a normal attitude, manufacturers are turning their thoughts and energies to supplying the needs of the people that will contribute to their comfort and pleasure instead of their destruction and the dealer must, to be recognized as the logical distributor of such goods, be able to convince the manufacturers that he can furnish the business vehicle for such service. Competition is going to be very keen and the manufacturer will seek the outlet through which he can distribute the greatest quantity of his product, therefore it will be incumbent upon the dealer to convince the manufacturer that he is equipped in every essential detail, such as adequate finance, energetic sales policy, efficient delivery service and a liberal repair service. This is the first fundamental to be established. Having satisfied the manufacturer as to the tenability of his position, the second fundamental must be considered—contact with the public.

From the standpoint of economy, is a line of electrical specialty stores prepared to dispense strictly electrical apparatus and supplies, justifiable or shall this business be absorbed by other merchants? Again, due to the fact that the business is of a highly technical nature, it is evident that the public would be much more efficiently and satisfactorily served if a sufficient number of electrical specialty stores judiciously distributed and wisely operated, were to be established.

In any discussion of the relationship of the dealer to the public it would seem that the first consideration should be a clear understanding of just what constitutes the dealer. According to Webster, "The dealer is one who deals in any sense—a trader." However, the more modern classification of dealer in the term "Merchandiser" is preferable. According to Webster, the merchandiser is a person who buys and sells commodities as a business for profit. This distinction is made because it can readily be appreciated that we have too many "dealers" in this country and not enough "merchandisers."

Men and women of this country take the store and the merchandiser too much as a matter of fact, just as they take electric service with scarcely a thought of its wonders and its possibilities. After the house in which he lives, nothing is more important to man in the economy of life than the store from which he draws those things upon which he lives.

Thus the storekeeper or the merchandiser, is one of the greatest factors in the economy of life. Upon his efficiency depends the economical distribution of nearly everything that man produces. He is not alone the most important link in the chain of distribution that reaches from producer to consumer,—he is, practically the whole chain.

In improving the efficiency of the storekeeper, therefore, one serves the manufacturer and other producers by stimulating the consumption of their commodities. And, in like manner, the general public is served by every improvement in service and economical distribution. A merchandiser who loafs on his job not only limits his own livelihood but is an encumbrance to the prosperity of his fellow men.

In order to justify his existence as such, the electrical specialty merchandiser must, in addition to being competent to give expert information to his customer on ordinary, every-day electrical problems, be a competent business executive. All these accomplishments are not essentially to be centered in the one individual where the establishment is large, but in the smaller cities where the proprietor personally supervises the detailed affairs of his business he must necessarily, to be successful, be both executive and experienced mechanic. For this reason some plan should be devised whereby the electrical dealer of the future may receive his preliminary instruction in th art of merchandising. A large percentage of the present dealers are men who have stepped into the business from the ranks of the mechanics without having had any previous preparation for executive or merchandising service. The results of this are well known. This situation should be rectified for the good of the vocation and the public. To establish the fact that he occupies a sound economic position, the dealer must keep absolutely abreast of the times in the realm of merchandising.

In going deeper into the relations of the merchandiser to the public, there is one very important factor to consider, that is the element of human nature. Human nature is largely the same the country over. The desire to possess necessaries and luxuries exists in every man, woman and child. Therefore, whether the merchandiser be located in a large city, or a small town, the first milestone on the road to success is a study of human nature, particularly of the buying characteristics of your community.

Truth in advertising should be an unwavering principle, and advertising matter, systematically placed, should always be clearly and unmistakably worded so that the reader may have no cause to misconstrue the meaning.

The store arrangement and display should be orderly and tidy, the quality of the furnishings depending largely upon the class of trade that is catered to, and the general character of the surroundings, but always neat and clean. Show windows should be washed frequently and the window display should be changed at least every two weeks. If the many excellent and timely suggestions that are received by all dealers through the mails almost daily from the various manufacturers, and trade papers, are preserved for use at appropriate seasons, there would be no excuse for paucity of window-dressing ideas.

Neat tags, bearing retail prices in plain figures, should be appended to each article for sale. This gives the customer a feeling of confidence that he is dealing with a one-price concern.

The sales force should be neatly attired, courteous and accommodating. Most customers have absolutely no knowledge of electrical terms or their meaning, and the manner in which the salesman imparts a little helpful information to such customers usually determines whether or not he has made a future patron. If the information desired is given in a friendly, helpful spirit—well and good, but if with a lordly, smarter-than-thou air—good-bye customer. In fact, in all departments of his business through which he comes in contact with the public, such as his accounting and collections, delivery and repair service, good judgment must be exercised if the best results are to be obtained.

A liberal repair service to remedy or repair defective goods is a good policy. Occasionally, some one will take advantage of such liberality, but in the long run it pays.

One excellent opportunity for widening his clientele is quite generally overlooked by the electrical dealer. That is through membership and active participation in the activities of his local chamber of commerce, or other civic organizations. Most people are appreciative of unselfish efforts that are made in behalf of their home town and if the dealer does his fair share of community work he will find in addition to the personal satisfaction arising from having performed some real duties of our citizenship that there will come a response from his neighbors and townspeople in the form of increased business that will be a surprise to him. In addition, all transactions, whether private or public, should be so conducted as to inspire in the public mind a feeling of absolute confidence and trust.

In conclusion, the measure of the merchant's success will depend upon his ability to qualify on the foregoing necessary conditions, and if he puts industry behind it all he need have no fear for the public's hearty support. In fact, no opportunity exists in the retail line today that seems so favorable for men of the right qualifications.

New Appliances

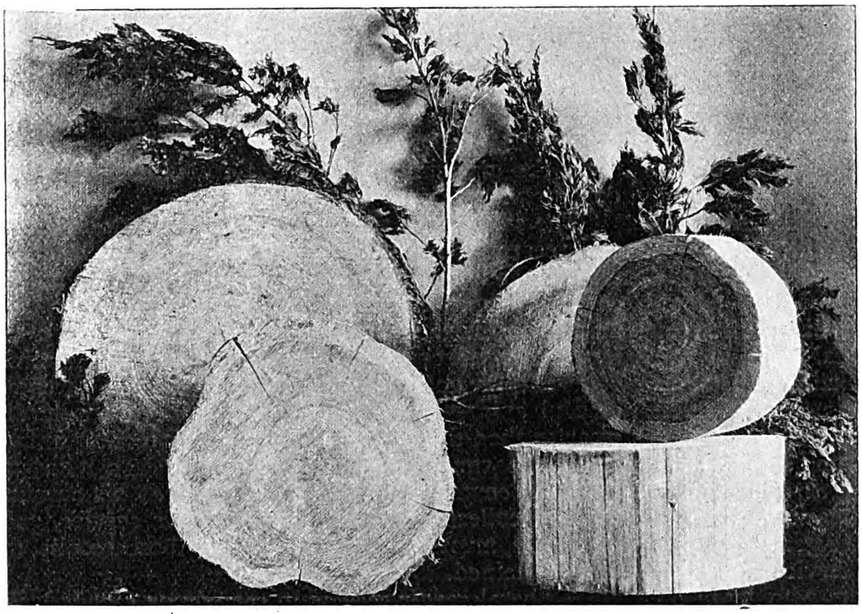
Southern White Cedar for Poles—Special Radio Apparatus for Experimenters — Single-Stage Centrifugal Pumps

Southern White Cedar for Overhead Line Poles.

Cedar has for a great many years been a favored timber for poles of electric light, power, telephone and telegraph companies, the reasons for its choice being its well-known properties of long life, strength and reliability of service. Among the cedars is a species that has not yet been generally employed to any great extent except in certain sections of the country. It is southern white cedar. A Forestry Service bulletin states it is valuable "on account of its long life when in contact with the ground." There are instances of southern white cedar poles having been set for 20 years and still remaining in serviceable condition. One of these lines is at Marion, Ohio.

An experienced timber producer not long ago became a convert to the suitability of southern white cedar for pole purposes and has actively taken up its production and sale for this and other purposes. Willis H. Gilbert, Fisher building, Chicago, has taken over the business of handling "Dixie" brand white cedar. He has had an extended experience in the lumber business since 1880, when he operated pine and hardwood mills at Bay City, Mich. In 1896 he took over some mills at Ashland, Wis., and a few years later also at Washburn, Wis., and Duluth, Minn., producing Norway pine. He became a specialist in this timber and made an enviable reputation for the splendid stock he cut. All timber was produced in his own camps and especially selected to suit requirements as to size, etc.

This practice is being followed by Mr. Gilbert in the southern white cedar business. He produces the timber in his own camps, has it specially selected for the service it is to render, and carefully inspected before shipment. As the result of this practice Mr. Gilbert has not had a single pole rejected this year. The accompanying illustration shows typical sections of southern white cedar, and also some characteristic boughs that Mr. Gilbert had prepared to show the excellent structure of this timber.



Several Typical Cross Sections of Southern White Cedar, Showing Good Structure for Pole Purposes.

Thordarson Apparatus for Amateur Radio Work.

To meet the needs of wireless experimenters who wish to make use of vacuum-tube equipment, the Thordarson Electric Manufacturing Co., 501-515 South Jefferson street, Chicago, has placed on the market special apparatus which is illustrated in the accompanying group cut.

Fig. 1 shows the new Thordarson wireless transformer, whose rating is 1 kilovolt-ampere and 25,000 volts. It is an air-cooled radio transformer of the closed-core, double magnetic circuit type. One of the magnetic circuits is variable to give wide regulation of voltage, capacity and reactance.

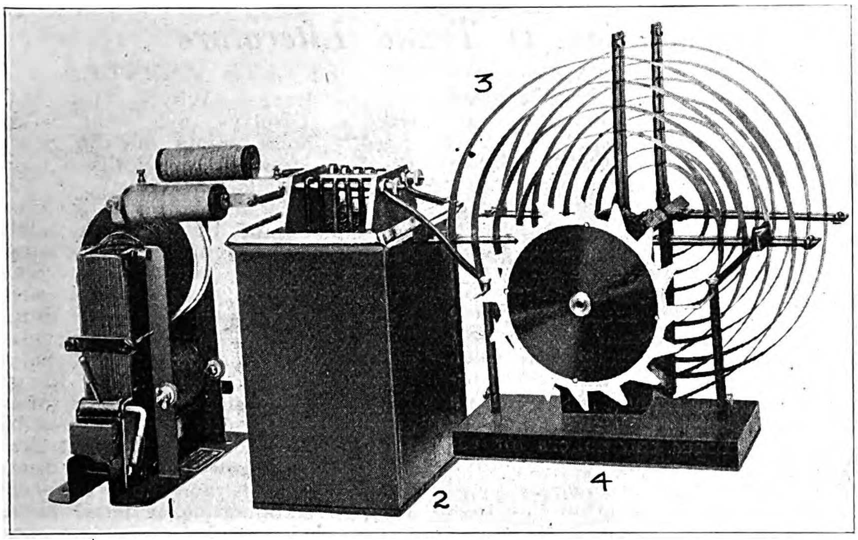
The core is made of high-grade silicon steel with laminations 8 mils thick.

The essential feature of this unit is its magnetic shunt and control which protects the transformer from undue current surges, such as are frequently present. These transformers can be connected directly to the alternating-current source without requiring a choke coil or other impedance. The construction of this transformer includes elimination of all castings, springs and adjustable screws, pressed sheet steel and brass clamps being used in place thereof. Regulation is accomplished by a simple system of levers and accentric cams, which are quiet in operation at all positions. A special mechanical and corona shield for the high-tension coils and a grounding terminal are provided. The coils receive a vacuum impregnating treatment and a special folded layer insulation is used for the high-tension coils. The transformer is entirely oil-proof and waterproof. It is very neatly assembled and makes an attractive unit in the radio set. Exceptionally high efficiency is claimed for this transformer.

In Fig. 2 is shown the special condenser for this equipment, the dielectric of which is phenol fiber, which has withstood potential tests at 48,000 volts before breaking down. It thus permits of an overload of nearly 100% when used with the Type R. 25,-000-volt transformer shown in Fig. 1. The edges of the sheet brass are rolled and the corners rounded, thereby preventing a loss of energy by corona or brush discharge. Between each two sheets of brass on each terminal of the condenser is inserted a third sheet which is corrugated. This arrangement permits the oil to penetrate and circulate, and at the same time prevents heating. There is practically no loss of energy due to heating, corona, or brush discharge, and therefore extremely high efficiency is attained. After assembling, the condenser is immersed in a container of oil, as it is a well-known fact that the greater number of long-distance amateurs use an oil-immersed condenser.

The outstanding feature of this condenser is the arrangement of the 10 terminals. The capacity can be increased from a minimum of 0.0018 mf. to a maximum of 0.009 mf. in single steps of 0.0009 mf. each. This permits very fine adjustment in the closed secondary circuit, and the number of turns on the primary of the oscillation transformer can be increased or decreased by merely decreasing or increasing the capacity of the condenser.

The oscillation transformer is shown in Fig. 3. The primary of this transformer consists of 3¾ turns of 1-in. heavy copper ribbon supported in fiber strips. The secondary consists of 7¾ turns mounted in the same way as the primary. The primary inductance is approximately 4.5 micro-henries. When the maximum turns on the primary are used with the condenser having a capacity of 0.009 mf., the wave meter shows a reading of 385 meters. Using one complete outside turn or an inductance of about 1.2 microhenries and a condenser capacity of 0.009 mf., the wave meter shows a reading of 205 meters. The secondary inductance is approximately 10.9 mi-



Figs. 1 to 4.—Thordarson Radio Transformer, Condenser, Oscillation Transformer and Rotor for Spark Gap.

crohenries. When using a condenser capacity of 0.004 mf. to 0.009 mf., a very select range of short wave lengths can be attained.

Fig. 4 shows a rotor for the rotary spark gap where the latter is to be used. The rotor of electrodes is of ⅛-in. hard aluminum, 8 in. in diameter. The center disk is phenol fiber. Actual test with the rotor of 16 teeth on a motor driven at 1000 r.p.m. to 1500 r.p.m. produces a low note with carrying quality. The same tone was produced with the rotor of 8 teeth and motor driven at 2000 r.p.m. to 3000 r.p.m. The tone can be varied by regulating the speed of the motor, but it is the low note that makes amateurs heard at long distance.

Dayton-Dowd Motor-Driven Single-Stage Centrifugal Pumps.

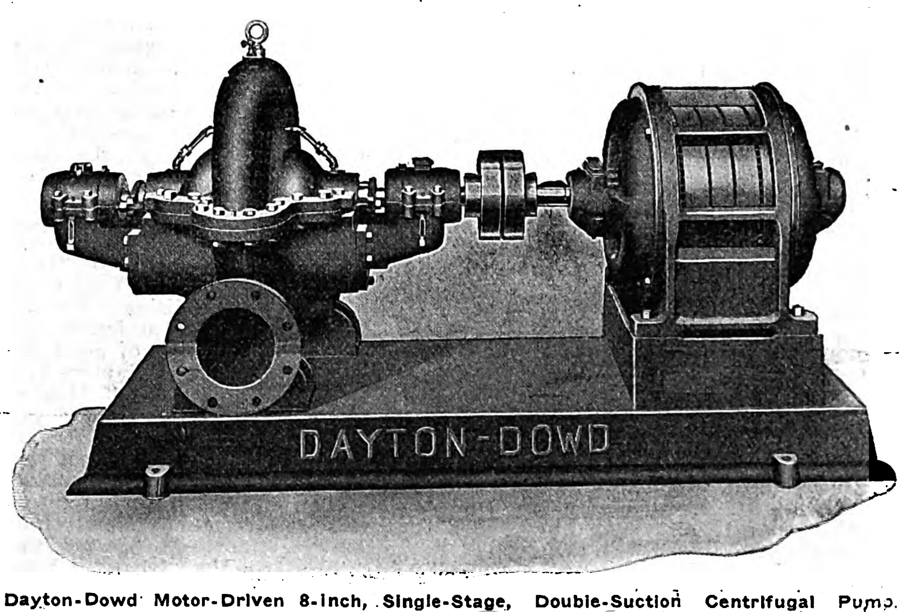
The simplicity of centrifugal pumps and their reliability in operation has won them so much favor that they are coming steadily into more and more extensive use, especially where motor or turbine drive is to be used. A large number of makes of centrifugal pumps are now on the market, and among these is a line that has been developed after many years of experience and has been employed in a great many installations, among the more notable ones being the Hog Island shipyards near Philadelphia, where six 8-in. pumps of this type are used; another case is in the water supply for the Great Lakes Naval Training Station which uses a 10-in. pump.

The pumps referred to are made by the Dayton-Dowd Co., Quincy, Ill. They are known as type CS single-stage double-suction volute centrifugal pumps and are made for either direct connection through an electric motor, steel turbine, oil or other engine, or for being driven by a belt. These pumps are built with special care for ruggedness and simplicity of construction and have excellent efficiency in operating characteristics. The main casing consists of two parts of which the upper half forms a cover and the lower half, with which are cast integral suction and discharge openings, and the feet. The upper half is provided with water seals, vents and an eyebolt for lifting; the lower half is provided with proper drains to permit draining the casing entirely when necessary. Between the two halves is the only joint in the casing; this is provided with a special manila paper gasket that sets between two specially machined surfaces, thus giving a perfectly water tight joint when the heavy flanges are securely bolted together. Although usually made of cast iron, under special conditions the case is furnished of bronze, brass or other material. Special bearings are provided outside of the pump casing so that any water leaking from the stuffing boxes will not enter the bearings or oil reservoir. All bearings are provided with oil rings to lubricate them thoroughly. Special care has been taken in the design and in the finish of the impeller. A special system is used for checking and polishing the interior of the impeller so that it coincides absolutely with the designs. In larger sizes a separate bronze wearing ring is shrunk in place on the impeller hub. There are also provided bronze case-wearing rings of wide section and machined to give a minimum running clearance with the impeller rings, so as to insure against leakage. The stuffing boxes are arranged for five or six rings of packing and a bronze water-seal ring. All of the pumps are provided with a flexible coupling of the pin and rubber bushing type, thus allowing a slight misalignment. In the case of belt-driven pumps an outboard bearing is provided, and in the larger sizes an additional bearing is provided beyond this to release the pump-bearing of the strain from a heavily loaded belt. These pumps are made in sizes from 1¼ in. up to 30 in. and with normal capacities of 30 to 26,000 gal. per min. Each size is made in various speeds and for various heads. Each pump is thoroughly tested to be sure it meets all of the conditions for which it is to be used.

Remarkable Success of Australian-Made Wireless Apparatus.

The wireless operator in the steamer *Karoola* has reported that when his ship was off the northwest coast of Australia he received clear messages from an English low power station in the North Sea which were transmitted on the ordinary short wave-length of 600 meters.

This feat was achieved with the new Expanse type magnifying valve receiver designed and manufactured in Sydney, Australia, by Amalgamated Wireless (Australasia) Limited. These receivers include a modified Fleming valve and were originally designed by the company's managing director, E. T. Fish, for demonstrating the possibility of receiving messages in Australia direct from the Marconi station at Carnarvon in Wales, nearly 12,000 miles away, or practically half way around the globe.



Dayton-Dowd Motor-Driven 8-Inch, Single-Stage, Double-Suction Centrifugal Pump.

Trade Activities

Large Power Plant for Pittsburgh — Successful Roller-Smith Conference — Distribution of Trade Literature

The C. H. E. Williams Co., electrical engineer and contractor, Seattle, Wash., and Vancouver, B. C., installed the electrical equipment in use in the new plant of the Kilbourne & Clark Manufacturing Co., in Seattle, which was described and illustrated in the ELECTRICAL REVIEW of July 19, 1919.

Dwight P. Robinson & Co., Inc., 61 Broadway, New York, has been awarded a contract by the Duquesne Lighting Co. of Pittsburgh, to design and construct a power station at Cheswick, near Pittsburgh, to have an ultimate capacity of 300,000 kw. of which one unit of 60,000 is to be installed initially. The work consists of a new power-station building with the necessary complement of boilers, piping, electrical apparatus, coal handling devices, coal storage, etc. It is anticipated that the work of installing the first unit will require about 12 months.

Wheeler Condenser and Engineering Co., Carteret, N. J., has issued a very clever and interesting little booklet entitled "What Worried Admiral Jellicoe Most." This little publication takes up extracts from Admiral Jellicoe's story of the grand fleet that deal with the big 11-in. guns and condenser tubes. The theme of the booklet is the importance of condenser tubes in a navy, the amount of anxiety caused the British admiral by condenser tube trouble, and the facilities at the disposal of the Wheeler Condenser and Engineering Co. for supplying condenser tubes and research. Tables of condenser tubes weights for tubes of copper and brass are included.

Roller-Smith Company, 233 Broadway, New York City, held a sales conference at its Bethlehem, Pa., works during the week of July 7. The following representatives attended this conference: G. L. Crosby, sales manager, New York; M. Frankel, assistant sales manager, Chicago; C. M. Hunt, New York; C. G. Kahant, export manager, New York; W. G. Merowit, Buffalo; C. H. Nicholson, Detroit; F. C. Perkins, Philadelphia; W. G. Pieksen, St. Louis; F. W. Ryan, Chicago; W. J. Shire, New York; J. E. Wood, Cleveland. In addition to the discussion of sales matters the social side of the conference was a source of much pleasure to all the Roller-Smith men. I. E. Hall, assistant works manager, and W. H. Pugh, superintendent, entertained the men at several functions during the conference. The conference ended in the Roller-Smith Company's New York office at 233 Broadway on July 10, subsequent to which the men who had attended returned to their respective offices. From every point of view the conference afforded much benefit as well as pleasure and the Roller-Smith Company is already making plans for a more elaborate conference at some later date.

Quigley Furnace Specialties Company, New York, has been awarded the contract for furnishing complete powdered-coal equipment for the new sheet mill of the Falcon Steel Company, now being erected at Niles, Ohio. The power-plant boilers will be powdered-coal fired, using the Quigley compressed-air system for transporting and burning the coal. The pulverized coal will be transported from the milling plant through standard 4-inch diameter wrought pipes to furnaces and boilers for various distances aggregating approximately 800 ft. and will be switched from the main distribution line to a storage bin in the power house for use as required for the boilers.

Karry-Lode Industrial Truck Co., Inc., Long Island City, New York, has now available for those interested specification sheets for their models No. 1 and No. 2 storage battery tractors and trucks. The Karry-Lode is an all-steel truck, strength with minimum weight is obtained by eliminating the heavy and unnecessary frame. The all-steel platform is the frame of the truck. In the model No. 2 one-point suspension prevents vibration and deflection of supporting members from affecting the motor and battery. In the specifications the details of capacity, weight, speed light and loaded, mileage per charge, motor, battery, tires, controller and safety devices are all given, together with a dimensioned drawing of the models.

Edison Electric Appliance Co., Inc., Hughes Division, Chicago, Ill., has available for distribution a 48-page book entitled "Hughes Electric Range Sales Service Manual." This book is a valuable treatise on the merchandising of electric ranges. From "The secret of successful electric range merchandising" the book gives a series of eight advertisements, each occupying a full page, in which the idea of cooking electrically is the all-important thing. The next nine pages are devoted to "How Form Letters Supplement Your Campaign in Merchandising Electric Ranges," in which form letters are discussed and a number of good letters are shown. Other chapters are: "The Purpose and Value of Hughes Pamphlets, Folders and Other Co-operative Literature," "Two Attractive Folders Intended for Special Distribution: They Cover Important Fields," "How to Use Movie Lantern Slides to Advantage in Merchandising Electric Ranges," "Street Car Advertising Is a Useful Part of Your Publicity on the Electric Way of Cooking," "The Window Display Is a Powerful Factor in Merchandising Electric Ranges—Why?" "Two Attractive Displays for Your Windows," "Some Hints on the Store Display—How Best to Utilize Your Space," "Details Covering Your Display of Hughes Electric Ranges, Floor Plans of Exhibit," "A Little About the Value of the Demonstration as an Aid to Increasing Interest," "Tying in Your Other Activities with Your Hughes Range Demonstration," "The Why and Wherefore of Demonstrations," "Salesmanship and Sales Methods," "After the Electric Range Is Sold and Installed." Repairs and service and co-operation furnished by Hughes salesman are then dicussed together with how the Hughes home economist helps and how to order Hughes co-operative material for a logical and complete campaign, and the expense. The booklet is profusely illustrated, the style is most attractive, the type clear and the paper good. This book should be of immense value to every central-station salesman, in fact to anyone concerned with salesmanship and the art of advertising.

Cutler-Hammer Manufacturing Co., Milwaukee, Wis., has prepared four envelope folders on the "C-H Seventy-Fifty" switch for use by dealers who wish to call their customers' attention to the fact that they are selling appliances equipped with this feed-through switch and also installing them on the cords of appliances purchased before this switch was available. Three of the books are standard envelope size (3½ by 6 in.), while the fourth is a miniature of one of the larger, being 1¾ by 3 in. All of the booklets are attractively printed in two colors. The miniature contains 12 pages, while the larger one like it, contains 8. Both are entitled, "Have You One of These?" and emphasize the advantage of buying electrical appliances with the cords equipped with these switches. They follow the national advertising in that they direct the public to the electric appliance dealer. The other two folders are four pages each. One is entitled, "C-H Seventy-Fifty Switch," while the other has for its title, "The Latest Models Have Them." The latter has a reproduction showing the damage resulting from pulling out the terminal connectors of electric irons, toasters, and other appliances and points out to the user that the C-H 70-50 switch is the remedy for these annoyances, since the necessity of removing the connector plug is eliminated, and in addition, safety from fire is provided because the white and black buttons of this switch indicate whether the current is "on" or "off." Large editions of these folders have been printed to supply the requirements of electrical dealers and lighting companies who use them in various ways among their customers and prospective customers.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Augusta, Me.—Cumberland County Power & Light Co. will extend its transmission lines from the end of its present line near Gray Corner along Poland Spring Road for two miles.

Boston. Mass.—Lighting Superintendent Mohr is advertising for bids for a contract to equip and maintain for one year 1300 mantle gas lamps and 218 mantle naptha lamps in locations where there are no gas mains or electric service.

Bridgeport, Conn. — Considerable electrical equipment will be required in connection with the construction of the proposed new isolation hospital by the City Board of Health, estimated to cost about $175,000.

Bridgeport, Conn.—Nichols Underwear Co., 395 James street, is making rapid progress on the construction of a new two-story plant and power house, about 76x195 ft., and 20x20 ft., respectively, to provide for increased capacity. The structures are estimated to cost $80,000.

New Britain, Conn.—Trumbull Electric Co. has completed arrangements for the erection of a four-story addition to its plant at Plainville, about 50x106 ft., to provide for increased operations. The company will also erect two one-story structures at the works, about 50x100 ft. and 56x100 ft., respectively. Contract has been awarded to Louis A. Miller, 68 Wilcox street, Meriden.

Brunswick, Ga.—The City Suburban Railway Co. will extend its line. Address general manager.

Elberton, Ga.—Aug. 27 an election will be held to decide the question of issuing $15,000 electric light bonds. Address W. A. Nall, mayor.

Cranston, R. I.—United Wire & Supply Co. has awarded a contract to William H. Hamlyn & Son, 35 Greenwich street, Providence, for the erection of a two-story addition to its plant in the Auburn district, about 40x250 ft. The structure is estimated to cost about $100,000.

Woonsocket, R. I.—Plans have been filed by the French Worsted Co., Hamlet avenue, for the erection of an addition to the boiler plant at its works, about 40x50 ft. Contract for the structure, which is estimated to cost about $35,000, has been awarded to Wilfred Aubin, 1103 Dimond Hill road.

Binghamton, N. Y.—In connection with the expansion program of the Endicott-Johnson Corp., including the erection of a large addition to double the present capacity of the plant, considerable additional power will be required for operation. Electric energy is furnished by the Binghamton Light, Heat & Power Co.

Brooklyn, N. Y.—Brooklyn Rapid Transit Co., 85 Clinton street, is understood to be considering plans for the erection of a large brick and stone power station at Kent avenue and South Sixth street, to provide for increased operations.

Falconer, N. Y.—Merriam Cabinet Co. plans to remodel the Chautauqua Planing Mills and install electric power units. Total estimated cost, $60,000.

New York, N. Y.—Announcement has been made of the suspension of operations of three New York traction companies, due to inadequate operating revenue. The concerns affected are the Mid-Crosstown Railway Co., operating on 28th and 29th streets; Edward A. Maher, president; the Pelham Park & City Island Railroad Co., and the Third Avenue Bridge Co. Notice has been filed with the Public Service Commission of intention to cease operations, holding that they were operating at a loss.

New York, N. Y.—Bruston Automatic Electric Lighting & Power Co., 101 Park avenue, has filed an involuntary petition in bankruptcy, showing liabilities of $60,000 and assets of about $10,000. Judge A. N. Hand has appointed Roger B. Wood receiver of the company; John P. Hopson is president, and George Wishart, treasurer.

New York, N. Y.—New York Telephone Co., 15 Dey street, has awarded a contract for the erection of a two-story addition to its telephone building at West New Brighton, Staten Island, to provide for increased capacity. Extensive alterations and improvements will also be made in the existing structure. John O'Devlin, 233 Broadway, New York, is the building contractor.

New York, N. Y.—Roechling Electric Steel Co., 173 Lafayette street, has filed notice with the Secretary of State of the dissolution of the corporation.

New York, N. Y.—Rapid progress is being made in connection with the construction of the proposed Fourteenth Street-Eastern District subway, which will extend from Sixth avenue, New York, through Fourteenth street, to a connection with the Brooklyn Rapid Transit elevated system near East New York. Contract for the work was awarded to Booth & Flinn, Ltd., at a cost of about $6,639,000, and it is expected that to complete the work will require about 10 months' time.

New York, N. Y.—Sibley-Pitman Electric Corp., 190 Sixth avenue, manufacturer of electrical specialties, has filed notice with the Secretary of State of an increase in its capital from $150,000 to $250,000, to provide for general business expansion.

Oswego, N. Y.—City intends to construct and equip a complete electric lighting system at cost of $90,000. Major Bensel, consulting engineer.

Cape May, N. J.—Board of Public Utility Commissioners has approved the sale of the Vulcan Electric Light, Heat & Power Co. to the Cape May Court House Light & Water Co. for a consideration of $35,072, and for certain proposed bond issues by the petitioner. It was held that the Vulcan company was in default on the payment of interest on outstanding bonds, aggregating $32,000.

Garwood, N. J.—The plant of the C. & C. Electric & Manufacturing Co., Center street, manufacturer of electrical specialties, etc., has been offered for sale by William Tuttle, Jr., receiver. The works are located on the main line of the Central Railroad of New Jersey on property comprising about five acres, the various structures having a total of 60,000 sq. ft. of floor space, and are fully equipped for all departments of operation.

Lakewood, N. J. — Lakewood & Coast Electric Co. has been granted permission by the Board of Public Utility Commissioners to place into effect a new schedule of rates to yield additional revenue needed to meet the increased cost of operation.

Newark, N. J.—Announcement has been made that satisfactory agreements have been entered into between the striking tool makers and machinist specialists and officials of the Splitdorf Electric Co., 98 Warren street. The strike involved about 300 persons, and it is understood that various demands of the strikers have been granted.

Newark, N. J.—Public Service Corp. has been authorized by the Board of Public Utility Commissioners to place into operation, effective Sept. 14, a new zone plan for the collection of fares. It is proposed to charge three cents for travel within the first zone mile, with a charge of two cents for each additional zone mile or part thereof. The new rates will replace the flat seven-cent fare now in force on the company's system.

Perth Amboy, N. J.—Board of Aldermen is considering plans for the purchase of the plant of the Perth Amboy Gas Light Co., to be used for municipal service. It is understood that estimates of valuation of the property are now being taken, and it is expected that this work will be completed around the end of September.

South Amboy, N. J.—City Council is understood to be arranging plans for extensions in the electric street-lighting system, and the installation of new lighting units of increased capacity. Electric service is furnished by the Monmouth Lighting Co.

Trenton, N. J.—Plans are under consideration by the City Commission for improvements in the municipal lighting system.

Allentown, Pa.—Allentown-Bethlehem Gas Co. has filed a new tariff of rates for its Allentown district, Bethlehem, Catasauqua, and Hellertown districts, effective Sept. 1. The schedule covers a minimum monthly charge of 25 cents per meter of 3 or 5 lights; 5, 10, 20 or 30-light meters, 50 cents per meter per month; 45, 60, or 80-light meters, 75 cents per meter per month; and 100-light capacity meters and over, $1 per month, all the above being service charges.

Allentown, Pa.—Board of Managers of Allentown hospital has recently completed alterations and improvements in the boiler plant at the institution, to facilitate operations.

Allentown, Pa.—S. & W. Electrical Co. has recently inaugurated operations in its new establishment at 613 Turner street. It is proposed to engage in general electrical repair and construction. William S. Solliday, formerly connected with the Lehigh Electric Co., and Edgar Weaver, also associated with the same company, are partners in the new organization.

Catasauqua, Pa.—Work has recently been completed by the Borough Council on the installation of new lighting units of increased capacity for the municipal street-lighting system. About 400 units were installed.

Harrisburg, Pa.—It is interesting to note the number of increases recently filed with the Public Service Commission, covering the issuance of stock or bonds. Among the companies notifying the Commission are: Renovo Edison Light, Heat & Power Co., Renovo, common stock, $18,500; Eastern Pennsylvania Railways Co., Pottsville, bonds, $198,000; Allentown-Bethlehem Gas Co., Allentown, bonds, $210,000; Philadelphia Rapid Transit Co., Philadelphia, equipment trust certificates, $88,000, and bonds, $174,000.

McMurray, Pa.—McMurray Telephone Co., operating in Washington county, has filed a new schedule of rates for service, effective Sept. 1. It is proposed to increase the existing rates 20%, with an extra charge for extension and installation.

Mauch Chunk, Pa.—Mauch Chunk & Lehighton Transit Co. has filed notice of the issuance of preferred stock for $50,000, common stock for $150,000, and bonds for $130,000, to provide for proposed business expansion.

Nanticoke, Pa.—Dunlap Silk Co., Hazleton, is having plans prepared for the construction of a new brick and concrete boiler plant at its local silk mills. The structure will be two stories in height, about 90x100 ft. Emil Buehler is local manager.

Philadelphia, Pa. — Announcement has been made by the Philadelphia Rapid Transit Co. of an increase in the wages of its conductors and motormen of seven cents per hour. The increase will affect about 6000 persons.

DATES AHEAD.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug 26-28. Headquarters, Hotel Ottawa. Secretary-treasurer, Herbert Silvester, Monroe, Mich.

Pennsylvania Electric Association. Annual convention, Bedford Springs, Pa., Sept. 3-6. Secretary, H. M. Stine, 211 Locust street, Harrisburg.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston Block, Seattle.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

American Electrochemical Society. Fall meeting, Chicago, Sept. 23-26. Headquarters, Congress Hotel. Secretary, Prof. Joseph W. Richards, Lehigh University, Bethlehem, Pa.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Headquarters, Auditorium Hotel. Secretary, Clarence R. George, Houston, Tex.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Philadelphia, Pa. — Contract has been awarded to Ketcham & McQuade, Philadelphia, for the construction of a boiler plant at the Globe Theatre, 59th and Market streets, to facilitate operations.

Philadelphia, Pa.—County Gas & Electric Co. has filed notice with the Public Service Commission of a bond issue for $1,800,000, to provide for general business expansion.

Philadelphia, Pa.—Plans are being prepared by the Department of Public Works for the construction of a one-story brick, stone and steel pumping station at the municipal waterworks plant at Lardners Point, to provide for increased capacity. It is understood that the station will be electrically-operated.

Pittsburgh, Pa.—Equitable Gas Co., the Allegheny Heating Co., and the Monongahela Natural Gas Co. are co-operating in a campaign for the economical use of gas throughout the local territory served, including both retail and wholesale consumers. The companies urge the installation of modern methods for gas burning and other features of operation to bring about greatest efficiency.

Pittsburgh, Pa.—Notice has been filed with the Public Service Commission by the Beaver County Light Co. for the issuance of bonds for $24,000, to provide for general business expansion.

Pittsburgh, Pa.—Westinghouse Electric & Manufacturing Co. has recently commenced the construction of a large building in Braddock avenue, East Pittsburgh, to be used as a restaurant for employes. The new structure will be three stories in height, and will be connected with the works by an overhead bridge. It is estimated to cost about $250,000.

Sayre, Pa.—Sayre Electric Co. has recently been awarded a contract for furnishing additional electric power for the operation of the Sayre Brass Foundry, managed by the Cayuta Mfg. Co. A total of 100 hp. is required.

Titusville, Pa.—Titusville Light & Power Co. has recently placed into effect increased rates for service.

Baltimore, Md.—Board of Awards has awarded a contract to George R. Bullen, Baltimore, for the installation of a modern heating plant at Public School No. 63, Gough and Wolfe streets.

Wheeling, W. Va.—Fire, Aug. 5, damaged the engine plant at the local branch of Wilson & Co., with total loss estimated at $10,000. It is understood that immediate repairs will be made.

Gaffney, S. C.—City will establish white way lighting system. Superintendent of Light and Water plants.

Belleview, Fla.—Belleview Utilities Co., recently organized, is arranging for the construction of a local plant, estimated to cost $10,000. It is proposed also to construct a transmission system covering seven miles for initial operations. The company recently filed articles of incorporation with a capital of $25,000. James Conway, Harvard, Ill., is engineer.

Miami, Fla.—Miami Electric Light & Power Co. is planning for the reconstruction of its local power plant, with extensive alterations and improvements, to facilitate operations. It is understood that the work is estimated to cost in excess of $150,000.

Sarasota, Fla.—City has completed arrangements for the construction of a power plant for municipal service. The structure is estimated to cost, with machinery installation, about $42,000. The Southern Construction Co., St. Petersburg, is the contractor.

NORTH CENTRAL STATES.

Cleveland, O.—Drew Electric Mfg. Co. contemplates erecting a plant, 2 stories, 80x204 ft., to cost $35,000. D. W. Morrow, Garfield building, is architect.

Hamilton, O.—The council has appropriated $15,000 additional for extension of electric plant. The director of public service was authorized to contract for the labor and material necessary for the extension of the transmission lines.

Marion, O.—The C. D. & M. Electric Co. will install 7 additional lights.

Toledo, O.—Swartz Electric Co. is preparing plans for a factory addition that will practically double the floor space.

Anderson, Ind.—Earl P. Creager, works manager of the plant of the Remy electric division of the General

Motors Corp. here, has announced that the laboratories and sales department of the Remy plant, which have been at Detroit for about five years, will be returned to Anderson within a few days. The laboratories will be in the five-story building that has just been completed at the Remy plant and which also includes the general offices of the company. The additional employes will make a total of about 3800 at the Remy plant. With these departments will come the skilled employes connected with the laboratories and sales department, including C. E. Wilson, who recently was made manager of the sales department, and Dr. M. W. Franklin, in charge of the research department.

Auburn, Ind.—A plan is under way here to organize a stock company with capital of $100,000 for the purpose of erecting 35 or 40 houses, costing from $2000 to $2500 each. Address W. H. Schaab, president, Auburn Commercial Club.

Connersville, Ind.—Ansted Engineering Co. will erect factory building 100 ft. wide and 400 ft. long. The Lexington Motor Co., to which the Ansted Engineering Co. is largely accessory, will build a stockroom and expand its heating system. Work on the foundation of the engineering company's building has just been begun. Work on the other buildings will begin about Sept. 1.

Connersville, Ind. — The Teetor-Hartley Motor Corp., owned principally by Connersville capital, but now situated in Hagerstown, Ind., has purchased ten acres near its Connersville factory area, and will begin the erection of a steel and concrete building 100 ft. wide and 1500 ft. long.

Fort Wayne, Ind.—Officials of the Fort Wayne branch of the General Electric Co. say that the constant increase in business has made the demand for help large and that the company is daily adding to the already large number of employes. With a very few exceptions every line of work carried on by the General Electric Co. is demanding more laborers, both skilled and unskilled. In case there is any slack in any department the men are transferred to departments needing them. R. F. Smith, in charge of the electrical testing and drafting courses, states that the company is still receiving applications for these courses, which are three years long.

Indianapolis, Ind.—The J. G. White Engineering Co., a Connecticut corporation, has withdrawn from business in Indiana.

Mishawaka, Ind.—Grange Elevator Co. will erect $30,000 warehouse. The company has recently been organized with capital of $50,000. M. H. Huston is the president.

Paoli, Ind—The Johnson Ice Cream Co., Bloomington, Ind., will erect $30,000 plant here.

Roachdale, Ind.—Roachdale Electric Co. has increased its capital stock from $50,000 to $100,000.

South Bend, Ind.—The Northern Indiana Gas & Electric Co. has been authorized by the Indiana Public Service Commission to issue $1,067,000 of 10-year notes for the purpose of improving its properties, these improvements to be made in South Bend, Fort Wayne, Lafayette, Logansport, Michigan City, Hammond and Peru.

Warsaw, Ind.—Winona Assembly management plans erection of a $100,000 auditorium.

Elgin, Ill.—Owing to a strike on the lines of the Aurora, Elgin & Chicago Railroad Co., which has tied up the entire light and power service in Elgin and adjacent towns, the management of the Sherman hospital has decided to install a generator. Mrs. Mary S. Pease has been named chairman of a committee to purchase the generator and equipment.

Freeport, Ill. — Electric lighting rates of the Northern Illinois Utilities Co., affecting this city and Dixon, have been increased by the Illinois Public Utilities Commission, one-half of the war emergency being allowed. The new rates add one and one-half cents to the rates in effect a year ago when war conditions made an increase imperative. Marengo, Harvard and Hampshire are also among the towns served by the company.

Medora, Ill.—An election will be held to decide the question of issuing $12,000 light and power bonds. Address city clerk.

Oswego, Ill.—Consulting Engineer John A. Buesel will prepare specifications for lighting plant equipment to cost $70,000.

Springfield, Ill.—Illinois is taking the lead in a movement to have its county highways lined with electric lights. A plan to have lights strung all the way along the Lincoln Trail, which bisects the state from Terre Haute, Ind., to East St. Louis, and on down to Cairo, is to be lighted if the plans of the promoters are carried out. It is planned to extend lights each way from cities which have plants and it is estimated that farmers will use enough current to pay the expenses. Lighted country highways will offer a novelty to motoring tourists. Illinois is spending $60,000,000 on permanent roads and the proposition to light them is gaining strength.

Lansing, Mich.—Voters have approved issuance of bonds for public improvements amounting to $1,321,000. Bond issues approved are: Municipal light and water plants, $650,000; isolation hospital, $100,000; addition to cemetery, $38,000.

Three Rivers, Mich.—Eddy Paper Co. will erect an electric power plant in connection with the construction of a 1-story paper mill. The entire project is estimated to cost in excess of $1,000,000.

St. James, Minn.—An issue of $20,000 lighting plant improvement bonds authorized by City Council.

Atkins, Ia.—The town of Atkins has decided to have a system of electric lights. At present it has not been decided whether a system be put in at Atkins or whether connections would be made with the line of Iowa Railway & Light Co.

Story City, Ia.—David G. Feshut Co. awarded contract for electric light system and power house at $36,000.

Coats, Kans.—A petition is being circulated asking the mayor and councilmen of the city to call an election to vote bonds for an electric light plant and system.

Ellsworth, Kans.—The installation of a white way is being seriously contemplated.

Ft. Scott, Kans.—All of the properties of the Ft. Scott Gas & Electric Co., including the electric plant, the gas plant, the defunct street railway, was sold at sheriff's sale July 31 to satisfy a first mortgage of $35,000, etc.

Hanover, Kans.—Engineers Black & Veatch, 507 Inter-State building, Kansas City, Mo., have prepared plans for improving electric system.

Hanover, Kans.—A power dam is to be built on Little Blue river here, to cost $150,000. A flour mill will probably be built and the city electric light and waterworks will also use the power besides furnishing power to outside towns.

Harper, Kans.—Plans are being made for a White Way in the business part of the city.

Hazelton, Kans.—Election to vote bonds for an electric lighting system carried.

Hudson, Kans. — City is having plans prepared by W. B. Rollins & Co., engineers, 209 Railway Exchange building, Kansas City, Mo., for the construction of a transmission line for electric plant. Estimated cost, $15,000.

Manhattan, Kans.—The Kaw Valley Transmission Co., of St. George, the Riverside Light & Power Co., of Abilene, the Central Kansas Power Co., of Abilene, the Marshall County Power & Light Co., and the Rocky Ford Milling & Power Co., will soon be reorganized into one company known as The United Light & Power Co.

Manhattan, Kans. — Rocky Ford Milling & Power Co. is having plans prepared for a 2-story building and will install a 7000-hp. steam engine and 3000-kw. and 2000-kw. turbines. Total estimated cost, $500,000.

Pittsburg, Kans. — Appropriation has been made by the Bell Telephone Co., at Pittsburgh, for rebuilding and remodeling the plant and installing new equipment. Work will begin in November.

Scranton, Kans.—Election will be held in the near future to vote $4000 in bonds to provide funds for the extension of the electric light system.

SOUTH CENTRAL STATES.

Hazard, Ky.—Kentucky & West Virginia Power Co. will enlarge plant by taking over three large electric power plants.

Centreville, Tenn.—$15,000 electric light bonds have been voted. Address mayor.

Chattanooga, Tenn. — Cumberland Telephone & Telegraph Co. has recently made announcement that following the return of the telephone properties by the Government to their corporate ownership, plans have been perfected for extensive improvements and additions to increase the present capacity. Extensions will be made in existing transmission systems, and other enlarged facilities will be provided for, the entire work being estimated to cost in excess of $2,000,000.

Beggs, Okla.—Beggs Power & Ice Co. is understood to be considering plans for the construction of a local electric-light plant. The structure will cost about $75,000.

Comanche, Okla.—Town Council having plans prepared for alterations and improvements in the municipal electric light plant, estimated to cost about $10,000. A. L. White is town clerk.

Eufaula, Okla.—$25,000 bond issue for electric lights and waterworks carried recently. Bids will be advertised soon.

Frederick, Okla. — The city has voted $40,000 electric light bonds. Address mayor.

Oklahoma City, Okla.—The Attorney General has approved a bond issue of $110,000 for electric lights in Newkirk.

Oklahoma City, Okla.—Oklahoma Gas & Electric Co. will take a long term lease on a three-story and basement building, 50 by 140 feet, to be erected on First street, just east of Broadway. The offices now occupied by the company have grown inadequate.

Oklahoma City, Okla.—Election to vote $350,000 in bonds for water main extension was defeated.

Oklahoma City, Okla.—Oklahoma Gas & Electric Co. will erect at once an electric sub-station at 23rd and Ollie avenue. The station will be connected with a high voltage line and will serve northwest residence section.

Perry, Okla.—A bond issue of $260,000 is being contemplated for the purpose of entirely rebuilding and equipping the electric light and water system, also for the construction of a dam. Water mains will be extended and a White Way is considered.

Perry, Okla.—$260,000 in bonds have been voted for rebuilding and enlarging electric light plant and water system.

Perry, Okla.—Plans are under consideration by the city for the issuance of bonds for $260,000 to cover the cost of enlarging and rebuilding the municipal electric-light plant, water and wire systems, etc.

Tishomingo, Okla.—Bids will be advertised about Sept. 1 for electric plant, distribution system and ice plant. F. L. Yarger, city clerk. Johnson & Benham, Firestone building, Kansas City, Mo., engineers.

Tonkawa, Okla.—Preliminary plans are in progress for the extension of the waterworks system and electric plant to cost $117,000. Election to vote the bond issue will be held in the near future. R. R. Redfield, city clerk.

New Orleans, La.—Bids will be received Aug. 30 for furnishing and installing mechanical and electrical equipment including fuel oil pumps, a sludge pump, a deep well pump, fuel oil heaters, a steel flue, superheaters, soot-blowers, plumbing and plumbing fixtures, piping, switchboard, motor-driven exciter, transformers, electric fixtures, wiring and an electric traveling crane and for installing a turbine driven exciter, one 300 and one 320-hp. boilers, two feed-water heaters, and a V notch meter in the power plant at the Naval Station. Address C. W. Parks, Chief of Bureau.

Independence, Mo.—A recommendation that $50,000 bonds be issued for the purpose of building an addition to the power house of the electric plant and for installing a new unit current for the production of current was made to the city council. Address mayor, Christian Ott.

Palmyra, Mo.—Election to vote $10,000 in bonds for the improvement of the present electric light and water plant carried. H. M. Howard, city clerk.

St. Joseph, Mo.—Plans have been completed by the St. Joseph Railway, Light, Heat & Power Co. for extensive improvements and alterations in its plant, to provide for increased capacity. The work includes the installation of a quantity of new equipment, to comprise 12,500 kw. turbine, equipped with surface condensers and auxiliary switchboard equipment, boiler feed pumps and other apparatus, and is estimated to cost in the neighborhood of $1,000,000.

St. Louis, Mo.—St. Louis Mfg. Co. has recently completed plans and awarded a contract to the A. H. Haeseler Building & Construction Co., Wainwright building, for the erection of a power plant for factory operation, about 95x150 ft. The structure is estimated to cost, with equipment installation, $125,000.

Austin, Tex.—The Southwestern Telegraph & Telephone Co. recently purchased a site for a telephone exchange building.

Breckenridge, Tex.—J. E. Lewis, of Dallas, has purchased the local light plant and is making plans for a reconstruction of the old plant and the installation of new machinery. The new company has been granted a 50-year franchise by the city council.

Bryan, Tex.—Election will be held Aug. 26th to vote $75,000 in bonds for the purchase and improvement of the Bryan power plant.

Bryan, Tex.—The Bryan & Central Texas Interurban Railway Co. will transform its motive power from electric to steam equipment. The line runs from Bryan down the valley of the Brazos river 22 miles.

Cisco, Tex. — The Southwestern Telegraph & Telephone Co. has completed a survey of the city for installation of a standard common battery telephone system.

Dallas, Tex.—Notice has been filed with the Secretary of State by the Dallas Power & Light Co. of an increase in its capitalization from $1,000,000 to $2,500,000, to provide for general business expansion.

Dallas, Tex.—S. B. Brooks, of Greenville, has purchased at sheriff's sale the physical holdings and franchise of the Eastern Texas Traction Co. Construction of this interurban electric railway, to run between Dallas and Greenville, about 50 miles, was in progress at the time the great war caused a suspension of the work in 1914. It is planned by Mr. Brooks to reorganize the company and complete the line.

Dallas, Tex.—The Dallas Power & Light Co. has increased its capital from $1,000,000 to $2,500,000.

Dallas, Tex.—The Texas Power & Light Co. of Dallas will build a power transmission line from Dublin to De Leon and Gorman. The company plans also to extend its power lines to other parts of Central West Texas where extensive oil development operations are in progress.

Fort Worth, Tex.—It is stated by H. E. Robinson of Fort Worth, president of the Fort Worth & Western Electric Railway Co., that two routes for the proposed interurban railway, between Fort Worth and Mineral Wells, are under consideration, and as soon as it is decided which will be used the construction will be started. Part of the construction material has been ordered. The line will be about 65 miles long.

Hearne, Tex.—The capacity of the Hearne city light and water plant is to be increased 100%.

Houston, Tex.—According to Ed Kenedy, of Houston, promoter of the Houston, Richmond & Western Traction Co., the construction of the company's proposed interurban electric railway, that is to run between Houston and San Antonio, with a branch from Yoakum to Victoria, will be started as soon as materials can be shipped. The main line will be about 225 miles long and the branch about 30 miles.

Houston, Tex.—Nearly $500,000 will be spent by the Houston Light & Power Co. in extending its lines down the north side of the ship channel. A greater part of the money will be spent for dynamos and other machinery.

Luling, Tex.—The question of issuing $75,000 water and light bonds will be submitted to vote. Address mayor.

Orange, Tex.—The Orange Ice, Light & Water Co. has increased its capital from $60,000 to $100,000.

San Angelo, Tex.—City has decided to build its own water, light and power plant; $500,000 has been appropriated.

Sugarland, Tex.—The Sugarland industries will install an electric power plant.

WESTERN STATES.

Libby, Mont.—The Lukens-Hazel Mining Co. will expend $240,000 for a 200-ton concentrator and power plant. A pipe line will be installed from Granite Creek which will develop 600 hp.

Grand Junction, Colo.—Movement has been started at Collbran for installation of hydroelectric plant to supply power and light to practically every section of Plateau Valley.

Boise, Ida.—Mackay Light & Power Co. has been granted permission by the Public Utilities Commission to extend its transmission lines through the Lost Valley section to Arco, to provide increased operating facilities.

Personal

Charles McKay Joins L. V. Estes, Inc.—E. N. Lake Organizes — W. S. Wyche Returns to Arkansas Valley Co.

J. Frank Harper, of Centerville, Md., has been appointed a member of the Maryland Public Service Commission to succeed Albert Towers, recently resigned.

J. F. Owens, vice-president and general manager of the Oklahoma Gas & Electric Co., was recently elected second vice-president of the Oklahoma City Chamber of Commerce.

O. A. Rofelty, manager of the Sioux Falls, (S. D.) Division, of the Northern States Power Co., was recently elected president of the South Dakota Electric Power Association.

Herman G. Hardy, formerly connected with the Old Hickory Powder Plant at Jacksonville, Tenn., is now chief mechanical and electrical engineer of the Arizona Copper Co., Ltd., Clifton, Ariz.

N. S. Braden, former sales manager, has just recently been elected vice-president of the Canadian Westinghouse Co., Ltd., of Hamilton, Ontario. H. M. Bostwick, assistant sales manager, has been appointed sales manager, to fill the vacancy created by Mr. Braden's promotion.

Edward N. Lake, formerly manager and treasurer of the Krehbiel Co., and previously resident engineer of Stone & Webster, has organized the Lake Engineering Co., of which he has become president. The company will engage in general engineering work and will be located at 139 N. Clark street, Chicago.

E. T. Sawyer has recently accepted a position as a representative of the railway sales department of the U. S. Light & Heat Corp., Niagara Falls, N. Y. Mr. Sawyer will specialize on car lighting equipment and electric arc welders and will make his headquarters at 30 East Forty-second street, New York.

Lawrence B. Chapman, of the technical staff of the Electric Boat Co., New London, Conn., has been appointed associate professor in the new course of ship construction and marine transportation instituted last year at Lehigh University. Professor Chapman is a graduate of the Massachusetts Institute of Technology.

Joseph Harris, for 30 years a dominant figure in automatic telephony and president of the Automatic Telephone Co. of Chicago, Ill., has resigned from this position to become chairman of its Board of Directors. He will be succeeded by A. F. Adams as president of the company.

Several other changes have also been made in the organization of this company. H. L. Gary has been elected vice-president and treasurer; H. A. Harris, vice president and general manager, and W. F. Benoist succeeds H. A. Harris as its sales manager.

Charles W. McKay, formerly connected with the engineering firm of McMeen & Miller, Chicago, and subsequently with the Cooley & Marvin Co., of Boston, has recently taken charge of the Appraisal Division of L. V. Estes Incorporated of Chicago. Mr. McKay is the author of the series of articles now running in the Electrical Review on the general subject of Electric Utility Rates and Valuations. Mr. McKay's removal to Chicago will be of especial interest to the readers of the Electrical Review in that it places him in closer touch with the electric utility field and will enable him to give more attention to the features of the series

Charles W. McKay.

which involve the answering of questions. Mr. McKay has been engaged in engineering and appraisal work since his graduation from Sibley College of Mechanical Engineering, Cornell University, in 1906. In July, 1906, he entered the employ of the New York & New Jersey Telephone Co. (now the New York Telephone Co.), and after serving a brief apprenticeship in the maintenance department was assigned to the plant-engineering department. In 1909 he was appointed engineer for the North Brooklyn district, having charge of the preparation of plans and estimates for all outside construction work within the district. In 1910, at the time the New York Telephone Co. absorbed all of the up-state Bell companies, Mr. McKay was assigned to special work and spent the greater part of the following year in inspecting a number of the larger of the company's newly-acquired properties, and in 1911 was appointed engineer for the Borough of Queens. During the year 1912-13, Mr. McKay was associated with Henry Floy in the capacity of assistant engineer, and while holding this position he was identified with several important appraisal cases. In the summer of 1913 he became engineer to the McCall & Clark Co., efficiency experts of New York, and in October, 1913, became affiliated with McMeen & Miller, of Chicago. While with this well known enginering firm, Mr. McKay spent the major portion of his time on problems involving the appraisement of public utility properties. He later engaged in valuation work for the Central Union Telephone Co., and continued in this capacity until his appointment with the Cooley & Marvin Co. He is a prolific writer on appraisal subjects and has contributed extensively to the technical press. The Appraisal Division of L. V. Estes Incorporated, of which Mr. McKay will have full charge, will specialize in problems involving the appraisement of electric utility and industrial properties. L. V. Estes Incorporated are known to many of the readers of the Electrical Review through their extensive work for the electric industries.

Karl G. Roebling, president of the John A. Roebling's Sons Co., Trenton, N. J., has been elected a director of the American Ship & Commerce Corp., New York City.

W. L. McCloy, Jr., Pittsburgh, has been appointed general manager of the Philadelphia Co., Pittsburgh, to succeed Caroll Miller, resigned. Mr. McCloy has been connected with the Philadelphia Co. for more than 30 years, having risen to the position of general superintendent before the final promotion to general manager.

Capt. W. S. Wyche of the Second Engineers, U. S. A., has returned from overseas and rejoined the Arkansas Valley Railway Light & Power Co., Victor, Colo. Captain Wyche was twice honored for bravery in action. Once he was decorated with the Croix de Guerre with palm conferred by Marshal Petain, and once he received a special enlarged citation from General Pershing.

Col. H. M. Byllesby is serving on the Special Technical Jury appointed to investigate and report on the cause of the recent dirigible balloon disaster of Chicago. Colonel Byllesby is also treasurer of the Illinois State Committee for the National Celebration of Constitution Day Sept. 17. This movement is in connection with efforts which are being made to counteract Bolshevism and other non-American influences.

Obituary.

Emil H. Schmidt, Rochester, N. Y., superintendent of the municipal Police Telegraph & Fire Bureau, died suddenly on August 6, following an attack of heart failure, at his home, 189 Canterbury road. Mr. Schmidt was in his fiftieth year.

Financial News

Business Conditions.

Judging by current trade and the demand for money and labor the country is in a most prosperous state. The situation is remarkable for mid-summer, when some slackening of activity, and of pressure for goods and money is usual. It is extraordinary when we recall the uncertainty as to prices and trade prospects which existed a few months ago, but illustrates how great a factor is confidence. The change is due to a re-establishment of confidence so far as the immediate future is concerned. Everybody is satisfied that a great trade is ahead for the remainder of this year, and they are now busy preparing for that. Beyond that the situation is not so clear, but the people who must buy goods now for next spring are generally feeling that they must go ahead upon the present basis and get ready for it, taking the chances. They realize that sooner or later they will be caught by a declining market, but unless they want to go out of business they must be ready to do business, making the best of vicissitudes.

At present there is a cry from all parts of the country for goods. Prices on goods ready for delivery are a secondary consideration. Practically full employment and high wages in the industrial centers is an obvious factor but underlying that is the confidence and prosperity which pervades the agricultural districts, and back of it all are the enormous purchases which other countries are making here, as shown by the astounding figures for exports. It is well to know the source to which we are indebted for this trade, because it is not a source that can be relied upon to play so large a part permanently, and there is much in the home situation that is disquieting.

U. S. Rubber Company to Increase Capital.

At a meeting of the Board of Directors of the United States Rubber Co. held in New York City on Aug. 7, an increase in capitalization was unanimously authorized. The action of the board was taken in compliance with the recommendation of Samuel P. Colt, chairman of the board, as a means of providing the capital necessary to finance the increasing volume of business that is in evidence. The directors announced their intention of placing the common stock on an 8% dividend basis, beginning next October, and stated that, if earnings warrant the action, a substantial extra dividend will be paid to stockholders in the spring of 1920.

Stockholders of record on Aug. 8 will meet on Sept. 7 to vote on the proposal for the increase of stock. If the stock issue is authorized, shares of the new common will be offered to present stockholders for subscription at par, or $100 per share, on the basis of one new share for one old share now held. After recommending the increase to provide a total capitalization of $100,000,000 preferred and $200,000,000 stock on the retirement of the present second preferred, the chairman said:

"The volume of business transacted by the company for five years in round numbers was $83,000,000 in 1914, $92,000,000 in 1915, $125,000,000 in 1916, $176,000,000 in 1917 and $215,000,000 in 1918. During that period the capital stock of the company remained substantially the same.

"The indebtedness of the company was funded in 1917 into long term 5% bonds. The surplus earnings for the years 1917 and 1918 were equivalent each year to about 30% on the common stock and the earnings for the first half of 1919 have been substantially the same as in the first half of 1918.

"Your company is engaged in a business capable, on conservative lines, of large expansion, the tire business both of passenger vehicles and trucks being a notable example of this. For the last two years your company has been unable to meet the demand for its tires and, notwithstanding its capacity has already been substantially increased, further construction has been authorized which will require in the neighborhood of $15,000,000 for its completion and which will double the present capacity of the company for producing tires. The amount of present outstanding common stock, compared with the property of the company, is relatively very small.

"In view of these conditions your chairman would recommend, upon the certificate of organization being amended as proposed, that $36,000,000 of additional common stock be issued and offered to our common stockholders at par in order to provide ample capital to meet the enlarged business of the company without the application of so large a proportion of earnings for that purpose as has been done the last few years.

"Your chairman is also of the opinion that the company is now amply justified in placing its common stock upon an 8% dividend basis and he would, therefore, recommend that dividends at the rate of 8% per annum be paid upon the common stock of the company beginning in October next, and further that an extra distribution either in stock or in cash, such as may be warranted under all conditions, be made early in 1920 to common stockholders."

July Charters for Banks.

The office of the Comptroller of Currency announces that during the month of July 20 charters for new national banks were granted and 54 applications for increases of capital of existing national banks were approved.

California Company to Issue Notes.

The Sierra & San Francisco Power Co. has asked the Railroad Commission for authority to issue five notes of the face value of $30,000 each to the United Railways Investment Co., the notes to be secured by the pledging of bonds of the face value of $200,000. The United Railways Investment Co. has offered $140,000 for the notes, and the Sierra company seeks authority to make the issue on the ground that it has been unable to dispose of the $1,000,000 of bonds authorized by the commission in May, 1918. The petition shows that the indebtedness of the company, other than the bonded indebtedness, is for current expenses and advances from consumers amounting to $164,544.03, and that the proceeds of the note issue are to be used for improvements at the Stanislaus power plant and other betterments.

Erie Lighting Stock Issue.

Paine, Webber & Co., Chicago, is offering 7% cumulative preferred stock of the Erie Lighting Co. at 92½ and accrued dividend to yield 7.57%. The Erie Lighting Co. serves a population of over 120,000 in Erie, Pa., and adjacent territory, with electricity for lighting and power purposes and does a steam heating business in Erie. The company has an installed capacity of 32,000 hp. contained in two stations which have been erected within the past six years, one of which, with an ultimate capacity of 65,000 hp. has just been completed. This utility is making gross earnings of over $1,000,000 and is showing more than 20% earned on the preferred stock after payment of all expenses.

Cumberland Valley Company Elects Officers.

At the recent annual meeting of the directors of Cumberland Valley Telephone Co., held at the offices of the company, 227 Walnut street, Harrisburg, Pa., the following officers were reelected for the ensuing year: President, William J. Lescure; vice-president, John C. Motter; secretary and treasurer, O. K. Kines; and general manager, Cameron L. Baer.

Illinois Commission Authorizes Note Issues.

The Illinois Public Utilities Commission has authorized the Decatur Railway & Light Co., Decatur, Ill., a subsidiary company of the Illinois Traction System, to issue promissory notes to the amount of $40,698. The Commission has also approved a promissory note issue of the Quincy Railway Co., Quincy, Ill., another subsidiary of the Illinois Traction System, in the amount of $104,919.

Clinton Wright Wire Stock.

Liggett & Drexel and Knauth, Nachod & Kuhne companies have formed a syndicate to purchase and resell 70,000 shares of common, $50 par, of Clinton-Wright Wire Co. The stock is being offered for public subscription at $36 a share.

United Light & Railway Surplus

Surplus earnings of the United Light & Railway Co. and subsidiary companies for the 12 months ended April 30, after payment of dividends at 6% on the first preferred, amounted to $509,658 for 1919, an increase of $15,209 over 1918 period. Reported figures of United Light & Railways Co. for four months to April 30, 1919, showed an increase of $61,276 after preferred dividend.

This improvement in surplus is qual to .89% on the 4% common stock, and compared with a surplus of $128,152 for the four months period, an increase of 47.81% over four months to April 30, 1918.

Statement of earnings of United Light & Railways Co. and subsidiaries for the 12 months period ended April 30 follows:

	1919.	1918.
Gross earning	$9,659,547	$8,232,303
Net after taxes	2,858,574	2,729,802
Balance, app. to Un. Lt. & Rys. Co.	1,955,486	1,836,610
Bal. after int. chgs.	*116,730	1,101,378
Surplus after pfd. div.	509,658	494,449

*Interest on notes and commercial loans increased $132,258 and decreased $29,447 during this period.

Earnings.

WISCONSIN EDISON.

Electrical Review

Vol. 75. No. 8. CHICAGO, AUGUST 23, 1919 Three Dollars a Yea

This is the famous Hughes "50" Electric Range. Last year alone more than 10,000 Hughes Ranges went into service.

The Hughes Range installations last year brought to Central Stations nearly half a million dollars' additional revenue. A revenue producer like this is entitled to full consideration by Central Station men.

The Hughes Range is the logical Range to put onto your lines, for Hughes advertising and Hughes sales cooperation are factors the Central Station man cannot afford to overlook.

Let us go to the bottom of the Range situation with you.

Write our nearest office now.

See our display of Ranges and other electrical home equipment at the Electrical Shows:

Electrical Review

WITH WHICH IS CONSOLIDATED WESTERN ELECTRICIAN AND ELECTROCRAFT.

VOL. 75—No. 8. CHICAGO, SATURDAY, AUGUST 23, 1919. PAGE 301.

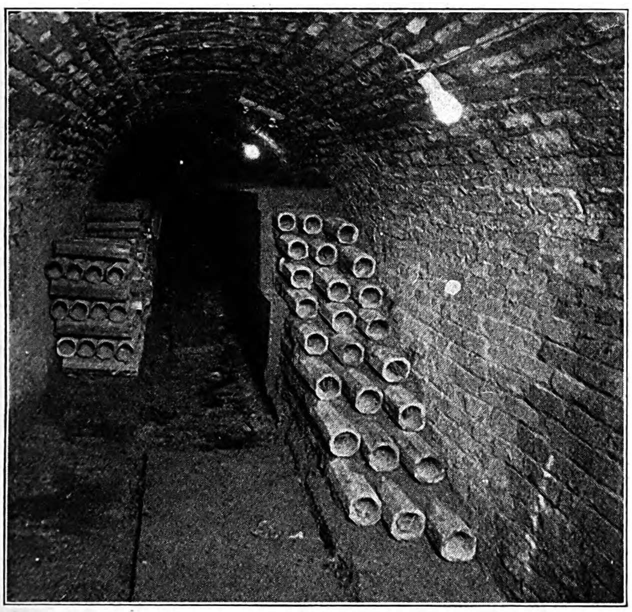

Fig. 1.—Brick Tunnel Showing Conduit in Course of Being Laid.

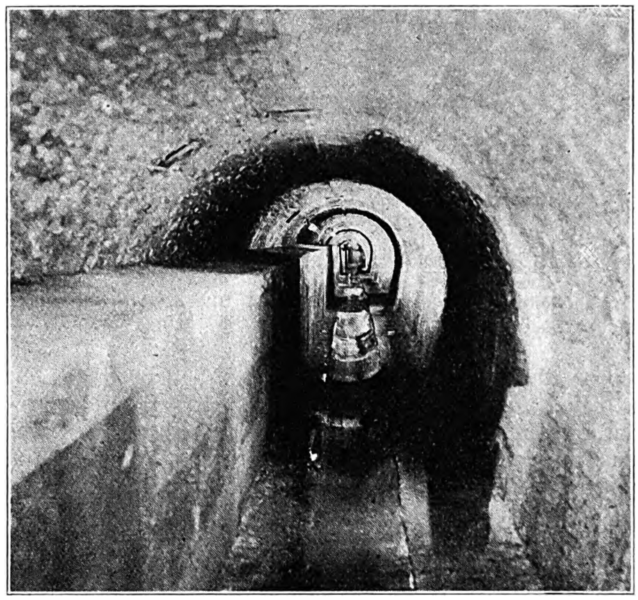

Fig. 2.—Duct Line Laid and Cemented in Tunnel of Concrete.

Conduit Construction in Telephone Cable Tunnels

Interesting Features of Latest Tunnels Adopted by the Chicago Telephone Co.—Construction Methods Employed

CHICAGO is traversed by the Chicago river, which follows a winding course through the city. The electric power and telephone utilities have found that the use of submarine cable where the river has to be crossed is unsatisfactory in the ordinary way because of the great likelihood of these cables being torn up, with resultant service interruptions and high cost of maintenance. The result is that both the telephone and light and power companies have resorted to the use of tunnels for their trunk cables or cable routes, as being a sound solution to the problem and one that guarantees safety to service and eventual economy of investment.

In the ELECTRICAL REVIEW of June 21 appeared an article by G. B. Springer on the construction of tunnels by the Commonwealth Edison Co. This article dealt with the reasons why tunnels have been adopted in preference to any other method, financial gains and structural details.

The Chicago Telephone Co. also has constructed several tunnels for its 300, 600 and 900-pair cables where the Chicago river has to be crossed. While the problems encountered by the telephone company were similar and almost identical to those that represented themselves to the power company, described in the issue of June 21, certain features of the tunnels for the telephone cables are different to those already described and a number of interesting features are brought out here.

The average length of the tunnels is about 700 ft. and their depth beneath the level of the sidewalk varies from about 80 to 90 ft. Some of the older tunnels are constructed of brick, but all the later ones are built entirely of concrete. The wall of these is 9 in. minimum thickness, about 6.5 ft. in height and 6 ft. in width. Allowing for the space occupied on both sides of the tunnel by ducts, a space of about 3 ft. 6 in. is available between ducts for persons to walk through the tunnel. The tunnel bottom is finished smooth with a grade one way to afford natural drainage. At the end of the tunnel having the lower level a sump pit is built. In this way it is an easy matter to empty a flooded tunnel of water by merely lowering a pump down the shaft to the sump pit.

The material was handled by lowering the ducts in a box made for the purpose. The box was supported by ropes fastened to each corner with a safety sling to a hook on the end of a three-quarter-inch line operated through a snatch block rigged to a derrick at the

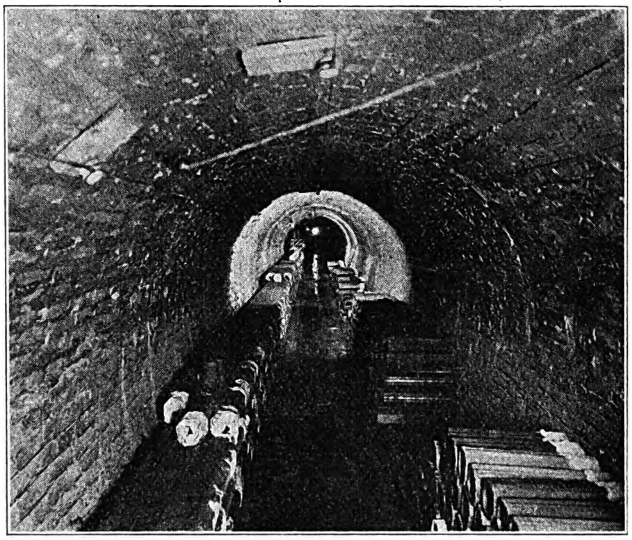

Fig. 3.—Conduit Stacked Ready for Use. Cheesecloth Is Used to Prevent Ducts From Being Clogged Up During Assembly.

top of the shaft. Sand, gravel and cement were sent into the tunnel by means of a wooden chute and material for the use of the construction through the river was mixed on the floor of the tunnel, opposite the point required. The concrete for the tunnels were mixed by hand in the tunnels. The concrete for the lining of the shafts was mixed above ground.

Details of Shafts.

The shafts leading to the tunnels are circular and all are built of concrete, the thickness being 13 in. minimum. The method employed for building these shafts depended upon the nature of the ground passed through, which was at different times quicksand, rock, clay, etc. All shafts are 6½ ft. inside diameter.

A galvanized iron step ladder was built into the shaft as it was lined with concrete, as also were 3-in. angle irons placed every 3 to 4 ft. on opposite sides of the shaft to serve as supports for the vertical duct lines. The distance between these angle irons is about 2½ ft., being therefore amply sufficient to permit a man to pass down the shaft into the tunnel. As the tunnels have been built with sufficient capacity to care for future growth, only the vertical ducts or risers on one side of the shafts have been installed to date. The opposite, or empty, side is covered at the top by a safety grating of cast iron which prevents persons falling down the shaft through the space that will eventually be occupied by conduit.

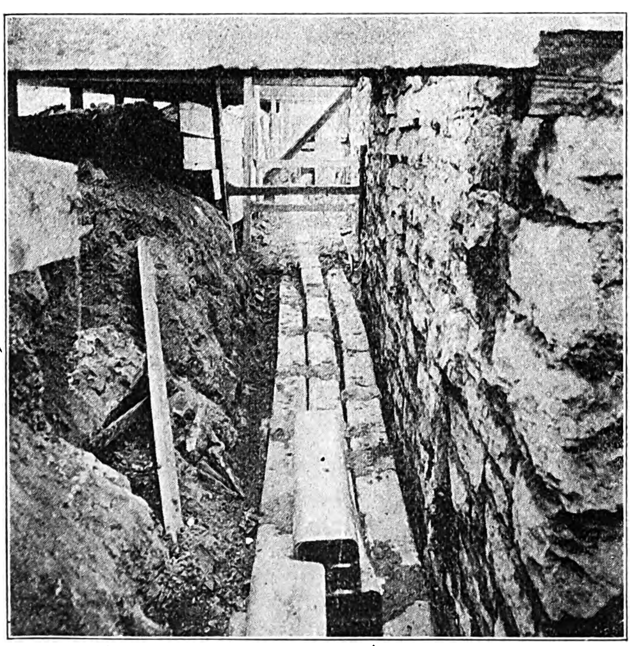

Fig. 4.—Four-part Duct as Used in Horizontal Duct Line After Single Duct Emerges From Riser From Tunnel.

Conduit Construction.

The floors of the tunnels were leveled in order to provide a straight foundation and treated with a cement mortar for the first layer pipe, which was constructed with the use of a wooden mandrel with all joints in the different rows staggered and each joint wrapped with cheese cloth to prevent any foreign substance from entering the pipe. The bottom row was laid for about 100 ft. with the next rows in rotation, until all rows were installed, when the concrete form was built and concrete placed. The conduit is covered with a 3-in. covering of cement. After the completion of the conduit through the bore of the tunnel each pipe was rodded, swabbed and fish wire installed.

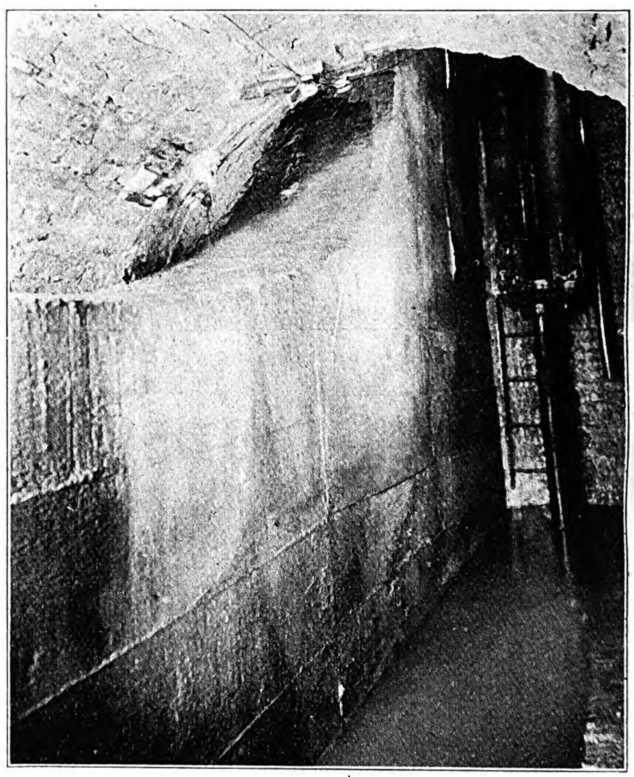

Fig. 5.—Duct Line Where Horizontal Run Changes to Vertical. View Taken of Lower Tunnel Level, Showing Collection of Drainage and Emerson Pump.

The work of building the foundations for the radius curves was next in line. This involved considerable care to provide the proper radius for the bends, which were installed with the straight pipe and a perfect radius provided. The shortest radius adopted was 10 ft. 6 in., and the largest about 14 ft. 6 in.

The construction of the riser pipes in the shafts necessitated extreme care and in order to prevent any substances from dripping on the pipes, they were plugged after each section was placed. As this work progressed, the first wire was drawn through until the job was completed, when these wires were replaced with No. 9 galvanized iron wire, after a thorough swabbing, and all ducts provided with wooden conduit plugs.

For the vertical sections or risers, the ducts are placed in position by a mandrel, which consists of a wooden rod 12 ft. in length upon which the sections of duct were threaded or strung. This assured perfect alinement of the ducts and reduced the time of building the vertical sections. Three-inch angle irons are built into the shaft every 3 to 4 ft., and to these the wooden forms are fastened after which the concrete of a mixture of one part cement, three parts gravel and five sand, is poured. Wooden forms were used for filling in and covering in the ducts. Wooden forms were, in fact, used throughout the job.

The ducts are laid three wide and 8 to 10 ft. high. The ducts are of vitrified clay with an inside diameter of about 4 in. The company in the past and for usual underground work has employed the multiple duct. However, for the work such as tunnels it has been found that the single duct is far more preferable. With multiple duct it would have been practically impossible to make the curves required at the vertical or risers with the multiple duct and castings would have had to be employed at these sections.

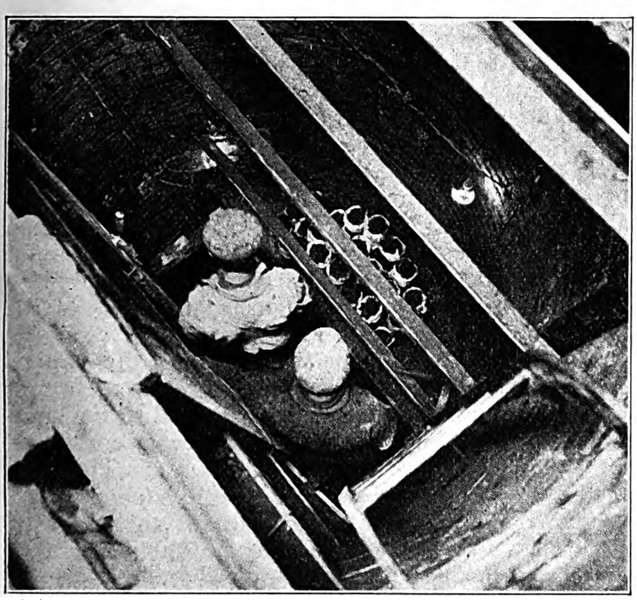

Fig. 6.—View Looking Down Brick Lined Shaft Showing Location of Ducts Ladder and Angle Irons.

Moreover, with multiple duct only six 4-duct elements could be used, holding 24 cables, whereas by employing single duct 30 cables can be carried on one side of the tunnel.

The decision of the company to use vitrified clay duct instead of iron pipe, as had been used previously in the company's former tunnels, was that iron pipe has been found quite objectionable in many ways. To begin with, iron pipe subjected to such conditions as exist in tunnels, where corrosive liquids and gases are ever present, corrode rapidly. Corrosion of the pipe occurs and also electrolytic action between the iron pipe and the lead cable sheath. Rust from the upper surfaces of the interior of the pipes falls down to the bottom, causing clogging of the pipe, which introduces difficulties when the time comes to pull out the old and pull in the new cable. At the risers it has been found that the rust from the vertical portions of the risers falls and collects at the bottom of the vertical, here also causing collection, rusting together and trouble.

WAR DEPARTMENT ANNOUNCES SALE OF CARTRIDGE CASES.

Rejected Cases Are Especially Suitable for Lamp Shades or Bases.

The Director of Sales of the War Department has announced a sale, at 20% above the current market price of their metal content, of 1,500,000 brass cartridge cases not suitable for military purposes. These cases are especially adapted for souvenir and novelty purposes and can be easily converted into lamp shades, lamp bases and similar artcraft articles.

The offering includes artillery cases of the following sizes: 75 mm., weight 2.61 lbs.; 4.7 in., weight 8.25 lb.; 6 in., weight 7.03 lb.; 3 in., anti-aircraft, weight, 6.75 lb. The metal content of the cases is approximately 70% copper and 30% spelter.

The 75-mm. cases are located at Providence, R. I., Breckenridge, Pa., Mays Landing, N. J., and South Amboy, N. J. The 4.7-in. cases are located at Burneage, Mass., Waterbury, Conn., and South Amboy, N. J. Prospective purchasers are requested to communicate with the Ordnance Salvage Board, 6th and B streets, Washington, D. C., or the Salvage division, Purchase, Storage and Traffic Division, Munitions building, Washington, D. C., or the Surplus Property Officer, Zone Supply Office, in any of the larger cities.

TELEPHONE FACILITIES IN NEW YORK TO BE IMPROVED.

Important Construction Work Now Under Way to Improve Service.

In connection with hearings being held by Public Service Commission as to the adequacy of the telephone service given by the New York Telephone Co., F. H. Bethell, vice-president of the company, in a recent letter addressed to the Commission, sets forth that the service has been seriously disorganized by war conditions, and that at the present time there should be in the New York City plant no less than $25,000,000 in additional construction to properly handle the city's traffic. It is pointed out that important new construction is already under way, including a new central office building in the Bronx, two in Brooklyn, and the installation of complete new switchboard units in four Manhattan central stations and one station in Queens. Also plans have been arranged for extensive additions to existing switchboard equipment for five Manhattan, six Brooklyn, one Queens, and one Bronx central station.

TRADE EXPERT TO VISIT LESSER ANTILLES AND HAITI.

C. Grand Pierre, West Indian trade expert of F. C. Luthi & Co., 277 Broadway, New York City, left recently for the Lesser Antilles and Haiti. One of the purposes of his trip is to continue negotiations for the organization of public utilities, including electric lighting plants, a telephone system, etc., in these places.

The company has unusually strong personal connections with the prominent people of these islands and Mr. Pierre will look into the advisability of negotiating for quite a number of public utilities which the company has in view as possibilities. The company is also preparing for some work in South America where it maintains its own offices.

Central-Station Rates in Theory and Practice

Seventh Article—The Consumer Cost, What It Includes and How It Varies—Determining the Numerical Values of the Three Elements of Cost—Analytical Valuation of Costs

By H. E. EISENMENGER

This is the seventh article of this series, which began in the issue of July 12 after a general outline in the issue of July 5. The present article concludes a discussion of the cost of central-station service, which has included detailed consideration of the three principal elements of the cost—energy, demand and consumer cost, the latter being treated in this present installment. In the next article will begin Part II of this series—The Price of Electric Service—Rates. The preceding articles have thus served as an important preliminary to the main body of the text, which will be continued weekly throughout practically the remainder of this volume.

PART I—THE COST OF ELECTRIC SERVICE—Continued.

II-A. THE THREE ELEMENTS OF COST.

3. THE CONSUMER COST.

A. CAPITAL CHARGES.

SECTION 54. There is a certain amount of money to be invested by the electric light and power company for every consumer individually over and above the capital which is invested for the consumers collectively in the central station and in the distribution lines. A large part of this additional investment is occasioned by the bare fact that the consumer is connected to the lines and this part has practically nothing to do with the amount of electrical energy consumed by the customer or with his maximum demand. It amounts to the same for a large consumer and for a small one. To make this clear, consider the following: It is general central-station practice that most equipment up to and including the consumer's meter is paid for by the electric light company, whereas the interior wiring proper, beginning behind the meter, is paid for by somebody else, usually the house-owner or the consumer. There is, therefore, a certain capital invested by the company for every single consumer individually. This consists in the cost of the so-called service wires or drop wires, that is, the connection from the street lines to the building and into the main service cutout; moreover, it includes the cost of the meter, etc. Up to a certain size of consumer this investment will be practically constant per consumer and above that size we can regard it as composed of two parts: A constant part (cost of average length of service connection, if constructed with minimum size of poles and minimum thickness of service wires; also cost of minimum size of meter, etc.) and another part proportional to the maximum demand of the consumer. Apportioning the capital charges of this latter part to the demand cost, we see that we have a certain investment left which is independent of the size of the consumer and therefore we will also have certain annual charges which are independent of the size of the consumer.

B. OPERATING EXPENSES.

55. Moreover, there are direct annual expenses, apart from the expenses caused by the capital investment, which also amount to substantially the same sum per customer, whether he be a large or a small one. Thus the electric light company generally has to send out a meter reader every month to every customer to read the amount of kilowatt-hours consumed during that month and then the company's clerks have to figure out the amount of his bill. They have to write out the bill, send it out to the customer, keep their records whether and when he has paid and more such clerical and bookkeeping work. In addition to this are the costs of maintenance and repairs to the service lines and meters, etc.

56. All these expenses, including the capital expenses for meter, etc., are caused by the mere fact that the respective consumer is connected to the company's lines and they are the same for every consumer, that is, they are *constant per consumer*. They are called the "*consumer cost*" or the "*customer cost.*" To give the beginner a rough idea of the order of magnitude of this amount, it may be stated here that different companies figure it somewhere between 50 cents and $1 per month for every customer. This is negligible in case of large consumers, who are paying a hundred or several hundred dollars per month. But it constitutes a very large percentage of the cost of serving the small consumer, whose monthly bill is perhaps somewhere between $1 and $5, or even lower.

C. INFLUENCE OF THE CONSUMER COST ON THE TOTAL COST PER KILOWATT-HOUR.

57. It has been mentioned before (Section 10) that it is frequent practice to reduce the total cost (and also the price) of serving a customer, to the unit of kilowatt-hours consumed by him, that is to say, the cost (or the price) of electricity is so much *per kilowatt-hour*. It is now clear that the total cost of serving the small consumer, per kilowatt-hour, is very much greater than that of serving the larger consumer in consequence of the fact that the consumer cost is constant per consumer. If the customer cost is, for instance, $1 per month per consumer, the cost per kilowatt-hour caused by a consumer who is using only 10 kw-hr. per month, *must* exceed 10 cents per kw-hr., since 10 cents per kw-hr. are necessary to cover the item of the customer cost alone. If the consumer is

using 10,000 kw-hr. per month, the customer cost per kw-hr. will be 0.01 cent, that is, practically negligible, and the cost per kilowatt-hour will be as low as other circumstances will permit.

D. VARIATIONS OF THE CONSUMER COST BETWEEN CONSUMERS.

58. Of course, the consumer cost per consumer although being approximately constant is not quite *strictly* constant, no more than the demand cost per kilowatt, or the energy cost per kilowatt-hour, are *strictly* constant.

If, for instance, a building is located far back from the street (where the distribution lines are run) the service lines from the street to the house will have to be longer and therefore more expensive than the average and perhaps we may even have to put up an extra pole or two for the service line. It has been shown before (Section 51) that the demand cost will be higher if the building is located in a thinly settled part of the town (which is particularly true in case of residences). Likewise, the customer cost in such districts will be higher because the meter readers, trouble men, etc., of the company will have to walk or ride so much longer from one customer to the next and therefore will not be able to cover as many customers in a day. This will apply particularly to residences in poorer districts where not every house is connected to the lines and also in some very fashionable quarters where every house is surrounded by a large garden. Furthermore, in case of residences, these employes of the electric light company will have to call twice or oftener in a certain percentage of the houses because they found the door locked and nobody at home on their first visit. This second visit is, of course, more expensive than the first one because the meterman may have to go quite a distance out of his way to reach the single house where he could not get access the day before. On the other hand, in case of "commercial customers" (this term means business enterprises) the meterman can be sure that he can get access to the premises and the meter at any time of the business day.

These differences between the customer cost of various customers are as a rule only small; an attempt to take all these small variations into consideration would generally hopelessly complicate matters and bring very little gain, just as in some cases of the variations of the energy cost and the demand cost, as already explained.

B. THE DETERMINATION OF THE NUMERICAL VALUES OF THE THREE ELEMENTS OF COST.

59. To determine for practical purposes the three items of energy cost, demand cost and customer cost, we can proceed as follows: We see from the company's books how large the expenses have been in a certain year under the various headings, for instance, for fuel, attendants' wages in the power house, salaries of the clerical forces, and dozens of other headings. We also know the value of the various parts of the plant, the life to be expected from them, etc., and consequently we can find the annual capital charges for those various parts. Now we distribute these various items of annual expenses by our best judgment under the three headings of energy cost, demand cost, and customer cost. For instance, 90% of the fuel cost may be assumed to go to energy cost and the remaining 10% to demand cost. The wages of the meter readers will go to customer expense and a certain percentage of the salaries of the clerical force goes to the same item. An intelligent scrutiny will generally give a pretty definite idea just how much of the time and the salaries has been devoted to the making out of the bills and similar work which goes to customer cost. Other expenses will be more or less in the air as far as that is concerned, for instance, the directors' salaries, advertising expenses, etc. It is plain that there is a certain element of arbitrariness in the whole procedure, but this element is smaller than would appear from this description. A large part of the cost can be assigned without much doubt to one or the other of the three items and only a moderate percentage remains questionable and has to be squeezed in somehow. After we have thus determined the total amount of each one of the three items of the cost, it is easy to divide them by the total energy consumption in kilowatt-hours, by the maximum demand in kilowatts and by the number of customers, respectively, to get the three unit costs. Corrections will then have to be made to allow for the diversity-factor, etc., as shown above.

60. As has been pointed out just now, there is in this method a certain element of uncertainty and arbitrariness about the apportionment of certain parts of the cost. We can remove this uncertainty in theory, and under certain conditions greatly reduce it in practice by a method which may be roughly characterized as taking into consideration the changes which the energy consumption, plant capacity (peak load) and number of consumers of the central station have undergone during the last few years and bringing them into connection with the simultaneous changes of the total yearly expenses. In this manner we arrive at the average values which the three headings of cost have had during the period under consideration.

This method, which implies the use of a little simple mathematics, was first proposed by the present author in 1914. An abbreviated reproduction of the original article in which this method was first put forth in this country by the author is contained in Insert VIII.

61. The preceding sections contain quite a lengthy theory of the cost of electric service and of the methods by which we can arrive at the figures for that cost. The author does not wish to convey the idea thereby that such scientific methods are generally employed by the central-station companies. Many of these companies, especially the smaller ones, are using to this day crude methods to learn what their unit costs are. We still frequently find the statement that the cost to the central station of service is so much per kilowatt-hour. This is a very convenient and intelligible statement, but—except in some special cases, where the governing conditions of service are known—it is not at all adequate. It will not be denied, however, that larger and well managed companies are employing much time and work on ascertaining their unit costs—time and work which are generally well and profitably spent.

Insert VIII—Appendix to Section 60.

NUMERICAL EVALUATION OF THE THREE ELEMENTS OF COST.

(Contains considerable mathematics in the proof, but the results contain only elementary algebra.)

This method was published by the author for the first time in English in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN of Aug. 15, 1914, of which article the following is a portion (modified to tie in with the rest of this series).

1. Calling c_1 the unknown customer cost per customer per annum,
c_2 the unknown energy cost per kw-hr. consumed,
c_3 the unknown demand cost per kw. of peak

responsibility or rather of "equivalent demand" (see Insert VI).

d the peak responsibility or the equivalent demand, respectively, of a certain customer,

e the same customer's yearly energy consumption in kw-hr.,

k the (unknown) total cost of serving that customer per annum,

we get the following equation:

$$k = c_1 + c_2 e + c_3 d \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Adding these equations for all customers of the central station (considering the central station itself as a customer also, as far as its home consumption of electric service is concerned) we get

$$\Sigma\,(k) = c_1 N_1 + c_2 \Sigma\,(e) + c_3 \Sigma\,(d) \quad \ldots\ldots\ldots\ldots (2)$$

where N_1 is the total number of customers served in that year.

$\Sigma\,(k) = K_1 =$ total annual cost of the central station.

$\Sigma\,(e) = E_1 =$ total energy consumed annually in kw-hr.

$\Sigma\,(d) = D_1 =$ sum of the customers' peak responsibilities (which is equal to the sum of the customers' equivalent demands, see Insert VI, and to the central station's peak load, neglecting, in the latter case, the losses in transmission, transformation and distribution).

We have thus

$$\left.\begin{array}{l} K_1 = c_1 N_1 + c_2 E_1 + c_3 D_1 \\ \text{for the following year we find} \\ K_2 = c_1 N_2 + c_2 E_2 + c_3 D_2 \\ \text{and for the third year} \\ K_3 = c_1 N_3 + c_2 E_3 + c_3 D_3 \end{array}\right\} \ldots\ldots\ldots\ldots\ldots (3)$$

In these equations the values of K, N, E and D are known and we have, therefore, three linear equations for determining the three unknowns, c_1, c_2 and c_3. On account of the small number of the unknowns, any elementary method, such as the method of substitution or elimination, could be employed for solving the equations.

2. The following investigation will show, however, that the equations (3) can generally not be employed without further changes. The results of this investigation are expressed in simple algebra and readers who do not care to follow the author into the details of the investigation will find the simple results summarized in Section 4 *et seq.* of this Insert.

These investigations are carried out here with the help of the theory to determinants. Readers who are not familiar with determinants are referred to the author's article in the Electrical Review and Western Electrician of Aug. 15, 1914, where the same investigation is also carried out graphically with the same results.

3. The values of the three knowns are given by

$$c_1 = R_1/R, \quad c_2 = R_2/R, \quad c_3 = R_3/R$$

where R, R_1, R_2 and R_3 are the following determinants:

$$R = \begin{vmatrix} N_1 E_1 D_1 \\ N_2 E_2 D_2 \\ N_3 E_3 D_3 \end{vmatrix} \qquad R_1 = \begin{vmatrix} K_1 E_1 D_1 \\ K_2 E_2 D_2 \\ K_3 E_3 D_3 \end{vmatrix} \qquad R_2 = \begin{vmatrix} N_1 K_1 D_1 \\ N_2 K_2 D_2 \\ N_3 K_3 D_3 \end{vmatrix} \text{ etc.}$$

The theory of determinants shows that equations (3) cannot be solved by finite values if

$$N_1 : N_2 : N_3 : = E_1 : E_2 : E_3 : = D_1 : D_2 : D_3 : \quad \ldots\ldots\ldots (4)$$

because in that case determinant R becomes zero and the equations will be fulfilled either by $c_1 = 0/0$, $c_2 = 0/0$, $c_3 = 0/0$, or by $c_1 = \infty$, $c_2 = \infty$, and $c_3 = \infty$. In the first case the three equations are identical amongst one another, the problem is underdetermined, and in the second case the equations contradict each other.

The latter case (contradiction of the equations) cannot occur in practice if we take the correct figures, but the first case may take place. It is most improbable that equation (4) will be fulfilled accurately, that the number of customers will grow in exactly the same ratio as the energy consumption and the central station's peak load grows; this means in other words, it is highly improbable that the central station's load-factor E/D will remain absolutely constant and also the average energy per consumer E/N and the average peak responsibility per consumer D/N. But it may happen and it may even be expected to happen that the changes of these three ratios from one year to the next will be very small. This means that the values of the determinants R, R_1, R_2 and R_3 are small as compared to the values of the factors K, N, E and D of which the determinants are composed. The determinants consist of a number of positive and negative members, which will very nearly cancel if equation (4) is very nearly fulfilled; for instance, the determinant will be figured as $1857 - 1854 = 3$. A small percentage inaccuracy of one or more of the constituent members (for instance, 1860 instead of 1854) may, and generally will, result in a very large error of possibly several hundred per cent of the value of the determinant and may even result in negative values for c_1, c_2 and c_3.

Such inaccuracies are inevitable. For instance, the figures we get from the company's books for the annual cost are the amounts *paid* for materials, wages, etc., during the respective year, whereas they ought to be for this computation the cost of materials, etc., actually *used* during that period. That is not exactly the same. The company may have bought a certain amount of fuel, for instance, in one year and used not all of it in the same year, and, moreover, paid for it only in the following year. Or in a certain year a repair has occurred which is particularly expensive and is due to extraordinary circumstances or accidents, for instance a boiler explosion, etc.

4. The requirements of a sufficient variation of the load-factor, the energy consumption per consumer and the average demand per consumer are generally better fulfilled if, instead of three successive years, three months are chosen at different seasons since the load-factor in summer and winter, for instance, reaches entirely different values. The result is further freed from the influence of casual irregularities by choosing not, as assumed heretofore, only three such periods, but by extending the calculation over a large number of periods, such as 24 months, with the result that one obtains average values of a larger number of periods.

This results in 24 linear equations with three unknowns. There is, of course, in general no solution possible which satisfies all the 24 equations, but it is possible to find those values of the unknowns which satisfy the equations in the most accurate way, that is, with which the sum of the squares of the errors becomes a minimum, or in other words the most probable value. This is done by the method of Gauss which consists in the following:

Let the 24, or in general n, equations be (denoting the unknowns in the customary way as x, y and z):

$$\left.\begin{array}{l} N_1 x + E_1 y + D_1 z = K_1 \\ N_2 x + E_2 y + D_2 z = K_2 \\ N_n x + E_n y + D_n z = K_n \end{array}\right\} \quad \ldots\ldots\ldots\ldots\ldots (5)$$

Multiply both sides of the first equation by N_1, those of the second equation by N_2, etc., and add the equations which are obtained thereby:

This results in a new equation:

$$\begin{aligned} &(N^2_1 + N^2_2 + \ldots + N^2_n)\,x + (E_1 N_1 + E_2 N_2 + \ldots + E_n N_n)\,y \\ &\quad + (D_1 N_1 + D_2 N_2 + \ldots + D_n N_n)\,z \\ &\quad = N_1 K_1 + N_2 K_2 + \ldots + N_n K_n \quad \ldots\ldots\ldots\ldots\ldots (\mathrm{I}) \end{aligned}$$

This equation (1) is called the first normal equation. Now if we multiply the first one of equations (5) by E_1, the second one by E_2, ... etc., and add them again we obtain the second normal equation:

$$\begin{aligned} &(E_1 N_1 + E_2 N_2 + \ldots + E_n N_n)\,x + (E^2_1 + E^2_2 + \ldots + E^2_n)\,y \\ &\quad + (E_1 D_1 + E_2 D_2 \ldots + E_n D_n)\,z \\ &\quad = E_1 K_1 + E_2 K_2 + \ldots + E_n K_n \quad \ldots\ldots\ldots\ldots\ldots (\mathrm{II}) \end{aligned}$$

In an analogous manner we get the third normal equation by multiplying all equations (5) by D_1, D_2 ... D_n, and adding them thus obtaining

$$\begin{aligned} &(D_1 N_1 + D_2 N_2 + \ldots + D_n N_n)\,x \\ &\quad + (E_1 D_1 + E_2 D_2 + \ldots + E_n D_n)\,y \\ &\quad + (D^2_1 + D^2_2 + \ldots + D^2_n)\,z \\ &\quad = D_1 K_1 + D_2 K_2 + \ldots + D_n K_n \quad \ldots\ldots\ldots\ldots\ldots (\mathrm{III}) \end{aligned}$$

The three normal equations can be written in a shorter and more perspicuous way as follows:

$$\Sigma\,(N^2_m)\,x + \Sigma\,(E_m N_m)\,y + \Sigma\,(D_m N_m)\,z = \Sigma\,(N_m K_m) \ldots (\mathrm{I})$$
$$\Sigma\,(E_m N_m)\,x + \Sigma\,(E^2_m)\,y + \Sigma\,(E_m D_m)\,z = \Sigma\,(E_m K_m) \ldots (\mathrm{II})$$
$$\Sigma\,(D_m N_m)\,x + \Sigma\,(E_m D_m)\,y + \Sigma\,(D^2_m)\,z = \Sigma\,(D_m K_m) \;.\,(\mathrm{III})$$

It is seen that the 9 co-efficients of the unknowns are partly identical with each other in couples according to a law of symmetry which can be easily recognized. This makes their computation easier.

These three normal equations solved for the three unknowns x, y and z yield directly the most probable values for the latter, that is, the values which approximate most closely the simultaneous fulfillment of all the n original equations.

5. The charges found in the foregoing manner require a correction.

The kilowatt-hour charge must be increased in the ratio of kilowatt-hours generated to kilowatt-hours sold, since only the kilowatt-hours sold are paid for and not, as has been assumed heretofore, the kilowatt-hours generated.

On the other hand, the demand charge must be reduced because in practice it is based not on the "equivalent demand" of the customer or on his peak responsibility but on his individual maximum demand. The customers are classified and the ratio $\dfrac{\text{equivalent demand}}{\text{maximum demand}}$ or $\dfrac{\text{peak responsibility}}{\text{maximum demand}}$ is then found by measurements or by estimating to our best ability. The average of this value prevailing within every class of customers is then the reduction factor prevailing within that class.

6. The method described above is, of course, not restricted to the number of three charges as one can also aim from the beginning at the application of two charges only, for instance, a kilowatt-hour charge and a demand charge, and then one obtains only two unknown y and z (c_2 and c_3) in the equations. With such central stations which are also in the electric railroad operating business one could add two more unknowns to the three original ones, namely, u (that is, that part of the cost of railroad operation which is proportional to the number of car-miles) and v (that is, that part which is proportional to the length of track). It should be understood, however, that the calculation of five unknows out of about 24 equations is a rather lengthy operation even with the use of computing machines and it is probably preferable in all those cases to separate the railway cost from the beginning entirely from the rest of the cost, if possible. The expenses which are common to both branches, such as general expenses, must then be distributed arbitrarily to our best judgment between the two branches of the business. Each one of the two branches is then to be resolved into its parts according to the analytic method just shown.

7. As regards the length of the period over which the computation should be extended, it must not be too small so that accidents do not exert a disturbing influence and that a proper average can be found. On the other hand, it must not be too large since the amount of the cost for the different charges is slowly changing in the course of the years in consequence of the development of the central station (for instance, the use of more economical generators, etc.). Twenty-four monthly periods are about the proper figure under ordinary circumstances. If during that time a change of rates has occurred, this influences favorably the accuracy of the computation since thereby the character of the use of the current by the customers is changed. The load-factor or the average number of kilowatts or kilowatt-hours, or all of these factors, are liable to change and this, as shown above, makes possible a more exact computation of the unknowns.

(To be continued.)

POWER PRODUCTION AND FUEL CONSUMPTION BY UTILITIES FOR MARCH.

The following report is based on returns obtained by the Division of Power Resources, United States Geological Survey, from 3075 electric power plants engaged in public service, including central stations, electric railways and certain other plants, the output of which contributes to the public supply. The output for the month averages 101,400,000 kw-hr. per day, of which 41% was produced by water power. The average consumption of coal per kilowatt-hour of those plants using coal, was about 3 pounds.

THOUSANDS OF KILOWATT-HOURS PRODUCED.

Some Causes of Breakdown to Electrical Machinery

Deterioration of Insulation Due to Dirt, Mechanical Stresses, Etc.—Ventilation, Metal Fatigue, Bearings and Other Causes of Trouble—Typical Examples of Breakdowns Met in Industrial Plants

By W. C. WORRAL

In probably no other type of machinery are the causes of breakdown so numerous as in electrical machinery. The proper knowledge of breakdowns and their causes cannot be obtained only by a study of machines returned to the shops for repairs, but a full acquaintance with the conditions under which the machines operate is essential. A single breakdown may teach much, but when the same kind of breakdown is experienced many times deductive reasoning and a comparison of conditions and circumstances will generally lend to definite and accurate conclusions.

Dirt and Dampness Affect Insulation.

The vast majority of breakdowns have but one cause and no exact scientific knowledge is required to understand it. Dirt or, as it has been defined, "matter in the wrong place," is responsible and no precaution can be considered unnecessary which will prevent dirt obtaining access to the internal parts, such as the commutator, armature winding or field coils. Dampness, oil and dirt are the greatest enemies of insulation; dampness and oil are not so serious in themselves but the danger lies in their forming a conveying medium for all kinds of injurious matter.

A certain hydroelectric station was shut down for two years, the insulation resistance of the machines was practically zero and yet without any preliminary drying they were started up and put on load; after a few weeks' service the machines had an insulation resistance of infinity. These machines have since given years of service without any breakdown. Such a case is exceptional and is due to the fact that the atmospheric moisture was pure and the insulation had not suffered any deterioration.

The presence of dampness frequently causes repairs on the site to turn out very unsatisfactorily. The insulating materials may be dry when taken out of storage, but by the time they are put into the machine they are very likely to have absorbed moisture and the varnish is applied without "stoving." A very bad example of this kind occurred in a coal mine. An underground three-phase motor of 90 hp., 2650 volts, coupled to a pump broke down to ground in the stator and was repaired in position. The repaired coil broke down again in a week and as the owners refused to bring the motor to the surface, the repair was again effected in the pump chamber underground. A month later the repaired coil broke down once more and the owners then allowed the motor to be sent to the makers' works. A repair was again effected but under favorable conditions and no further trouble was experienced.

Where failure of insulation occurs, a green discoloration is sometimes observed near the point of breakdown and there seems little doubt that the discoloration is in some way associated with the failure. Chemical analysis shows that where the discoloration occurs chlorine is frequently present. One possible source of the chlorine is soldering flux. Zinc chloride has been found present in considerable quantities even in soldering paste which is guaranteed to be free from this substance. Ordinary soldering "spirit" is used in most shops for the purpose of cleaning the soldering iron and for tinning the conductor ends. A common practice is to dip the hot metal into the spirit, which splashes all round and it is quite conceivable that spots reach parts of the machine which are supposed to be entirely free from such materials. The green discoloration may also be due to the vegetable and fatty acids contained in the flexible varnish with which the insulation is impregnated. It is generally admitted that some action takes place during the process of oxidation of the varnish and even when the varnish has hardened further action may take place which may adversely affect the insulation that the varnish is supposed to protect.

Discoloration has been noticed more particularly in connection with built-up mica used in commutator construction and in this case the discoloration is probably due to the methylated spirit used as a solvent of the varnish or cement employed in the construction of the material. It is practically impossible to make a chemical analysis of the green product as the quantity present is always too small.

A very remarkable series of breakdowns in which the green discoloration was noticed occurred in connection with two 300-kw., direct-current generators and a 100-hp., direct-current motor, all of which broke down in succession at short intervals in exactly the same way. The failure was in each case due to short-circuits between the commutator segments at the bottom of one of the V-grooves. There was no sign of any foreign matter present, but around each place where a short-circuit had occurred the micanite and the copper were discolored green. The short-circuits were most likely due to the action of the solvent of the varnish on the copper, but there was also the possibility of traces of soldering spirit or even soldering paste being present. The soldering paste used was found to contain zinc chloride and the micanite also showed traces of chlorine.

Although it is suggested that in many cases of breakdown the cause lies in the nature of the insulating materials, similar machines made of the same batch of materials at the same time do not all show the same defects. The 300 kw. generators and 100 hp. motor cited above were only three machines of a 600-kw. installation, comprising chiefly, motors of 10 hp. and upwards. The remainder of the machines proved satisfactory and other machines turned out by the makers at the same time were free from defect. This naturally throws some doubt on the conclusion that the fault was inherent to the materials, for the question is at once asked, why had not other machines failed in the same way? At the same time it must be admitted that the failure of three machines in the same way is better proof that the material was faulty than the survival of the other machines was proof that the material was good. No really conclusive explanation of this particular case was arrived at, but after rebuilding the commutators the trouble was not experienced again.

Bad Effects of Producer-Gas Fumes on Insulation.

Producer-gas fumes have a very bad effect on insulation. More than one person who should be an authority on the subject has stated that the fumes have no bad effect on the insulation and the only trouble is with the conducting deposit behind the commutator. This deposit is a very fair conductor, but the effect of the gas fumes on the cotton insulation is very serious. When the armature is wound it should be dried *in vacuo* and thoroughly impregnated with a flexible varnish; merely painting with varnish is quite inadequate. Some makers have tried impregnating with gum, which is very effective, but in the event of repairs being necessary the removal of a coil is a very difficult matter. Although the insulation may have perished, it may hold together for a considerable time but when one point gives way failures at many other points follow instantaneously. A 300-kw., 220-volt, direct-current dynamo was driven by an engine using producer gas. The insulation resistance of the field coils steadily diminished to a very low value; there was, however, no sign of any actual failure until suddenly all the ten coils burnt out together. The commutator of a machine subject to gas fumes becomes coated with a copper salt, probably a sulphide, which is sufficiently non-conducting occasionally to prevent a dynamo exciting.

Conducting deposits which lodge underneath the overhang of the armature conductors at the commutator end cause the greatest trouble where they form a leakage path between the bare copper ends of the conductors and the armature spider. Much can be done by insulating the conductors right up to the commutator lugs and by varnishing the metal, but a more effective preventive is to increase the length of the leakage path and exclude all crevices where the deposit may lodge. The actual way in which this may be carried out depends upon the design of the machine, but generally a sheet of press-spahn is laid between the armature conductors and the supporting ring, the sheet is bent over and tied to the spider arms. In this way a smooth inclined surface is provided upon which the deposit cannot accumulate. For insulation, mica or micanite should be used wherever possible, as these materials resist the action of the fumes better than cotton.

The precautions suggested will greatly improve the running of electrical machines subject to producer-gas fumes, but the most effective precaution of all is to ventilate the engine room in such a way that the fumes cannot reach the machines. There should be no opening in the wall between the producer plant and the engine room, or if an entrance is necessary the door should be opened as little as possible and made to close automatically. The ventilation should be so arranged that the inlet of fresh air is close to the generators so that the gas fumes do not pass over them. Most engine houses are arranged so that the mail door and windows are near the generators, but they act as inlet or outlet according to the direction of the wind; a fan should always be provided to ensure that the air currents flow in the required direction. In the absence of a fan, a ventilator in the roof directly over each generator is of great assistance in maintaining a good atmosphere round the machines.

The effect of chemical fumes generally is much accentuated by the presence of dampness and every precaution should be taken to keep the windings dry. When a machine is not in use, incandescent lamps should be kept alight inside the enclosing case and the windings should be frequently cleaned, "stoved" and varnished, if the machines are to be kept free from an abnormal number of breakdowns.

Conducting deposits behind the commutator are not always due to gas fumes but may come from the general dust in the atmosphere. Direct-current turbogenerators run great risk of failure in this respect and should whenever possible be provided with filtered air. In the power house of an iron works two 450-kw., 220-volt, direct-current turbogenerators running at 2250 r.p.m. were run for about 12 months without being opened up for examination and cleaning. Eventually the equalizing connections at the back end of the armature of one machine burnt out and a fortnight later the armature of the other machine broke down in the same way. On examination it was found that a mixture of coal and iron dust and oil had collected underneath the connections to the commutator and had set up short-circuits between the conductors. The coal dust was burnt to ash, but the insulation of the armature conductors was undamaged except where the burning had occurred. The equalizing connections, however, were of much smaller section than the armature conductors and had overheated and burnt out. It was found necessary to strip and completely rewind both armatures in order to fit new insulation at the back end. The strong draft of the generators had drawn in dust from the atmosphere and oil from the bearings, and the mixture had not only lodged behind the commutator but filled up the air gap solid and partly choked the outlet grids on top of the machine. After the accident, air filters were provided with very satisfactory results.

A low or high insulation resistance is not always a reliable guide to the real condition of the insulation. A machine may have a low insulation resistance and yet the insulation may be in excellent condition. The pores of insulating media cannot be so impregnated or coated with varnish as entirely to prevent the access of moisture, and all varnish cracks and opens out after a certain time. On the other hand, if moisture be absent, and there is no actual fault, a machine may have a very high insulation resistance and yet be in very bad condition owing to real deterioration of the insulation.

Effect of Mechanical Stresses on Insulation.

The insulation used in electrical machines is of necessity for the most part of a very flimsy nature from a mechanical point of view and although the machines may be designed so as to relieve the insulation of mechanical stresses to a very great extent, there are still stresses due principally to electromagnetic causes which seriously endanger the machine. Generally the stresses cause a slight movement when the load is suddenly changed or the current is switched on or off, and in time the movement causes abrasion of the material. This is particularly the case with field coils. In the old days the coils were wound on metal formers and the insulation was protected, but in most modern machines the coils are only taped around and wedged on the poles to prevent movement. When, however, a coil repeatedly expands and contracts, due to heating and cooling, it often becomes loose and on switching the field current on or off the coil is moved on the pole so that in course of time the conductor becomes grounded. If the coil is on the top of the machine considerable difficulty is sometimes experienced in detecting the fault, as when the machine is running (and cannot therefore be tested) the coil is lifted and the ground appears, while when the machine is stationary the coil is resting on the pole shoe and the ground disappears. The absence of the metal former has, of course, many advantages, but if it is discarded much stronger insulation should be used and the coils more effectively secured. Another weak point is found at the end of the armature slots; in some makes of machine the coils are bent round too sharply and the edges of the slot are not sufficiently insulated.

Troubles Due to Ventilation.

The power which a modern machine will develop is generally limited by the permissible temperature rise and the actual temperature rise depends upon the effectiveness of the arrangements for dissipating the heat generated. The problem is of very pressing importance in high-speed turbogenerators where the radiating surfaces are of relatively small extent. There is not much difficulty in ventilating the stator, but the rotor presents a more difficult problem. In some makes the air passages are radial while in others they are axial. Designs are, however, continually being varied and experience has not yet led to the general adoption of any particular method or design.

The air is forced into the rotor either by fans on the generator shaft or by an external motor-driven fan, and apart from the extra cost, the advantage seems to lie with the latter system. The higher efficiency of a properly designed motor-driven fan over the type of fan usually fitted on the generator shaft appears to compensate for the extra loss incurred in driving the motor. Many generators have fans which are very badly designed and finished, thereby seriously impairing the efficiency.

In the case of an alternating-current turbogenerator, the rotor of which seriously overheated, the fan on the generator shaft had an outer set of blades to supply air to the stator windings and partly ventilate the stator core, and an inner set which was intended to supply air to the rotor and through the rotor to the stator core. The effect of the rotor fan was tested by arranging baffles to cut off the action of the outer fan and it was found that practically no air passed through the rotor. This was no doubt due to grooves which were cut in the taper portion of the rotor shaft between the fan and the rotor to conduct the air but which apparently acted as fan blades in opposition to the fan fitted on the shaft. The result of this test was confirmed by the fact that when the generator was opened up the rotor ventilating ducts were found to be quite free from dust while the stator ducts were dirty. The difficulty was overcome by cutting away the fan and installing a motor-driven external fan which produced sufficient pressure to force the air through the rotor.

Wherever there is the slightest risk of dust entering a turbogenerator air filters should be provided. Even dry dust will become hard and closely packed under the action of centrifugal force and will fill up the ventilating ducts and interstices of the windings. The rotor of a 1500-kw., three-phase turboalternator running at 3000 r.p.m. completely burnt out due to the ducts and windings being choked with cement dust. Two air filters were in use, a dry filter in a room below the turbine and directly in the main air passage and a wet filter through which the air entered the room. All the air passed through the dry filter, but it was out of order and inefficient. The wet filter would probably have been satisfactory, but a door into the room was not sealed and was often open so that the wet filter was not fully in the air circuit. The whole arrangement was badly designed and of very little use.

The design of fan which is fitted to motors is often very weak mechanically, the blades are badly secured and are liable to break away from their fastenings. In the case of a 100-hp., three-phase motor that was pipe-ventilated the blades came out through the air outlet, having been thrown up a vertical pipe 6 ft. long, round a right-angle bend and along a pipe several feet before reaching the exit. A new fan was installed but the same thing occurred again; after this series of accidents the fan was redesigned.

Troubles from Faulty Core Construction.

One would hardly think it necessary to have to emphasize the necessity of thorough mechanical construction in connection with stator and rotor cores, yet a few examples will suffice to show that this is the case.

In a two-phase induction motor of 180 hp. the rotor core plates were clamped between two end rings by means of bolts passing inside but not through the core ring. The core was keyed at one point onto the rotor arms, but the end rings were secured only by small grub screws, half into the end rings and half into the rotor arms to prevent longitudinal movement. The rotor core was thus in the form of a ring which was entirely separate from the rotor arms or hub. Shortly after the motor was started up for the first time the rotor fouled the stator and considerable damage was done to several stator bars. On examination the rotor was found to be slightly eccentric and was ground true on the outside; the motor was re-erected, but the same accident occurred again and this time it was said to be due to a slight movement on the part of the pedestal bearings. After adjustment the motor ran satisfactorily again, but each time the motor was switched off a noise was heard which indicated that at a certain point in each revolution the rotor core moved on the hub. It was also noticed that when the rotor was hot a 6-mil feeler could be inserted between the core and the rotor arms in the region opposite to the keyway, but when the rotor cooled down the space was quite closed. It was evident, therefore, that the core was loose and this probably accounted for the apparent eccentricity of the rotor in the first instance. The rotor was properly secured to the hub by screws through the arms and into the end plates, and after this had been done all symptoms of looseness disappeared. It is interesting to note that the makers have since changed their design of rotor.

A 750-kw., 2200-volt, single-phase alternator running at 490 r.p.m. began to give a great deal of trouble within a few weeks of its erection. The tooth stampings of the stator in the neighborhood of the ventilating ducts and at the ends of the stator broke off, forming in course of time holes one or two inches long between the conductors; small pieces of metal came away while the machine was running and, being carried around in the air gap, caused violent sparks to be emitted; eventually the conductors at one point were grounded and a large hole was fused in the conductors in three adjacent slots and the two teeth between them. An attempt was made to improve the machine by painting the entire surface of the stator with shellac and plaster of paris and the holes as they occurred were filled in with the same material. The fault in this case was due to insufficient support of the stator teeth and it is quite probable that the entire stator core was loose. The distance piece in the core duct consisted of a thick stamping with the teeth twisted through a right angle. The method of repair adopted did not prove very satisfactory and later fiber wedges were driven into the ventilating ducts which proved successful in preventing further teeth breaking.

A three-phase, 750-kw., 440-volt turbogenerator running at 1500 r.p.m. after eight years gave serious trouble by one line of tooth stampings breaking off and grounding the stator bars on each side. It is quite possible that the trouble had been going on for some time, but it was not observed until the bars were grounded.

Some manufacturers do not appear to realize the necessity of providing effective support for the teeth of rotor and stator cores. The magnetic pulsations which occur do not exert any considerable force, but are of very high frequency and it is most probable that after a time the metal becomes fatigued and breaks off. The effects of fatigue are sometimes not apparent until the machine has been running for some years, as in the third example given above.

Core looseness is a frequent source of trouble in small machines, although it is so easy to avoid it by proper design and workmanship. Armature and rotor cores should always be built up on a cast-iron spider or sleeve, as this provides a much sounder mechanical construction than when the core is built directly on the shaft. Bad workmanship can, however, defeat good design and when shafts and spiders are packed in with strips of metal, as is occasionally the case, a loose core is only to be expected. The present-day method of securing armature and rotor cores by circumferential keys is generally satisfactory, but great pressure must be applied to the core before fitting the keys, and the keys must be a good fit. Some makers have not the requisite plant for this and are able to apply pressure to the core only with screw clamps. The keys in one 200-kw., direct-current machine dropped out and the core plates were held together only by the armature conductors. After running in this condition the conductors grounded to the core and on dismantling the fault was discovered.

Many manufacturers use a standard key and make up any slight variations in the length of the core by running in soft metal behind the key; this scarcely seems a workmanlike job.

Wood blocks are sometimes used as distance pieces in the core ventilating ducts: this is bad practice, as the wood is very liable to become loose.

Defective Connections.

The connections, external or internal, to a machine or switch are often very badly made and many serious accidents have resulted; a few examples will be given:

A 175-hp., three-phase induction motor supplied from a private plant in a mill, commenced to hunt and the hunting gradually increased in violence until the entire electrical system was surging, with the result that circuit-breakers tripped and the entire mill stopped. This occurred several times; the load on the faulty motor was then reduced and the hunting was kept within such limits as not to disturb other portions of the system. The trouble was found to be due to a bad connection in one phase of the rotor starting switch. The connection consisted of a projecting stud on which was placed a cable lug secured by two nuts. The inner nut had crossed threads and although tight, pressed on the lug in one part only and the locknut was on for only half its thickness. Overheating had caused the contact surfaces to become fused and eventually contact was practically broken.

A 70-hp., three-phase motor overheated considerably although three other similar motors doing similar work ran quite satisfactorily. The fault was found to be due to a contact in the star-delta starting switch, which was entirely missing so that although in star connection the motor was on the three phases of the supply, in delta connection one phase was cut out.

Two 600-kw. turboalternators running at 3000 r.p.m. broke down in succession after a few hours running, owing to the rotor connections breaking off close to the slip rings. The connections were not properly secured. The rotor winding broke down to ground some time later and when opened up it was found that, although the connections at the slip rings had been made secure after the breakdown, they were left quite loose inside the end bell and the insulation was almost rubbed away by abrasion against the inside of the fan casting.

Vibration and Fatigue of Metal.

Fatigue of metal is a very serious problem in the internal connections of an electrical machine. Vibration caused by lack of balance, loose foundations or relative movement of parts, sets up tremors which in course of time seriously weaken the metal. The most common occurrence is in the commutator connections of ordinary direct-current motors and dynamos, but many other more serious examples have occurred, a few of which will be given.

A 450-kw., direct-current turbodynamo running at 2500 r.p.m. broke down owing to a commutator lug breaking at a point about 1/8 in. inside the commutator segment; the lug was ripped off the upper armature connection but carried away a piece of the lower connection.

A 370-kw., direct-current turbodynamo running at 2500 r.p.m. failed repeatedly owing to the commutator lugs breaking at the corners. The lugs had sharp bends, but when new lugs without any sharp corners were fitted the trouble was not experienced again.

The exciter of a 750-kw. turboalternator running at 3000 r.p.m. broke down in the commutator, the copper segments cracked across and the lower part of the V of one segment broke off. The armature was badly balanced and the vibration was no doubt responsible for the breakage.

The rotor of a 125-hp., three-phase induction motor was wound with enameled strip copper: the overhanging end connections were, however, not mechanically secured, in fact were quite springy. The high-frequency rotor currents during the starting operation caused the copper strip to vibrate and in time a succession of breakages occurred. In later designs of this type of rotor winding the end turns are secured by wire threaded through them but even with this method some turns are often found loose.

The necessity for the security of terminal connections and other parts cannot be too strongly emphasized as very serious risk of breakdown and fire is often caused by faults in this direction.

An induction motor with a squirrel-cage rotor is usually considered a most robust piece of machinery, but unfortunately this very fact often causes the motor to be subjected to such arduous conditions of work and great abuse as no other type of motor would withstand, and as a result it is on the average no freer from breakdowns. Except in the more recent designs, the rotor is the weakest part. The contacts between the bars and the end rings become overheated and loose and the stator frequently burns out due to the increased current taken by the motor.

The modern methods of brazing the joints, casting solid or welding are all satisfactory, but soldering and riveting are of very little use. If the joints remain good, a rotor should never need rewinding, even if the insulation of the bars in the slots is all burnt away.

Bearing Troubles.

Bearings are frequently the cause of serious trouble. A seized bearing is often a small matter compared with the damage which follows. It is this which makes a phosphor-bronze bushing preferable to white metal, except in large machines which receive more attention and where the air gap is large enough to prevent any consequential damage. When the bearing heats up the white metal melts out and allows the rotor or armature to drop onto the stationary part and damage the windings, whereas a phosphor-bronze bushing seldom causes such damage. The bushing is more difficult to remove when seizure takes place, but that is not a serious matter. If the hot bearing is discovered in time and the machine is kept running while the bearing cools down, actual seizure may be prevented. Ball bearings are advocated by many makers, particularly for induction motors where the air gaps are very small, but these are not always very reliable in practice. While such bearings are suitable for steady drives where there are no sudden jolts, such as occur in a stone or ore crusher, they are supplied by some manufacturers for all purposes without any discrimination. The jolts usually cause broken balls and the only remedy is to substitute bushed bearings. Apart, however, from unsuitability under certain circumstances, one of the main troubles is in connection with the fitting of the bearings. The importance of this cannot be too strongly emphasized as carelessness is responsible for many breakdowns, and a repair usually involves a complete new bearing which is an expensive item.

Oil throwing is another bearing trouble and it seems curious that in a series of motors built to the same standard one will throw oil while the others may be quite satisfactory in this respect. The forces which draw the oil out of the bearing are of very small magnitude and the points to be observed in order to prevent the trouble would, to an inexperienced mind, seem very trivial. Oil throwing can be prevented and it is pleasant to find that the best class of manufacturers are now running no risks and take proper measures without first trying to do without them. Some machines seem to develop oil-throwing properties some time after they are put in service. This may be due to the special circumstances of the drive, such as the shape and size of pulley, the belt, arrangement of the ventilation; it may also be due to the nature of the lubricating oil, but is generally due to dirt on the oil-throwers. The presence of very little dust will allow oil to creep past the oil-throwers and the centrifugal action, which the oil-throwers are supposed to cause, is of no avail. Oil-throwers should be turned solid with the shaft, as if they are loose, oil will sometimes creep along the shaft under the oil-thrower.

Access to bearings during running is of great importance. Great carelessness is often shown in the arrangement of the pulley in two-bearing machines. The pulley often is so close to the bearing that the inspection hole is surrounded and the rings cannot be seen at work. At one works not only was this the case but the outer bearing was in a hole in a brick wall.

Care Best Preventative.

Case after case could be cited of costly breakdowns which might have been prevented by a little more care in connection with the bearings.

Some manufacturers do not take the trouble to make any inquiries regarding the conditions under which the electrical plant is to work, and many of the troubles which are experienced might be obviated if some attention were paid to suitability. It is often a question of price and the manufacturer may find it difficult to persuade a customer to pay extra for a more suitable machine or switch; but there are many cases in which price scarcely comes in and it is only a matter of thoughtlessness on the part of the designer of the installation. For instance, many excellent installations are considerably reduced in reliability by a poor quality of regulator in the exciter circuit, or a weak crossbar on a circuit-breaker; locknuts are usually left off the connections behind the switchboards; the springs on motor switches are often not securely attached; the handles on starting switches break off or become loose; switch and fuse contacts open and lose their springiness. Examples will, no doubt, occur to everyone and it seems a great mistake not to pay more attention to such matters.

The contract for the electrical equipment of a certain cotton mill contained a clause that if during the guarantee period the entire mill were stopped for a continuous period of two hours due to a fault, a heavy penalty could be enforced. The generator, cables, motors and motor switchgear were all of first-class quality; nothing in the workmanship was left to chance, yet the regulating resistance in the shunt circuit of the exciter was of the most indifferent quality. This resistance showed signs of overheating and as a precaution a second resistance of the same pattern was installed by the contractor as a standby. It was fortunate that the precaution was taken for one or other of the resistances failed several times, before a more robust piece of apparatus was supplied.

COLORADO STATE ROAD TO BE ILLUMINATED.

According to recent press dispatches, plans have practically been completed by the Colorado State Highway Commission for illuminating the road between Colorado Springs and Denver, Colo. This road is 75 miles in length and, according to the chairman of the commission, it will be the only one of its kind in the world when completed.

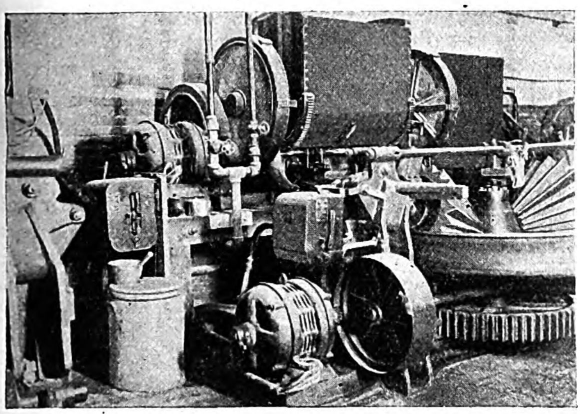
The Application of Electric Drive in Macaroni Plant

Features of Installation at Fould's Milling Co., Libertyville, Ill.—Advantages of Central-Station Service for this Work—Description of Process

By PAUL B. FINDLEY

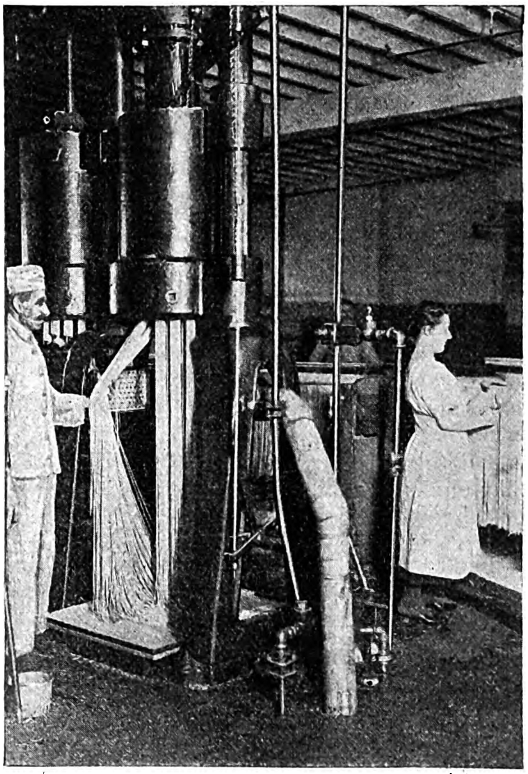
CONTRARY to the general impression, the process of making macaroni and other alimentary pastes is essentially one of manufacturing rather than baking. Moreover, the amount of power used in the process is considerable and easily adapted to the application of electric drive. On this account and because very little heat is required in the process which makes it desirable to purchase the electric service needed, central-station companies find such industries ready to adopt their service which usually proves profitable and advantageous to both, especially when the efforts of both are united to secure the most efficient and productive installation.

An interesting example of such co-operation between a central station and an industrial plant is that of the macaroni plant of the Foulds Milling Co., at Libertyville, Ill. When this plant was acquired, the Public Service Co. of Northern Illinois got the opportunity to make a study of the possibilities, and as a result complete electric drive was installed, nearly all the apparatus being individually driven and the installation has proven very satisfactory. As a bit of personal interest, it might be added that Glenn A. Hoskins, who engineered the work for the central-station company, later became manager of the plant.



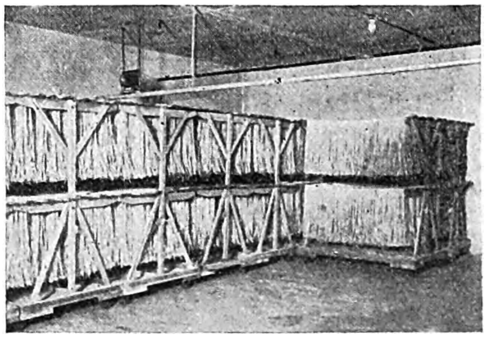
Westinghouse 15-hp. Motors Driving Mixer (Above) and Kneader (Below).

In this plant, the principal ingredient, flour, is received in barrels and taken up a conveyor to the sifting and storage rooms located on one of the upper floors. From this room it is run through chutes in appropriate quantities to the mixers on the floor below. Each mixer has two curved knives which, revolving, cut and fold the flour as water is added by the operator. When the mixing operation is completed, the dough is dumped into the pan of the kneading machine. This pan is turned under large toothed wheels, which knead the dough until all the lumps have been broken up and the mass is of uniform consistency. For these operations 15-hp. squirrel-cage motors are used on the newer mixing units and similar 10-hp. motors for the kneaders.



Macaroni Press at Fould's Milling Co. Plant.

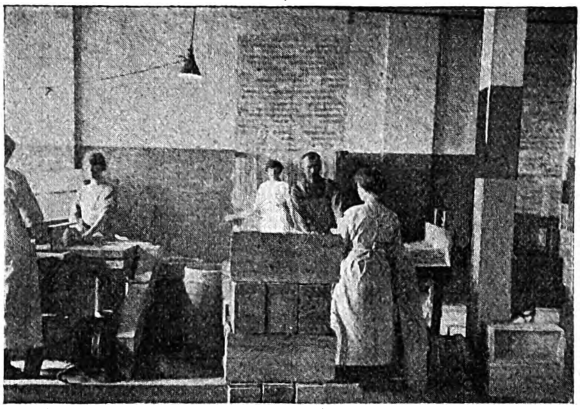
After it is kneaded, the dough is cut into blocks and taken to the presses where it is forced under pressure through holes, giving it the desired shape and size. Each of these presses has two cylinders, one of which is charged while the other one is under the press. In the bottom of each cylinder is a die-plate with the appropriate holes. In the cylinders a pressure of 3400 lb. per sq. in. is obtained. Oil is used in the press cylinders and the pressure is obtained from



Macaroni Drying Room at Libertyville Plant.

a battery of heavy duty pumps driven by a 30-hp. type CW Westinghouse motor.

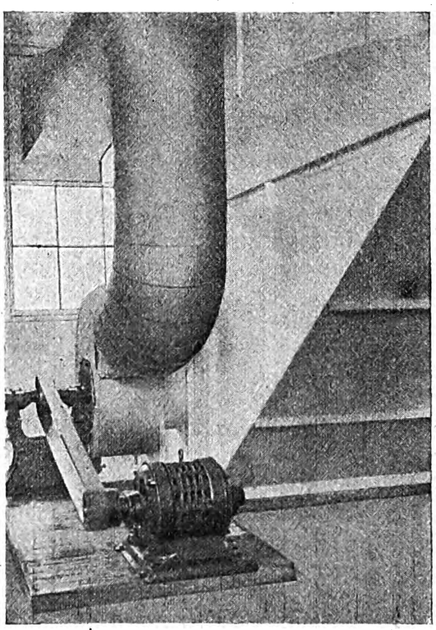
As the long strings of dough come out of the orifices, they are cut in suitable lengths and hung on wheeled racks which are then taken into the drying chambers. The drying operation is one requiring very close control of the humidity of the air. In the



Macaroni Saws Driven by Westinghouse Type-CS Motors.

drying rooms of the Foulds' plant it is secured by passing the air through a Carrier air conditioner. Motor-driven fans drive the air through a spray chamber and over heating coils; other fans exhaust it later from the drying rooms.

When the product is thoroughly dried, it goes to circular saws, each driven by a 5-hp. Westinghouse motor where it is cut in lengths suitable for packing. It is then sent in containers down a conveyor to the packing room on a lower floor. This conveyor is motor driven and arranged so that it can be operated

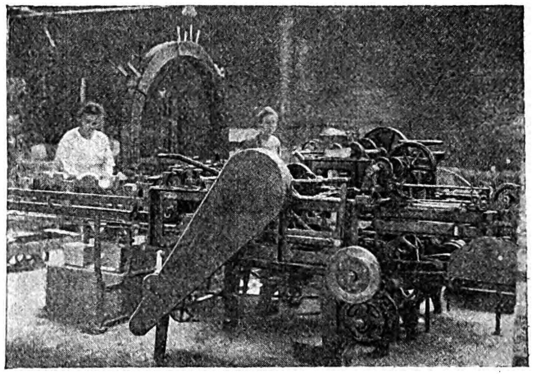


Motor Driven Exhaust Fan.

in the reverse direction to bring back the empty containers. The conveyor motor is controlled from either floor by three-way snap switches and a Westinghouse reversing-contactor panel.

The familiar yellow-and-red cardboard boxes in which the Foulds macaroni is sold are received flat and are opened and placed in automatic motor-driven box-sealing machines, of which three are installed. In these machines they are shaped, filled with the product—macaroni, spaghetti or noodles—and then sealed. They are then taken to the shipping room and packed in cartons for shipment. One sealing machine is driven by two 2-hp. Westinghouse motors; the other two by a single 5-hp. motor.

In the manufacture of noodles the process is slightly different. In addition to flour and water,



Automatic Box Sealer Driven by 2-hp. Motor.

eggs are also mixed into the noodle dough. The dough is rolled into a thin flat sheet and cut into ribbons by a gang of knives. Then it is further cut into shorter pieces which are placed on shallow wire trays. These trays are stacked one above the other in a conditioning room, over a wind box connected to the intake sides of several disc fans. Two such fan units are installed, each consisting of a Westinghouse motor belted to two fans. Each fan is in turn connected to three stacks of trays. An older form of dryer is served by a blower driven by a 5-hp. motor. This dryer is equipped with wire-bottomed drawers through which the air blows.

The electric power for the operation of this plant is furnished by the Public Service Co. from its 4000-volt three-phase lines through a bank of three transformers. The service used in the plant is three phase, 220 volts for power and three wire, 110-220 volts for lighting.

COST OF RUNNING ELECTRIC VEHICLE AT KETTERING (ENG.).

Municipal Truck Hauls Coal and Clinker at Cost of 46 Cents Per Ton.

A "G.V." electric vehicle of 3½ tons operated by the Kettering (Eng.) municipal electric supply department gave the following results for its second complete year's running, that is, from April, 1918, to March, 1919. The coal carted was 6839 tons and the clinker 1263 = 8102 tons. Cost per ton 46 cents; mileage 4392. The detailed figures for the year are as follows:

Depreciation, 10% on chassis less battery and tires, *i.e.*, $3900	$ 390
Increase at 5% on decreasing capital or 2½% on $3900	100
Current, 5958 units at 4 cents per unit	250
Tires, 4392 miles	85
Battery upkeep	500
Insurance	65
Wages (driver and mate)	2,050
Repairs, oil, etc.	485
Total	$3,925

NEW ELECTRIC AUTOMOBILE CONTAINS MANY NOVEL FEATURES.

Light Weight and Low Cost Promise Great Field for New Vehicle—Features of Design.

The coming "Ford" of electrics is the claim advanced by its manufacturers, Henry E. Dey, Inc., for the Dey Electric automobile. This car will be remembered by many as it created quite a sensation at the time of its introduction some years ago. At that time a company was formed for its manufacture and sale but very little was done. The new company was recently incorporated for this purpose and expects to put this machine on the market shortly.

The Dey Electric differs in many respects from any other electric automobile produced at this time especially as it is very light in weight and consequently much cheaper in cost. In order to cut the cost and weight of the cheapest and lightest electric now on the market in half, and at the same time not reduce the factor of safety or size of the car, which has the same dimensions as the Ford, it naturally follows that it must have many new features of design.

The most revolutionary change is in the motor and gearing. The motor has both its armature and field magnet rotatable, one element connecting with one driving wheel through a pair of reduction gears, while the other element connects in a similar manner to the other wheel. This arrangement produces a perfect differential substitute and, in addition to saving in its cost and weight, it is claimed to increase the capacity of the motor 100% for a given rotative speed. The reason for this is that the parts revolving in opposite directions cut the magnetic lines twice as fast, thus producing the results of a motor of double the velocity, which also adds to its electrical efficiency. The weight of the motor is still further reduced by placing the armature, which is a toothed Gramme ring, so that it surrounds the field. The field has six poles, all energized from one coil, and is especially designed for low field losses and light weight. The total weight of the field with shaft is less than 20 lbs. The total weight of the motor, which has a capacity equal to many heavier standard automobile motors is 51 lbs.

The commutator is of the face type, inclined at an angle of 10° in order that the brushes will have a similar inclination. The purpose of this is to neutralize the increased friction of the brushes against their holder caused by centrifugal force against the brushes at high speeds.

The motor is centered on the center line of the axle. An eccentric, of 7/32-in. throw, is fixed to the outer end of each shaft. An internal gear is carried by and rotates upon the field shaft eccentric. An external gear, concentric with the shaft, is keyed to the stationary housing and meshes with the internal gear which connects by means of a flexible jointed shaft to the wheel hub. It will be noted that only one of the gears is rotatable, the other one being held absolutely rigid. At the armature end the construction differs by mounting the external gear, instead of the internal one, upon the eccentric, and keying the internal one fast to the housing. From this point the construction duplicates the other end.

When the internal gear is the rotative element, as at the field shaft end, the direction of rotation remains unchanged between the motor and the wheel, but with the external gear as the rotating member, as used at the armature end, the direction is reversed. The opposing directions of the motor elements are thus rectified without recourse to intermediate gears.

Because of the large diameter of the pinion

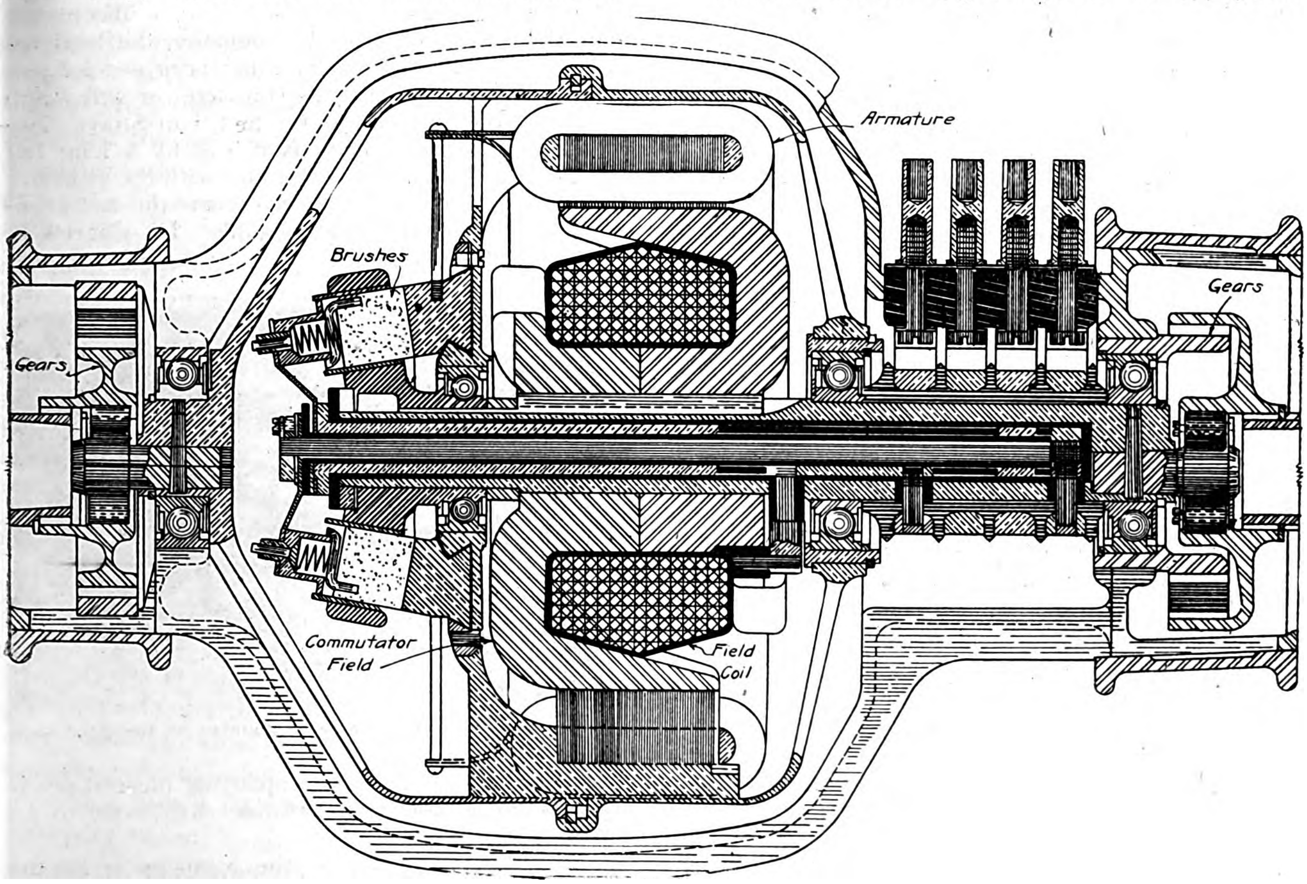


Diagram Showing Arrangement of Motor Parts and Gears.

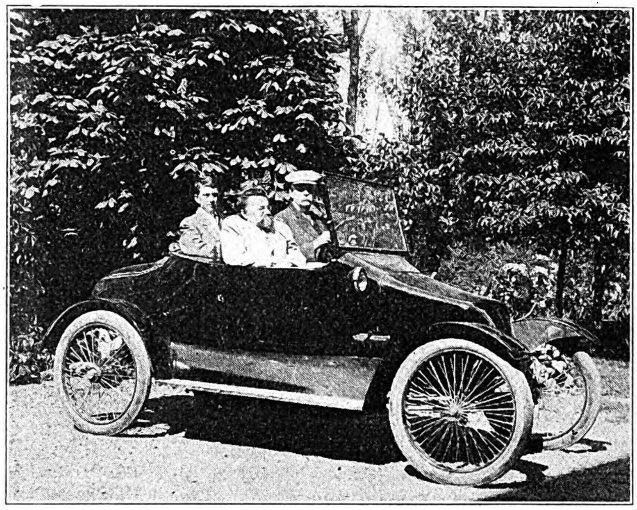
element and the consequent large arc through which the gears mesh, dividing the stresses through a large number of teeth, they are very durable. This feature also provides noiseless operation, minimum wear and high efficiency, for there is practically no rubbing action during contact to cause noise, wear and friction.



"Dey" Electric Experimental Car.

The total weight of the four gears, two on each end, is 4⅝ lbs.

The axle is made up of a steel housing for the motor and gearing at the middle section, with steel tubing extensions to the wheels. Caps covering the gears hold the power plant in position; these caps are held in place by taper rings that can be driven off in less time than would ordinarily be consumed in removing a single bolt or nut. These rings also retain a light aluminum cap that covers the unprotected side of the motor. The current is taken into the motor by means of slip rings and there is, therefore, no necessity of disconnecting wires when removing the motor.

In the latest design the control is very similar to that of a gas car with the gear shifting left out. For speed variation a foot lever is used in a manner identical with that of a clutch lever. When the foot is removed from this lever the car runs at full normal speed. A slight pressure inserts resistance, giving the effect of a slipping clutch, and as the pressure is increased, resistance is added, until the current is completely shut off. Any further movement converts the motor into an electric brake, and an extreme movement applies the mechanical brake. There is also an additional emergency brake, and as a further means of stopping the car the motor can be reversed through resistance. An accelerator pedal, acting upon the field, increases the speed to 30 or more miles per hr. Another lever providing "forward," "reverse" and "neutral" is interlocked with the speed control, to permit shifting only in high resistance or open circuit.

On down grades the motor recharges into the battery at a speed as low as 3 miles per hr. This automatically slows down the speed as the grade becomes steeper, thus making the driving unusually safe. An increase of speed may be obtained at any time, however, by means of the accelerator.

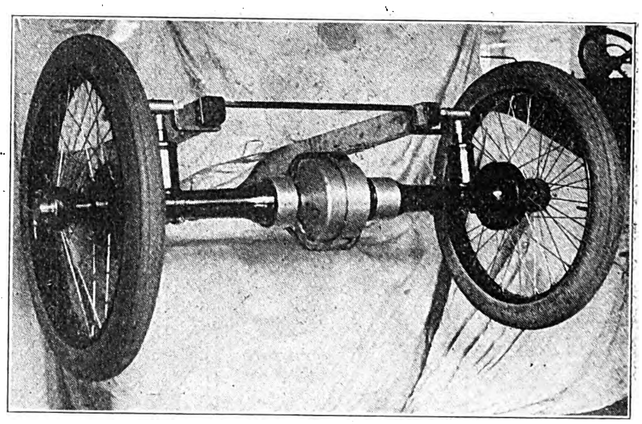
The frame of the chassis is of wood, with truss rods under the side bars. The battery is carried beneath the floor, attached to the truss rod posts. This allows the body to be used exclusively for passengers and luggage, and also avoids all troubles due to spilled electrolyte. The method of suspension is such that the battery can be readily lowered to the floor by one person and the top is accessible for adding water by lifting a trap door in the floor. This location is ideal for obtaining low power consumption and gives a very low center of gravity that conduces to a comfortable riding and safe car. The vehicle is also equipped with air springs.

In the design of this car special attention has been given to keep it as light in weight as possible without decreasing its reliability or limiting its sphere of action. As a result the battery used is also much lighter than ordinary and it is claimed will provide power in excess of 100 miles per charge. This lightweight factor also permits the car to be produced at a much lower cost.

The car is also equipped with a portable charging plant, weighing about 100 lbs., which is carried under the bonnet. It consists of a 4-cylinder, 4-cycle air-cooled engine, minus a flywheel. It is direct-connected to the ring armature of a dynamo, which acts as a flywheel, very similar in design to the motor. The field of this dynamo, however, is stationary. This gas engine can also be used to drive the car, if desirable, and when operated in this manner offers many economies over the ordinary gas automobile.

The gas-engine plant will charge the battery at any time, while the car is running or standing. An automatic switch cuts off the battery and stops the engine whenever the battery becomes fully charged. The dynamo acts as a starter when charging is desired. If the daily mileage is less than the battery capacity the plant can be removed from the car and used as a stationary charging plant for the car or for lighting or other work. It can be easily replaced in the car when necessary. The car will be manufactured both with and without the charging plant.

Up to the present time, due to the incomplete financial arrangements of the company, the final details of marketing the car have not been decided. It is expected, however, that the complete car will weigh less than 1000 lbs. and sell for less than $1000. According to present indications it will fill a long felt want in the electric vehicle line and with the auxiliary charging plant added, should overcome the last argument against this type of automobile. Dr. Charles P. Steinmetz, of the General Electric Co., Schenectady, N. Y., who in one of the accompanying illustrations is shown riding in the demonstration car, is one of its advocates.



The Small "Dey" Electric Motor Is Mounted on the Rear Axle.

The temporary office of the company is at 303 Arlington avenue, Jersey City, N. J.

Editorial Comment

Energy Production and Fuel Consumption of Public Utilities

PRODUCTION of electrical energy by public utilities for the month of March, as compiled by the United States Geological Survey, and appearing elsewhere in this issue, together with the fuel consumption, offers material for considerable thought. The data is not complete, unfortunately, because applying to only about 89% of the total generating capacity of public utility companies, but it may safely be taken as indicating the approximate production by those whose primary function is power production, and the fuel consumption involved.

A monthly energy consumption of 101,400,000 kw-hr. is deserving of special mention. A careful and reasonably close knowledge of the energy consumption for every month of the year is a true index of the industrial activity of the country. Sulphuric acid and several other basic materials have been referred to at different times as the indices of a country's commercial activity, but surely with the rapid growth of public utility supply the kilowatt-hour may come to more truly indicate the status of the country's industrial activity.

To some, the fact that 41% of the total energy generated was obtained from water power may be somewhat of a shock. The fact is that the central stations are better able to utilize water power in a big way than the individual industrial interests because the transmission line modifies geographical drawbacks and links up source of power production with the market for it. Moreover, load-factors of the utility are more favorable for making the hydroelectric development financially worth while. Of course, if a comparison of the total power produced by all producers of power were considered instead of only those producers who have done most to utilize water power, the good showing made by water power in the data referred to would be less pleasing.

Decreasing Electrical Machinery Breakdowns

BREAKDOWNS of electrical machinery do not occur nearly as frequently as in days gone by, thanks to the lessons taught by many years of experience in design, construction and operation of motor, generators and other rotating machinery. When a machine is subjected to much more violent service and abuse than it was designed to withstand it is not surprising when it gives way under the abnormal strain. When a breakdown occurs in perfectly normal service however, it is indicative of faulty design or construction, and the occurrence of failures of this kind from time to time shows that we still have much to learn or at least to put into effect to make motor and other electrical machinery service still more reliable than it is.

For this reason all the information based on experience in investigating and remedying breakdowns should prove of value in making their recurrence extremely rare. The article on this subject, published in this issue, gives such information. The author, Dr. C. W. Worral, narrates a considerable number of interesting experiences in which motor and generator failures were thoroughly investigated until the cause of the trouble was found out and removed. These cases occurred chiefly in English industrial plants and may represent some conditions not so commonly met in American practice. However, most of the lessons they teach are applicable here also.

Briefly, these lessons may be summarized as follows: Use high-grade insulation, carefully applied, and in service protect it from deleterious substances; take pains with the details of construction of cores, connections, bearings, ventilating accessories, etc.; make the construction so rugged as to eliminate metal fatigue due to vibration. These are by no means the only precautions to observe in order to improve the dependability of electrical machinery service, but at times they prove of paramount importance and are therefore worthy of serious consideration.

Why Not Built-In Electrical Appliances?

THERE is an increasing tendency to equip modern apartments and homes with built-in devices such as ice boxes, book racks, buffets and even beds. By so doing great conveniences can often be obtained in arrangement, etc.

It has long been the practice to equip laundries with built-in or stationary wash tubs, thus eliminating the need for lifting tubs and carrying water. The modern electric clothes washer is, of course, a great improvement upon old methods and in certain classes of homes its movable feature is a great convenience which offsets in a way the inconveniences attending the filling and emptying of the washer. Homes and apartments equipped with spacious laundries, however, still lack built-in electric washing machines, yet the machines, with a few minor changes, could easily be adapted to this purpose. The present washing machines can, of course, be permanently located in a laundry and a plumber employed to make desirable plumbing connections and an electrical contractor to install permanent wiring. This, of course, suggests a field that is now being overlooked by electrical contractor-dealers, namely the installation of permanent, approved types of wiring connections for permanently located washing machines.

The washing machine manufacturers, with perhaps one exception, appear to be overlooking the need for a built-in washing machine that can be installed as an integral part of a laundry just where it is wanted and with its own plumbing facilities that will permit of easy filling and emptying as well as cleaning.

Manufacturers of dish-washing machines are also overlooking the same need. A dish-washing machine is claimed by some to be as much of a bother to keep clean and operate in a family of two as is the old method of washing dishes by hand. A built-in dish washer with its own faucets and drains could be kept clean easier and would most likely meet with good demand from house owners and the higher class apartments.

Although a dish-washing machine leaves the dishes practically dry because of the hot water used, they are not always perfectly dried. This suggests the advisability of combining a stationary dish-washing machine with a dish-drying device that will eliminate hand drying of both dishes and silver entirely by the passage of a current of hot air over the dishes.

It will not be far in the future before people will be demanding built-in laundry and dish-washing machinery because of the great convenience they offer. Tenants do not desire to invest in relatively expensive apparatus for these purposes and to have them add to their moving burdens, yet practically all would most likely be willing to pay a slightly higher rent if these appliances formed an integral part of the building.

Washing-device manufacturers can well afford to give these matters their serious thought and attention.

Reach the Middle Classes First

PROMINENT department store in one of our large cities that was doing a very prosperous business decided several years ago to remodel on an extensive scale which it did at considerable expense, feeling that its more inviting and pleasing appearance would further increase trade.

When the remodeling was completed, however, its dream failed to materialize. Trade in place of increasing was rapidly declining. Old customers were sought and asked why they had ceased to trade at the store. It was found that a number of women frankly stated that they felt out of place in the store, that they did not feel well enough dressed to enter the store without a feeling of embarrassment due to the store's luxurious appearance and fittings making them feel as if they were poorly clothed and out of place in such an atmosphere. The store then realized the mistake it had made. The bulk of its trade was derived from the middle classes. It could not hope to do business with only the richer classes without sacrificing the greater part of its trade. The store was remodeled again, its luxurious fittings removed and merely an atmosphere of simple refinement without extravagance or show introduced. Trade immediately began to build up again.

This is but the experience of one store. It represents one extreme. The other extreme, too, must be considered. The person of average means feels he is out of place in a store in the slum districts of our larger cities and would feel equally as out of place if such stores were located in better districts but retained their slum atmosphere.

An electric shop to be successful must cater to those classes of people from which it can expect the most trade. This is what is largely responsible for the success of the Ford Motor Company. It realized that the number of people who could afford to buy high priced or medium priced cars were few, that the lower it could make its price, the more cars it could expect to sell and, hence, the greater its success, because of the greater number of people having modest and smaller incomes. Such people form by far the bulk of the population of the world, of our country and of practically all communities.

It is within this class that the greatest number of electrical appliances are sold. The prices of such appliances are within the reach of most pocket books. This, of course, means that the more wealthy classes are also good prospects for the sale of electrical appliances, but being relatively very few in number, a contractor-dealer or a central station cannot afford to cater to them and neglect the middle classes which are numerically much greater, and, hence, represent a better and larger market.

The electrical dealer or central station should, hence, bear this in mind in locating its store, in decorating and furnishing its interior and exterior, in selecting salespersons, in writing and designing its advertising matter, etc. One of the secrets of success in merchandising is finding where one's best and largest market exists and then going after this trade in the manner that this trade demands. The best and largest market for the sale of electrical appliances is among middle classes. It is the market that the central station or electrical dealers should consider first and which will yield the best returns with a minimum of sales effort, advertising effort and expense. The cost of reaching a large fertile market is less per person than the cost of reaching a smaller market.

Greater efforts can be made to reach the richer and poorer classes after the middle classes are being cultivated properly. Advertising and sales efforts designed to reach the middle classes will bring returns also from the richer and poorer classes, more so than advertising and sales efforts designed to reach either of these two classes, will bring results from the middle classes.

Sell the middle classes first—reap the best grain first.

Current Events

A. I. E. E. Committees and Development Report — Joint Convention — Sales Managers Meet — Convention Plans

NEW A. I. E. E. ADMINISTRATION APPOINTS COMMITTEES.

List of Chairmen and Members of Edison Medal Committee Announced.

At the first meeting of the Board of Directors of the American Institute of Electrical Engineers for the administrative year beginning on Aug. 1, 1919, held in New York, Aug. 12, President Townley appointed committees for the administrative year beginning Aug. 1, 1919.

The chairmen of the committees appointed are as follows: Finance—N. A. Carle, Newark, N. J.; Meetings and Papers—W. I. Slichter, New York; Editing—Henry H. Horris, New York; Board of Examiners—F. L. Rhodes, New York; Sections—W. A. Hall, Lynn, Mass.; Student Branches—C. Francis Harding, Lafayette, Ind.; Membership—R. W. Krass, New York; Public Policy—H. W. Buck, New York; Headquarters—N. A. Carle, Newark, N. J.; Committee on Technical Activities—Wilfred Sykes, Pittsburgh; Standards—L. T. Robinson, Schenectady, N. Y.; Power Stations—Philip Torchio, New York; Transmission and Distribution—E. B. Meyer, Newark, N. J.; Traction and Transportation—W. S. Murray, New York; Industrial and Domestic Power—A. G. Pierce, Pittsburgh; Lighting and Illumination—C. E. Clewell, Philadelphia; Economics and Electric Service—William McClellan, Philadelphia; Protective Devices, D. W. Roper, Chicago; Electrochemistry and Electrometallurgy—E. F. Northrup, Princeton, N. J.; Electrophysics—F. W. Peek, Pittsfield, Mass.; Telegraphy and Telephoney—Donald McNicol, New York; Marine—Arthur Parker, Camden, N. J.; Use of Electricity in Mines—W. A. Chandler, Uniontown, Pa.; Electrical Machinery—B. A. Behrend, Boston; Instruments and Measurements—S. G. Rhodes, New York; Iron and Steel Industry—W. F. James, Philadelphia; Educational—J. C. Parker, Ann Arbor, Mich.

In accordance with the by-laws of the Edison Medal Committee the Board confirmed the appointment by President Townley of three members of that committee for terms of five years each, namely: Edw. D. Adams, New York; H. H. Barnes, Jr., New York, and Benjamin G. Lamme, Pittsburgh; the board also elected three of its own membership as members of the Edison Medal Committee for terms of two years each, namely: Wilfred Sykes, Pittsburgh; W. A. Hall, Lynn, Mass., and G. Faccioli, Pittsfield, Mass.

ARRANGEMENTS COMPLETED FOR CONVENTION OF EDISON COMPANIES.

Program of Convention of Edison Illuminating Companies, New London, Sept. 15 to 18.

All the necessary arrangements, together with the business and entertainment programs, have been completed for the 38th annual convention of the Association of Edison Illuminating Companies. This convention will be held at the Griswold hotel, Eastern Point, New London, Conn., Sept. 15 to 18, inclusive. As this is the first convention of the association in three years it is looked forward to with considerable interest.

As in previous years, the business program has been divided into five sessions, Tuesday morning and evening, Wednesday morning and evening and Thursday morning. In addition to the reports of the various committees, four papers will be presented for consideration and discussion, two of which will be by representatives of the manufacturing interests on timely subjects. The other two subjects are of vital importance to the association at this particular time, namely: "A Symposium of Lamp Renewal Practice" and "The Labor Situation." Further, there will be two addresses by men of high standing, as follows: "Lessons of the War" and "Fuel, with Special Reference to Pulverized Coal and Coal Oil."

An elaborate entertainment program has also been arranged. The location selected for the convention offers unusual opportunities for sports and outings of all sorts and in addition a naval exhibition is planned. Golf and putting contests, archery, croquet, tennis and trap shooting are as usual a part of the program and attractive prizes have been secured for the winners. An informal banquet will be held at the close of the meeting.

For the accommodation of the western members, Godfrey H. Atkin, Electric Storage Battery Co., Marquette building, Chicago, will assist in arranging any details of transportation.

Requests for reservations should be made without delay to Herbert W. Moss, assistant secretary of the association, 39 Boylston street, Boston, Mass.

INSPECTORS' CONVENTION TO OFFER MANY ATTRACTIONS.

Visits to Turners Falls Development One of the Many Features.

Arrangements are being rapidly completed for the reconstruction convention of the National Association of Electrical Inspectors to be held in Springfield, Mass., Oct. 13 and 14. Extra efforts are being exerted to make this the most successful convention ever held by the association and a program of unusual interest is being arranged. In addition, the city of Springfield offers many attractions to convention visitors, which assures a large attendance. In order to illustrate these local attractions the association is sending out an illustrated folder showing views of Springfield and the surrounding country and describing the municipal auditorium, where the convention is to be held.

Another feature which promises to add to the interest of the convention is contained in a letter from George W. Lawrence, president of the Turners Falls

Power & Electric Co. The stations of this company and its system are objects of great interest to electrical men and in his letter Mr. Lawrence cordially invites all attendants at the convention to visit those located in the vicinity of Springfield. Representatives of the company will be in attendance at the convention, and will provide automobiles and guides to all who wish to visit this development. That such provision may be adequate those who intend to make this visit should communicate as soon as possible with Milton S. Nettleton, 98 Hobart street, New Haven, Conn., chairman of the association's entertainment committee.

POPULAR ATTENDANCE AT I. E. S. CONVENTION SOUGHT.

Public as Well as the Trade to Be Welcomed to All Sessions of Illuminating Engineering Society.

Local attendance at the 1919 convention of the Illuminating Engineering Society at Chicago Oct. 21-24 will be stimulated in several ways. The Chicago Electrical Trades Exposition which will be in progress at that time will afford one excellent means of getting convention advertising to the public. For this purpose colored posters are being prepared for exhibition at the electrical exposition calling attention to the fact that the sessions are open to the public and offering suggestions as to where programs can conveniently be obtained. These posters will be displayed in many parts of the show.

The Chicago section of the Illuminating Engineering Society will put on an active membership drive just before the convention. This too is expected to have its effect on the local attendance.

NATIONAL FOREIGN TRADE CONVENTION TO MEET IN SAN FRANCISCO.

The seventh National Foreign Trade convention will be held in San Francisco, Cal., on May 12-15, 1920. It will be the first of these important conventions to be held on the Pacific Coast, previous conventions having been held at Washington, D. C., New Orleans, St. Louis, Pittsburgh, Cincinnati and Chicago. In deciding on San Francisco for the convention city, the National Foreign Trade Council was influenced by the growing importance of the Pacific Coast in the foreign commerce of the country, and by the enthusiastic support which the Far West has given all previous foreign trade gatherings.

While the convention itself will be held in San

Unique Convention of Household Utilities Manufacturers, Jobbers and Dealers

The convention of household utilities interests briefly reported here will undoubtedly be the forerunner of many similar gatherings, as the pressing need for the interchange of ideas and experiences in this field are obvious. Commenting on the value of such conventions, C. S. Beardsley, general manager of the United Electric Co., says: "It was the most unique and successful convention I have ever had the pleasure of attending. It was unusual in that it included manufacturers, jobbers, dealers and salesmen. It gave us all some new angles on the household utility business and impressed upon all of us the magnitude to which this business has grown."

There was held in Minneapolis, Minn., Aug. 14, 15 and 16, an unique convention. It is the first time in the history of electrical trade that a convention was held of the manufacturers, jobbers, dealers and salesmen.

It was called by the Sterling Electric Co. of Minneapolis and the Kelley Hardware Co. of Duluth.

It was the original idea of Harry Bohn, general manager of the Household Utilities Department of the Sterling Electric Co.

All of the dealers and salesmen handling the Gainaday washing machine, the Ohio-Tuec vacuum cleaner, the Simplex ironing machine, the Ruud automatic water heater and the White portable sewing machine, were invited to the convention.

There were about 200 in attendance.

The salesmen were given an opportunity to present their views, the dealers their views, the jobbers their views, and the manufacturers their views.

It was a highly successful meeting.

The program was carried out as follows:

The manufacturers furnished the statistics on the magnitude of the household utility business and impressed upon the jobbers, dealers and salesmen the necessity of getting very busy and reaping the benefits of the big business which is now at hand.

Among those attending the convention was W. L. Rodgers, president of the Pittsburgh Gage & Supply Co.; J. R. Spencer, sales manager of the same company; H. G. Grosse, president of the American Ironing Machine Co.; C. S. Beardsley, general manager of The United Electric Co.; A. P. Brill, general manager of the Ruud Manufacturing Co.; W. H. Vilett, president of the Sterling Electric Co.; Harry Bohn, general manager of the Household Utilities department of the Sterling Electric Co.; W. N. Hart, general manager of the Kelley Hardware Co.; R. Hilgedick, sales manager of the Household Utilities department of the Kelley Hardware Co.; Fred P. Tosch, president of the Farmers Electro Lighting Corp.; J. P. Hanley, secretary and treasurer of the Farmers Electro Lighting Corp.; G. N. Hollway of the Mason City Electric Co.; P. D. Kline, vice-president and general manager of the Wisconsin-Minnesota Light & Power Co., together with eight managers of their various plants; Guy Bisbee, president of the Fixture Equipment Co., and others from North Dakota, South Dakota, Iowa, Wisconsin and Minnesota.

It is hoped that this will set an example to other manufacturers, jobbers and dealers to get together in these conventions for the reason that there is no doubt it will stimulate the use and sale of electric appliances of all kinds.

Francisco, it will really be a Pacific Coast gathering, and the cities of Seattle, Tacoma, Portland, and Los Angeles will share with San Francisco in the attention of the visiting delegates.

CENTRAL-STATION SALES MANAGERS HOLD INTERESTING CONVENTION.

Getting New Business, Principal Topic of Discussion at Annual Meeting at Association Island.

Over 40 central-station people, including sales managers and representatives of other commercial activities, were present at the Sales Managers' convention at Association Island, Henderson Harbor, New York, Aug. 4, 5 and 6. The program included 15 papers on pertinent and timely subjects relating to new business getting and prompted thorough, extended discussion. This was the first convention since August, 1916, and the resumption of these unique gatherings was welcomed.

A special feature of the program came in the second session, Monday evening, when W. D'A. Ryan, illuminating engineer of the General Electric Co., gave a talk illustrated with lantern slides on "Mazda Searchlights and Intensive Street Lighting with Special Reference to the Saratoga System."

The meetings were held in the new Meeting building, which has been erected by the Association Island Corporation to take the place of a tent formerly used. Acting Chairman J. F. Becker, of the United Electric Light & Power Co. of New York City, presided at the first meeting. The president's chair and table used were the gifts of the Sales Managers' convention of 1916 to the Association Island Corporation.

The program of papers was as follows:

First session, Monday, Aug. 4.—"Expense Accounts," R. S. Hale, superintendent of the Special Research department, The Edison Electric Illuminating Co. of Boston; "Merchandising Central-Station Service," John G. Learned, assistant to the vice-president, Public Service Co. of Northern Illinois, Chicago; "Motor Rules for Central-Station Lines," R. H. Tillman, manager, New Business department, Consolidated Gas, Electric Light & Power Co., Baltimore, Md.

Second session, Monday evening, Aug. 4.—"Mazda Searchlights and Intensive Street Lighting with Special Reference to the Saratoga System," W. D'A. Ryan, illuminating engineer of the General Electric Co., Schenectady, N. Y.; "The Incandescent Lamp from the Standpoint of the Manufacturer," S. E. Doane, chief engineer, National Lamp Works of General Electric Co., Cleveland, O.

Third session, Tuesday morning.—"Co-ordination of Central-Station Service with Private Plant Operation," L. R. Wallis, superintendent Sales department, The Edison Electric Illuminating Co., Boston; "Isolated Plant Costs as Influenced by the War," John W. Meyer, assistant commercial manager, Philadelphia Electric Co., Philadelphia; "Comparative Power Sales, an Index to Trade Conditions," H. H. Holding, general power representative, Public Service Electric Co. of New Jersey, Newark, N. J.; "Will Industrial Power Customers Approve Increases in Rates to Compensate for Increase in Operating Costs?" also by Mr. Holding; "Typical Report of a Large Office Building with Hydraulic Elevators," W. H. Whitton, general agent, and H. T. Luscomb, acting commercial engineer, New York Edison Co., New York.

Fourth session, Tuesday evening.—"Advertising by Central Stations—A Review and Analysis of Policies—Recommendations for Improved Practice," L. D. Gibbs, superintendent of Advertising department, The Edison Electric Illuminating Co., Boston; "Merchandising Electrical Appliances," Ernest A. Edkins, general manager of Electric Shops, Commonwealth Edison Co., Chicago; "Some Observations on the Tendency Toward Restriction of Central-Station Merchandising," G. E. Miller, sales manager, Cleveland Electric Illuminating Co., Cleveland, O.

Fifth session, Wednesday morning.—"Merchandising Incandescent Lamps," T. I. Jones, general sales agent, and G. J. Liebman, chief clerk, Sales department, Brooklyn Edison Co., Brooklyn; "Progress in Electric Melting of Non-Ferrous Metals," John D. Noyes, senior sales engineer, Detroit Edison Co., Detroit; an explanation of the work of the educational courses, conducted by the Committee of Education, Commercial Section, N. E. L. A., Fred R. Jenkins, manager, Central Station Institute, Chicago.

Sixth session, Wednesday afternoon.—"Delivery of High Tension Service to Large Consumers," Rawson Collier, operating and sales manager, Georgia Railway & Power Co., Atlanta, Ga.; Question Box discussion.

The following is a list of those present grouped under the companies represented: Cleveland Electric Illuminating Co., Cleveland, O., G. E. Miller, sales manager; Commonwealth Edison Co., Chicago, Ernest A. Edkins, general manager of Electric Shops; Oliver R. Hogue, head-lighting agent, and Fred R. Jenkins, manager, Central-Station Institute; Brooklyn Edison Co., Brooklyn, N. Y., T. I. Jones, sales manager, and G. J. Leibman, chief clerk, Sales department; Public Service Co. of Northern Illinois, Chicago, John G. Learned, assistant to the vice-president: Georgia Railway & Power Co., Atlanta, Ga., Rawson Collier, operating and sales manager; Public Service Co. of New Jersey, Newark, N. J., H. H. Holding, general power representative, and F. D. Pembleton, assistant new business agent; New York & Queens Electric Light & Power Co., New York, Charles A. Barton, general sales agent, and L. J. Montgomery, assistant general sales agent; New York Edison Co., New York., A. A. Pope, assistant general commercial manager; W. H. Whitton, general agent, wholesale; A. Hetz, statistician; Walter Neumuller, assistant to the general commercial manager; C. K. Nichols, general agent, power; H. T. Luscomb, acting commercial engineer; C. N. Lewis, heating engineer, and C. L Law, manager Bureau of Illuminating Engineering; Detroit Edison Co., Detroit, Miss S. M. Sheridan, sales manager; John D. Noyes, senior sales engineer, and Philip J. Savage, assistant to the general manager; A. H. Touscany, appliance sales, and Miss Florence Norwell; The Edison Electric Illuminating Co. of Boston, L. R. Wallis, superintendent of Sales department; R. S. Hale, superintendent of Special Research department; L. D. Gibbs, superintendent of Advertising department, and C. E. Greenwood, superintendent of Appliance department; Potomac Electric Power Co., Washington, D. C., H. A. Brooks; The United Electric Light & Power Co., New York City, J. F. Becker, sales manager; Drake V. Smith, district sales manager, A. F. Berry, commercial engineer, and S. H. Gillerup, advertising manager; Philadelphia Electric Co., Philadelphia, Joseph D. Israel, district manager; Charles J. Russell, general commercial manager, and John W. Meyer, assistant commercial manager; Consolidated Gas, Electric Light & Power Co. of Baltimore, Md., R. H. Tillman, manager New

Business department; General Electric Co., Schenectady, N. Y., W. D'A. Ryan, illuminating engineer, and H. E. Mahon; National Lamp Works of General Electric Co., Nela Park, Cleveland, S. E. Doane, chief engineer; National Electric Light Association, Commercial Section, New York City, A. Jackson Marshall, executive representative.

The officers of the convention for the ensuing year are: Chairman, T. I. Jones, sales manager, Brooklyn Edison Co., Brooklyn; Miss S. M. Sheridan, sales manager, Detroit, Edison Co., Detroit; R. H. Tillman, manager New Business Department. Consolidated Gas, Electric Light & Power Co., Baltimore, Md..

COMMITTEE ON DEVELOPMENT, A. I. E. E., PRESENTS REPORT.

Board of Directors Approves Recommendations in Principle and Suggests Further Communications Be Considered.

The report of the Committee on Development of the American Institute of Electrical Engineers which has aroused considerable interest in engineering circles was presented to the Board of Directors of the Institute at a meeting held in New York City, Aug. 12, 1919. After the presentation of the report by Calvert Townley, chairman of the committee, the following resolutions were adopted by the board:

Resolved, That the report of the Committee on Development be received, with an expression of hearty appreciation of the valuable services rendered to the Institute by the committee.

Resolved, That the recommendations in the report of the Committee on Development, dated Aug. 12, 1919, be hereby approved in principle and that the president refer the various parts of the report to qualified committees, either existing or special, the president being hereby authorized to appoint such special committees as he deems desirable, with the request that these committees formulate definite plans of procedure with estimates of expense involved, for bringing into effect such changes in present practice as the committees deem desirable; also that these committees give careful consideration to such additional communications as may be received from the membership relating to subjects with which the committees are dealing. These reports to be presented at the October meeting of the board.

Resolved, That the report of the Committee on Development, dated Aug. 12, 1919, be released for publication, with particular reference to the technical press; and that it be published in full in the next issue of the Institute *Proceedings*, with a request to membership that the report be carefully considered and that comments upon it or additional suggestions relating to Institute activities be forwarded promptly to the secretary of the Institute, so that they may be received by him prior to Oct. 1 and be promptly referred for consideration to the various committees and officers concerned with the particular activities to which the communications may relate.

Resolved further, That the Committee on Development be continued, with particular reference to the consideration of the Institute's participation in joint activities with various other engineering and technical organizations, which activities are now under consideration by the Joint Conference Committee of the development committees of several national engineering societies.

The first part of the committee's report reviews briefly, the activities of the committee, since its formation. The Committee on Development was appointed by the president, pursuant to a resolution of the board, in the latter part of 1918. At a meeting on Jan. 10, 1919, the board passed a further resolution authorizing the appointment of an Executive Committee from the membership of the Committee on Development.

This Executive Committee held a meeting on Feb. 4, 1919, and prepared a communication to its section members, dividing the subject to be considered into three major headings, namely:

1. The relation of the institute to its members.
2. The relation of the institute to other engineering organizations.
3. The relation of the institute to the public.

Under each heading a series of questions was set up designed to bring out as full a discussion as possible and to make it clear that it was the duty and privilege of the committee to consider every angle of Institute affairs. This letter in addition to being sent to each member of the Committee on Development was brought to the attention of the membership and the sections in order to encourage suggestions. At a meeting of the Executive Committee on May 8, communications had been received from 16 sections and from a number of individual members. Most of these communications showed clearly that the sections had given the matter earnest and careful study, and realized the opportunity that was being offered and were anxious each to do their part. These communications expressed such a general unanimity of opinion on many of the questions considered as to indicate very clearly the wishes of the great body of the members and incidentally to make the work of compiling the views of the different sections remarkably simple.

A summary of the views presented was prepared and a tentative plan of procedure outlined by the Executive Committee and sent to the section members of the committee on May 13th with the request for further comment and criticism. Several responses to this communication were received. The tentative plan of procedure was very generally endorsed either entirely or with minor modifications.

A third meeting of the Executive Committee was held June 16 and a report to be presented to a meeting of the full committee at the annual convention was prepared, the same being the original tentative plan as modified to meet the criticisms received.

At the Lake Placid convention the meetings of the section delegates and the Development Committee were merged. The president, the Board of Directors, several past-presidents and a few guests were present at this meeting and the entire report was very fully discussed. On the following morning the chairman presented the recommendations to an open session of the convention which adjourned until the evening of the same day and discussed the report at length. The recommendations presented are the result of these proceedings and the committee believes they express the consensus of opinion of the membership at large.

These recommendations as presented are substantially as follows.

Recommendations Affecting "Proceedings."

Concerning the *Proceedings* the committee found an almost unanimous view that it does not seem sufficiently to interest the membership at large, and the suggestions of a remedy cover a wide range of possibilities. The value of the class of papers which heretofore have been published is appreciated and it is insisted that the high standard should be maintained but it is believed that this view is not inconsistent with a recognition of the rights of 90% or perhaps 95% of the total membership who are concerned with the day to day engineering problems and with the personal side of engineering relationships. It is believed that if the *Proceedings* can be properly expanded that publication will serve better to both bind the present membership closer together and furnish an added incentive for membership. The committee devoted a great deal of time to discussions of this matter but felt that with the recommendations of the various sections and the stenographic report of the Lake Placid meetings to be considered, further study should be given to this matter. They, therefore, submitted the following recommendations, to wit:

Publication.—That the Publication Committee be asked to consider and recommend to the Board improvements in the present plan of publishing the *Proceedings* and the *Transactions* and of printing and distributing copies of institute, section and branch papers.

That in dealing with these questions the Publication Committee consider:

A. Enlarging the editorial and executive publication staff for the purpose of expanding the *Proceedings* to contain additional live matter of interest and value to the membership as a whole without giving less importance to the principal activities of the Institute, *i.e.*, the promotion of the fundamental advance in the art and the encouragement of original investigation in the field of electricity.

B. Publishing all Institute papers and occasional papers of unusual broad general interest and value from sections or from other sources; publishing a set of abstracts of every paper presented to every section so that each month there will be a complete record of this class of Institute activity.

C. Eliminating as far as may be feasible the duplication of expense now incurred by twice publishing the papers heretofore distributed (in both the *Proceedings* and the *Transactions*) but without depriving the membership of the *Transactions* in some form.

D. Publishing discussions in the *Proceedings.*

E. Endeavoring to increase the revenue producing capacity of the *Proceedings* by expanding its advertising policy and if necessary changing its page dimensions.

F. Printing pamphlet copies of some or all section and perhaps branch papers and economizing on the cost of printing Institute and such section and branch papers by limiting their quantity and free distribution while making them available for the membership.

In considering the foregoing summarized recommendations the Publication Committee was asked to examine the stenographic report of the Lake Placid sessions of the Development Committee and of the institute.

Closer Personal Contact Urged.

Another unanimous desire of the membership is for closer contact between the institute officers, prominent engineers and the sections as a means of improving the morale of the organization, stimulating section activities and of interesting the membership at large, particularly the younger members, in institute work. On account of the large number of sections and branches this is not considered practical under present conditions. An alternative is to have more officers and let them be chosen from different parts of the country. If this be done and these officers are to be participants in the management means must be provided to insure their attendance at institute and board meetings. It is believed that these objects can be accomplished by decreasing the number of institute meetings and by holding them in different parts of the country and by paying the expenses of board members when in attendance. If the institute meetings are not to be held in New York it follows that the New York members should organize a section. In order to accomplish these results, the committee made the following recommendations, namely:

Organizations.—(*a*) That a New York Section be organized and conducted on the same lines as existing sections elsewhere.

(*b*) That the present practice of holding some of the institute and directors' meetings in different localities, where local sections are established, be extended, instead of holding nearly all of these meetings in New York as at present. It may be desirable to reduce the frequency of Institute and directors' meetings and hold them every two months or perhaps even less frequently instead of every month as now.

(*c*) That the country be divided into geographical divisions corresponding in number to the number of Institute vice-presidents. If more than six divisions should be thought desirable, they should be established and the number of vice-presidents increased to correspond. In order to allow for the future shifting of membership density and at the same time to escape the necessity of cumbersome constitutional amendments, the number and delimination of geographical divisions should be specified in the by-laws instead of the constitution to provide for ready amendment by the Board of Directors.

(*d*) That one vice-president be selected from each geographical division, the president and managers to be elected from the membership at large as at present.

(*e*) That the institute should pay the traveling and living expenses of the officers and board members when attending Institute meetings.

(*f*) That it be the duty of each vice-president to visit each section in his own division at least once a year, the Institute to pay his traveling and living expenses for such visits. Of course it would also be desirable if the vice-presidents could exchange visits.

(*g*) That the vice-presidents' term of office be lengthened from one year to two years and the constitutional inhibition against the election of a vice-president as manager be removed. Provide against too extended tenure of office by a constitutional provision that except in the case of a manager or a vice-president, who may be elected president, no member may continuously hold office longer than six years.

Activities.—(*a*) That committee work be decentralized as far as it may be found feasible and desirable by substituting section committees for Institute committees. Appoint a general committee to study this question and make recommendations.

(*b*) That more high grade papers of general engineering interest be presented.

(*c*) That a committee be created in each section charged with the duty of assigning to the younger members specific participation in designated meetings by the preparation of papers, discussion or otherwise. It is hoped by this means and by the appointment of a reasonable number of the younger men to the larger committee membership caused by decentralization, that the interest of the younger men will be stimulated and their loyalty increased.

Encourage Participation in Public Affairs.

It is recognized that engineers do not participate as actively or as prominently in public affairs as they should and that both the public welfare and their own individual advancement would be promoted if this condition could be rectified. Two general reasons are believed to be responsible for this, one a lack of any general organization of engineers which would facilitate such co-operation, and second, too great technical specialization in the engineering curricula of technical schools and colleges.

The first of these reasons was very generally brought up in one form or another by the sections and although it is recognized that a corrective can be applied only by co-operation with other engineering bodies, it was felt that a constructive step would be taken by adopting a skeleton plan for co-operation and then appoint conferees to discuss the matter with other societies. With this object in mind, the committee recommended:

Local Federation.—(*a*) That a comprehensive but flexible uniform outline for the federation of local engineering bodies be prepared, taking advantage of the experience already gained by existing affiliations.

(*b*) That we use our endeavors to have the other national societies establish and support local sections along lines similar to ours but do not confine local federations to such branches, rather planning to include all the worthy engineering bodies.

(*c*) That wherever such federations can be organized there be established under an appropriate name a federated local council of engineers to be made up of a properly apportioned number of representatives from the different locals.

National Council.—(*a*) That there be established a direct touch between each local federated council and a National Engineering Council composed of delegates from as many national engineering societies as are willing and worthy to participate.

(*b*) That through the medium of the national and the local federated councils there be perfected a working arrangement for engineering co-operation in all public affairs where such is desirable.

Engineering Congress.—That there be inaugurated the custom of periodically holding an engineering congress, the delegates to which should be selected from all parts of the country under a plan to be developed for suitable representation, this congress to consider and take action on such matters of general interest to engineers and to the public as may merit its attention and as have been previously advertised, for a sufficient length of time, to permit locals everywhere to give them consideration and when possible to send instructed delegates.

The second reason, although of great importance, has not been generally considered. It was, however, the unanimous view of the members attending the convention that this matter should receive early and thorough consideration by the Institute, and the following preamble and resolution was there presented and adopted:

As the individual engineer cannot look for greater public recognition or individual advancement than his training and fitness warrant;

And, in the belief that the bigger development of the profession consists in broader social and public service by publicly-minded engineers;

Recognizing that on the one hand young engineers are employed for too long a period at work which does not stress their capabilities and, on the other, that the demands of industry for ever-increasing numbers of technicians must be supplied;

And having in mind the excellent precedents established by the medical and legal professions;

This committee would welcome the establishment at the earliest date practicable of a normal six years' collegiate course in engineering, two years of which at the least should be devoted to training in the humane arts and sciences including, for example, political science, economics, history and general letters, the last four years being devoted to sound training in the sciences and in only the fundamentals of diversified engineering.

With or prior to such a development we would endorse a program for the marked extension of vocational training in the industrial centers in order that the needs of industry may be met.

To the accomplishment of these ends this committee requests the appointment of representatives to serve on a joint committee of engineering organizations to promote such a national educational program as shall provide for the future necessities of the engineering profession consistent with the needs of society.

A motion has also been adopted that a committee be appointed to confer with the representatives of the student branches and recommend what if any changes should be made in relationship of the branches to the institute and to development in order that this very important part of institute activities should have full consideration and be given the attention which it merits.

Although the board's resolution did not specifically instruct the Development Committee to confer with similar committees from the other national engineering societies, the chairman was informally advised that where such conferences could expedite and help to crystallize the viewpoint of the several organizations concerned without committing the institute to any line of action they would be desirable. Responding, therefore, to a suggestion from the Development Committee of the American Institute of Mining and Metallurgical Engineers and to an invitation from a similar committee from the American Society of Mechanical Engineers, Messrs. Scott, Robinson and the chairman, conferred with representatives of these societies and also of the American Society of Civil Engineers, and the discussions are in progress relative to joint action by these societies. These discussions had not proceeded far enough to indicate what if any recommendations the several governing bodies may be agreed upon but the committee reported progress and stated that the spirit of co-operation was manifested by the other conferees.

STRONG FINANCIAL POSITION OF MARCONI WIRELESS TELEGRAPH CO.

The report of the directors issued in London at the end of July shows that for the year ended December, 1918, the net profit was $2,989,692, and adding to this the balance brought in from 1917 there stands to credit of profit and loss account $4,873,494. This is dealt with thus:

Dividend on preference shares 22% for the year	$ 275,000
Dividend on ordinary shares 25% for the year	$1,529,560
Put to general reserve (making it $6,250,000)	$ 750,000
Carried forward to 1919	$2,318,934

The directors stated that the above figures did not include anything in respect of its claims arising out of the war or for services rendered during the war as settlements had not been arrived at with government departments in respect of these. Since then the courts have completed the hearing of the company's claim for $35,000,000 in connection with the abandonment of the Imperial Wireless chain scheme, and have awarded between $2,500,000 and $3,000,000. The Marconi Wireless Co. holds shares in associated companies and patents which appear at the cost price in the balance sheet, *i.e.*, $6,825,547. The par value of the shares now stands at $11,729,828 exclusive of shares which have no capital denomination.

The issued capital of the company is $7,368,240 of which $1,250,000 is in preference and the balance in common stock.

RADIO STATIONS TO KEEP IN TOUCH WITH AIRPLANES.

Propose to Erect Chain of Stations Across the Continent as Aids to Aircraft.

Plans are announced by the American Flying Club for the construction of a chain of radio stations across the continent so that airplanes may be in communication with them at 30-minute intervals. The club will work in conjunction with the Government, which has already started a series of radio stations in connection with the airplane mail-delivery service.

DATES FOR IOWA STATE CONVENTION ANNOUNCED.

The date for the annual convention of the Iowa State Association of Electrical Contractors and Dealers has been set for Sept. 22 and 23. The meeting will take place in Sioux City, Iowa. F. Bernick, Jr., of Oskaloosa, Iowa, is state secretary.

Commercial Practice

Sales in Small Towns—Electric Makes 300-Mile Journey School for Salesmen Opened — Aerial Delivery of Lamps

PERCENTAGE OF SALES IN SMALL TOWNS SHOWN.

Public Service Co. Finds 95% of Sales Are Made in Larger Communities.

Some interesting facts regarding the influence of local stores are brought out in a recent article in the "Sales Bulletin" of the Public Service Co. of Northern Illinois. Out of a total of over 88,000 customers to whom the company is supplying electric service, more than 31,000, or over 35%, live in small towns in which the company does not maintain an office or store. Referring to the sales report it is found that 95% of the company's appliance sales were made in the towns in which an office is established. In other words, only 5% of the total appliance sales are made to the 31,000 or 35% of its customers living outside the towns where offices are located.

However, the amount of business in these towns is not sufficient to warrant the establishment of a store there and these figures were published to point out to the company's salesmen and its employes the opportunities that exist in these towns and to encourage them to get out after the business in the smaller communities.

The company has adopted several methods of reaching this trade, one of the most successful being its "income boosting" plan. According to this plan any of its employes in these districts may sell appliances for the company and receives a commission on the sale in addition to his regular salary. The results of this plan have been very satisfactory, not only for the company but for the employes, many of whom receive substantial checks every month for their extra efforts in this way. Another plan that has been adopted is to enclose return cards describing the appliances with the customers' bills.

LONG VACATION TRIP MADE IN ELECTRIC VEHICLE.

Recent Journey from Chicago to Cambridge, Wis., Made by Four Ladies.

The adaptability of the electric passenger vehicle for long trips was demonstrated by a 300-mile journey made in one recently. The unique feature of this trip was the fact that it was made by four ladies, alone, without any preliminary arrangements being made other than to plan where charging stops should be made. The route covered was from Chicago to Cambridge, Wis., and return, after a two weeks' vacation, via Rockford, Ill. The car was driven by Miss Jessie C. Stevens of Chicago.

The electric was equipped with a 42-cell, 11-plate battery. The following log of the journey is taken from an article in the *Round Table* of the Commonwealth Edison Co., Chicago.

FIRST DAY.

10 a. m.—Left Magnetic Motors Corporation, 25th street and Calumet avenue.

12 a. m.—Arrived Becker's garage, Highland Park, Ill. Car charged.

2 p. m.—Left Becker's garage.

3 p. m.—Arrived Colwell's garage, Waukegan, Ill. Car charged.

7 p. m.—Left Colwell's garage.

10:30 p. m.—Arrived Wilson's garage. Milwaukee. Wis. Car charged.

SECOND DAY.

11 a. m.—Left Wilson's garage.

12:15 p. m.—Arrived Waukesha, Wis.

12:45 p. m.—Car charged by Waukesha Auto Co.

3:45 p. m.—Left Waukesha Auto Co.

5:35 p. m.—Stopped at Helenville, Wis., for tea.

8:45 p. m.—Reached Cambridge garage, Cambridge, Wis., destination. Car charged.

RETURN—FIRST DAY.

9 a. m.—Left Ingleside, Wis.

12 m.—Arrived Janesville Contracting Co., Janesville, Wis. Car charged.

SECOND DAY.

7 a. m.—Left Janesville, Wis.

8:30 a. m.—Arrived Beloit, Wis. New cell put in at Beloit service station.

11:45 a. m.—Left Beloit, Wis.

12:55 p. m.—Arrived at Rockford, Ill. Car charged at Phillip's garage.

7 p. m.—Left Rockford, Ill.

9:45 p. m.—Arrived Marengo, Ill.

THIRD DAY.

7 a. m.—Left Marengo, Ill.

8:55 a. m.—Arrived Elgin, Ill. Car charged by battery service station.

7 p. m.—Left Elgin, Ill.

9:45 p. m.—Arrived Garfield Park, Chicago.

11 p. m.—Arrived 106th and Prospect avenue, Chicago, over 10 miles more power left in the battery.

The party is perfectly satisfied with the performance of the electric during the entire trip and enjoyed it even more than had a gas car been used.

SCHOOL FOR SECURITY SALESMEN.

Doherty Organization Opening Salesman's Course.

The Doherty Organization is to open a school for the training of young men as salesmen of securities. The school will be in charge of Leonhard Felix Fuld, who has had a wide experience in service instruction. He was with the United States Bureau of Education for several years and published a book for the government on education. For eleven years he had charge of the personnel for the City of New York.

The school for salesmen will probably open about the first of September. All of the details have not been worked out as yet but it is planned to offer young men desiring to enter this field of activity an opportunity to enter the school. School hours will probably be arranged so as not to conflict with regular office hours.

The opening of this school is another extension of the idea that has characterized the success of Henry L. Doherty and the Doherty Organization in the business world. The school will be well advertised and it is expected that there will be a large number of applicants for attendance. The length of the course has not been decided nor the hours that the school will be open.

AERIAL MAIL DELIVERY OF MAZDA LAMPS.

Republic Electric Co., Cleveland, Receives Order by Air from New York.

A package containing the latest development in lamp construction, the Edison white Mazda lamp, addressed to Louis Griesser, president of the Republic Electric Co., Cleveland, Ohio, was recently shipped by airplane from Belmont field, New York City. Leaving at 5:00 o'clock in the morning, it was delivered through the regular channels and in good condition at 2:00 o'clock in the afternoon.

This is understood to be the first electric lamp delivery made to a customer by Aerial Mail Service, but Mr. Ruehl, in charge of the transportation department of the Edison Lamp Works at Harrison, states that from now on aerial mail delivery service in emergencies will be a regular part of shipping service wherever the Government makes provision for such delivery.

On the present schedule, planes leaving Belmont Field, New York, at 5:00 a. m. are due to arrive in Cleveland at 9:30 a. m., connecting with planes for Indiana, Kentucky, Michigan and Ohio. Other mails will be taken to Chicago for distribution, connecting with planes for all western states, British Columbia and the northwestern territory of Canada.

When Heller field at Newark, N. J., the largest landing field in the east for Aerial Mail Service, is complete, all aerial mail will be sent direct from Newark.

Packages sent by this service are necessarily limited in size to 30 in. in length and girth.

CITIES SERVICE CO. OPENS CONSUMERS' OWNERSHIP BRANCH.

Plans Being Developed to Interest Consumers in Securities of Company and Subsidiaries.

The bond department of the Cities Service Co. of New York has opened a branch that will be devoted to the sale of securities of that company and its subsidiaries to its consumers. The work of this branch according to *Sparks,* the publication of the Toledo Railway & Light Co., one of the subsidiaries, will be handled by L. F. Wiegand of the bond department.

For some time the Doherty organization has been considering the opening of this branch, realizing the opportunities and advantages of the sale of securities to the consumers of the products of its subsidiaries. The new branch will inaugurate an active campaign along these lines, and one of its main purposes will be the development and maintenance of good will between the consumers and the public utilities.

By becoming interested financially in the public utilities from which they purchase gas, light or street car service, the consumers are in a better position to understand the problems and financial requirements of the companies in their localities. The usual difficulties encountered in the maintenance of fair relations with the public are materially lessened. Practically all the advantages of public ownership are attained through such a partnership without the sacrifice of the greater advantages of private ownership that occurs when public ownership is substituted for private ownership.

Details of the operation of the Consumers' Ownership Branch will be announced in the near future.

BRITISH MUNICIPALITY TURNS TO ELECTRIC TRUCKS.

A report recently issued by the engineer of the Hackney Borough Council is most strongly in favor of adopting the electric truck for handling the municipality's refuse.

The report summarizes in a lucid way the advantages of mechanically propelled vehicles, and as his conclusions may be helpful to other engineers, we reproduce them. They are as follows:—(1) That removal of house refuse by mechanically propelled vehicles is advantageous and more economical than horse-drawn vehicles when expedition in collection is obtainable. (2) That the conditions of working and the general arrangements of collection in the districts visited are not comparable with the conditions existing at the present time in Hackney. (3) That to secure economy by the use of mechanically propelled vehicles for house refuse collection it is essential that, as far as practicable, a continuous collection be made, and that "waiting time" be entirely avoided during the hours of working. (4) That "electric" vehicles are suitable for the work if the conditions of working warrants the use of mechanically propelled vehicles. (5) That "electric" vehicles are easy to manipulate and work and are economical in working, but more costly to purchase than other kinds of mechanically-propelled vehicles. (6) That to secure economy and efficiency by the use of mechanically propelled vehicles in Hackney, the "calling at" and the "entry" of the workmen into houses and private premises after knocking or ringing and waiting for entry must be abandoned. (7) That more frequent collections should be inaugurated and the occupiers of all premises, as is the case in all districts visited, be required to place the refuse in suitable receptacles, on the footways or in accessible situations, at times to be specified. (8) That it is expedient that a trial of the use of mechanically-propelled vehicles in this district should be undertaken by the purchase of three or four vehicles before any general scheme is adopted, such vehicles being used in different areas of the borough with a view to obtaining reliable data of cost under such improved conditions of working as can be adopted in the borough.

In Hackney at present there are thirty-four horse-drawn vehicles engaged on the work daily, and about 33,000 tons of refuse are annually collected, and the Public Health Committee believes that by an improved system of collection and the use of mechanically-propelled vehicles, a considerable saving per year can be effected.

Four trucks are to be purchased, two of 2½ and two of 3½-ton capacity.

Operating Practice

Installation of Electrically Operated Valves — Insulator Maintenance— Cable Coverings— Water Turbine Blading

COMPLETE SYSTEM OF ELECTRICALLY OPERATED STEAM VALVES.

Interesting Installation by Rochester Railway & Light Co.

The Rochester Railway & Light Co. is installing a very complete system of remote controlled steam valves in turbine and boiler room at its station No. 3. The aim of the installation is to add to the safety and flexibility of the station by enabling the important valves to be operated from a safe distance.

The original layout consisted of the proposed operation of 17 valves with the "Dean" control system. These consist of three 14-in. valves above the boilers in the old boiler house, eight boiler and two main steam line valves in the new boiler house, and four stations in the engine room, controlling steam to turbines Nos. 1, 2, 3 and 4. The steam valve on the line to turbine No. 4, while located in the new boiler house, is entirely controlled from the engine room.

To this layout for the control of 17 valves has been added recently a similar control of the Chapman valves used on boilers Nos. 12 and 21, the latest installed, and one turbine No. 5, just recently tested out and now running on the line.

All valves on lines supplying steam to the several horizontal turbines, called turbines Nos. 1, 2, 3, 4 and 5, are entirely controlled in the turbine room. These valves are in or near the upper galleries. The hold-in switches are located on the galleries near the valves, but the Dean controllers are operated from the turbine floor. Each of the turbines has an individual controller placed near the machine for close and handy operation; each has also a remote controller placed in the engine room opposite to and farthest from the machine, the steam valve of which might require emergency control. For example, on the east wall of the engine room is mounted a steel plate, on the face of which are installed the three controllers remotely operating the valves of steam lines, to turbines 1, 2 and 3. These controllers are lettered respectively Turbine 1, Turbine 2, Turbine 3, and represent in miniature the machines themselves, and the mounting plate is painted with a red band to indicate the walls and west part of engine room. In addition there is mounted on this panel—in miniature facsimile—the steam lines, with their valves, which supply steam to the turbines. The miniature valves and pipes connecting the controllers, represent the actual steam lines connecting the turbines. This system will be more fully covered later in describing the remote control panel boards for the boiler room live steam system.

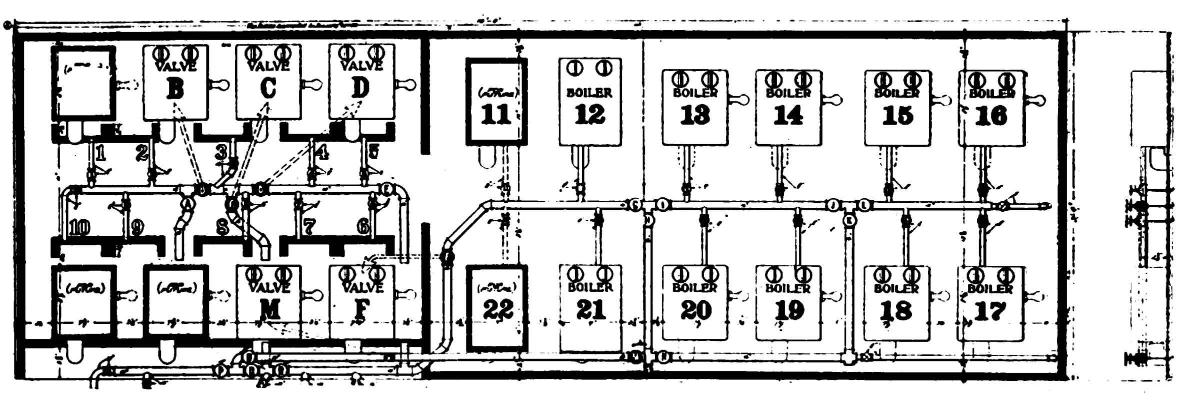
Below is a plan of the principal controller panel boards at which are operated at present 15 valves with a capacity for mounting five additional controllers. There are two similar panel boards, one located in the anteroom of Station 3 office, the other located in a steel and brick penthouse especially built for it on the north wall of the boiler house and just outside the north doorway of the boiler room. They consist of steel plates 3 ft. 4 in. high by 10 ft. long supported on steel angle legs and framework.

The face of the board, also the controllers and conduits on the board, are painted black; a red band is used to indicate the building walls; also to indicate the ten B. and W. boilers of the old boiler house. The controllers mounted in that part representing the new boiler house indicate in miniature each the exact boiler the valve of which is operated by the controller so mounted.

Ten Dean controllers represent boilers 12 to 21, inclusive. They are so marked and operate the valves of the live steam connections from these same boilers to the main steam headers supplying the turbines.

The ten B. & W. boilers of the old boiler house do not have electrical control of their individual steam valves, but five valves of the main steam headers are electrically controlled, as indicated on these panel boards and in the same manner as the boiler steam valves above mentioned. The controllers operating these valves are marked as Valve B—C—D—M—F, thus relating each controller to the valve it will operate.

In addition to the controllers representing valves or boilers, the valves of which they operate, the entire live steam piping system of the boiler room also is represented in miniature by small piping with all



Control Board Showing Layout in Miniature and Pilot Lights.

fittings, valves, etc., mounted at about one-twentieth true size. Eight-inch steam lines are represented by one-eighth inch pipe, 10 and 12-in. lines by ¼-in. pipe; 14 and 16-in. lines by ⅜-in. pipe. A small wheel disc on a stem, threaded and fitted into a tee, makes a "Dummy" valve to indicate each steam valve.

This miniature piping is true to the actual station steam pipe layout generally, except in a few places, where the details are shown more directly and in diagrammatic form. For example—all the boilers have live steam connections with large U bends—so they are represented on the panel boards as straight connections to the main steam header.

A color scheme for lettering or numbering valves, controllers and other apparatus is also being used. As each controller box is given the name and number of the boiler whose valve it operates, so the faces of the related hold-in-switch box, enclosed rheostat and fuse boxes, and face plate of the valve motor unit are each lettered with the same name and number, in white upon the black finish of the apparatus. Each valve which is electrically operated will have its key number or letter painted on the body in white upon a red ground; and the "dummy" of this valve located on the panel boards will have its wheel disc painted red with the same letter or number in white upon it.

Each valve which is not electrically operated will have its key letter or number painted on the body of the valve in white upon a black ground, and the "dummy" of it located on the panel boards will have its wheel disc painted a black ground color with the number or letter in white upon it.

The miniature valves by their color show plainly which ones are electrically operated; and the signal lamps at the top of each controller show by their color, red or green, at all times whether the valve which it operates is open or closed.

The entire system is before one like a map with its operating status indicated in detail, thus giving the operators not only a knowledge of the existing status, but also allowing the operation of any valve in any manner desired in the shortest time, under normal or emergency conditions.

METHOD OF MAINTAINING INSULATORS EMPLOYED IN GEORGIA.

Inspection Segregated from Making Repairs Improves Routine.

The Georgia Railway and Power Co. operates a very extensive system of transmission lines. Experience has proved to this company that it is far better to keep their high-potential lines in good condition than to allow them to deteriorate and then overhaul them. It is well known that insulators deteriorate with time and this company has adopted a method by which insulators can be watched and units that are becoming defective can be located and replaced before causing shutdowns and service interruptions.

The method of detecting defective insulators employed is that developed by Mr. Johnson, superintendent of transmission wires of the Georgia Railway and Power Co. This method is applicable to live lines, since it utilizes the leakage current over the defective insulators to locate the defective units. By the method employed it is possible to examine by the Johnson method the insulators on as many as 125 poles in one day and in one tour of inspection recently completed by the company 65 miles of line were inspected between June 30 and July 25.

In making these tours of inspection or search for insulators that are becoming defective the only equipment employed is the "buzz" stick used for measuring the leakage current. When an insulator is found to be defective it is painted with a daub of red paint and a report is sent in. A gang following the inspectors changes the insulators. This method has been found most satisfactory.

THREE-PART PROTECTIVE COVERING FOR CABLE SHEATHS.

Cement, Clay and Cheesecloth Recommended for Cable Covering.

Probably the best way, and always the cheapest way, to protect cables in manholes from damage from an external source is to wrap the sheath on outside of the cable with some form of covering or protective shield. In adopting a covering it is important that it serve three functions: It should radiate readily the heat which is generated within the cable; it should protect the cable from mechanical injury; it should protect the cable from heat caused by a fire in the manhole or by the burning up of adjacent cables.

The following is a good way of covering cables, and has proven most satisfactory and inexpensive in comparison to other coverings.

First, wrap the cable with a layer of cheese cloth made up in lengths of 4 in. wide. On the top of this a coating of cement and sand is plastered from ½ to ⅝ in. in thickness, and on this wrap another strip of cheese cloth. Ordinary bank sand in which there is some loam is used for the mixture, and it is mixed in 2 to 1 proportion with very little water to the consistency of very stiff mud. In winding this on with cheese cloth as above mentioned, the cloth is pulled tight, thus forcing the grout to ooze out between the meshes of the cloth, and this provides a finished outer surface for the cable. It is not considered advisable to go over this with a coating of neat cement, as this provides too fine a covering and cracks will result.

It is evident that a cement coating of this thickness will perfectly protect the cable from any mechanical injury, and it is a fact that it will protect it from a very intense heat from without.

LEAD COATING TO PROLONG LIFE OF TURBINE BLADES.

It is a matter of experience, and one which has been discussed from time to time, that if attempts are made to clean iron surfaces that are covered with lead by means of the sand blast, that the lead covering cannot be removed. It seems that the lead is forced into the depressions and interstices of the iron surface, thus becoming tightly imbedded.

Upon this fact experiments are being carried on by which it is aimed to increase the life of the blading or water turbines operating under high head with high-velocity water, as the Pelton wheel. The lead can be applied by the Schoop process, giving a smooth and uniform covering of lead to the iron surface of the blades. In this way the effect of silt and sand carried down by the water at high velocity can be made less objectionable in wearing away the surface of the turbine blades.

Contracting-Construction

Suggestions for Wiring Electric Ranges—Important Factors in Repair Business — House Wiring on Installment Plan

PROPER WIRING INSTALLATIONS FOR ELECTRIC RANGES.

Abstract of Wiring Specifications Contained in Electric Range Handbook.

With the rapidly growing demand for electric ranges the necessity of suitable and adequate wiring installations for them is becoming more important. For this reason the Society for Electric Development, Inc., has devoted a chapter of its Electric Range Handbook to the subject of wiring specifications which contains many valuable suggestions and ideas on such work. These specifications are not intended to give detailed instructions on the methods to be used but to furnish an outline of certain general arrangements and requirements which should be followed. Each job presents a different problem which must be solved bv the man on the ground and the completed job made to conform with the requirements given and the code rules.

Service wires from the outlet to the switch should be three-wire, 110-220 volts and No. 8 wire should be

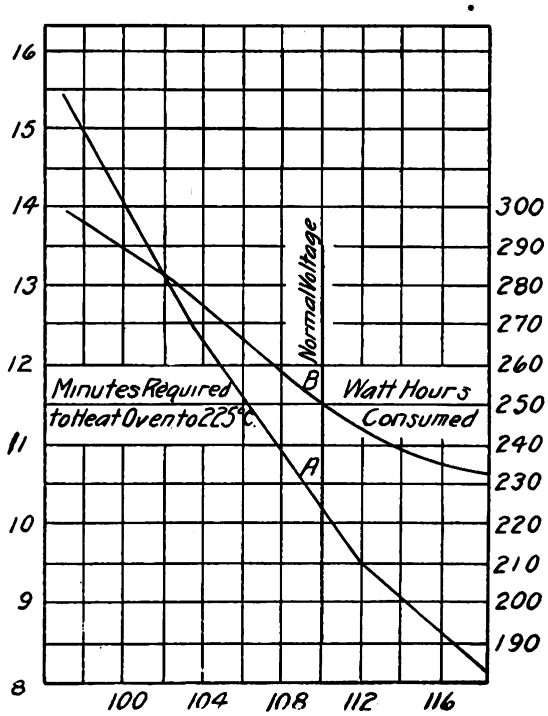


Chart Showing Importance of Maintaining Voltage in Electric Range Operation.

the minimum size used. In new buildings the exact wire size will be largely determined by the ultimate load to be installed. At present the code requires that mains feeding more than one range be large enough to supply the total load of all the ranges at one time. This ruling, however, is often modified by local authorities. However it is well to provide for the maximum requirements in the original installation rather than to change later.

In installing a range in an old residence using electric service a new meter location and switch should be installed and the present lighting mains connected to it, unless the present wiring has sufficient capacity to take care of the additional load. In apartment buildings the existing meter locations should be used if possible and a new circuit installed to the building outlet.

The service switch in a range installation should be a three-pole, single-throw, fused knife switch of 60-amp. capacity or larger. The range circuit should be three-wire No. 8 or larger depending on the size of the installation and the distance from the meter to the load. To assist in determining the proper size of wire the following table may be used:

WIRING TABLE.

TWO PER CENT DROP.

Load, watts.	Distance in feet for 110-220-volt, three-wire circuits. No. 8, 35 amp.	No. 6, 50 amp.	No. 4, 70 amp.	No. 2, 90 amp.	No. 1, 70 amp.
1,000......	375				
1,500......	250				
2,000......	185	295			
2,500......	145	235			
3,000......	125	198	316		
3,500......	105	170	270		
4,000......	93	148	236		
4,500......	83	132	213		
5,000......	76	118	188	300	
5,500......	68	108	172	273	
6,000......	62	99	158	250	312
6,500......	58	92	145	231	289
7,000......	54	85	135	215	268
7,500......	50	79	126	200	250
8,000......		74	118	187	234
9,000......		66	105	166	208
10,000......		59	95	150	187
12,000......			79	125	156
15,000......				100	125
20,000......					94

The minimum size wire, No. 8, may at first appear too large for many installations but it has been found desirable to recommend this size as it will permit installing a larger range without changing the wiring.

In addition to the service switch, a master switch, preferably of the enclosed safety type should be installed at a point within easy access of the range. Where water heaters and ranges are supplied from the same circuit this same switch must be arranged or another installed to provide for it.

The frame of the range and all conduit used should be permanently and effectively grounded in accordance with the code requirements. In addition the neutral wire of three-wire circuits should be grounded at the main switch and at the range.

It has been assumed that the range manufacturer has balanced the heating circuits connected to each leg of a three-wire range. If this is not the case the units must be reconnected of the size of wire, switches and fuses increased to amply provide for the maximum current on the more heavily loaded side.

The importance of maintaining voltage, which is largely dependent upon the wire size is shown in the accompanying chart. From this chart it can be seen that not only does it require a longer time to bring the range oven to the desired temperature when the voltage is low but the actual consumption is greater than when the proper voltage is maintained. It is evident, therefore, that the selecting of wires of a proper size is of utmost importance.

IMPORTANT FACTORS IN CONDUCT OF SUCCESSFUL REPAIR BUSINESS.

Papers at Repair and Sale of Used Apparatus Section Meeting Brought Out Interesting Discussion.

In the lively discussion that took place following the presentation of the papers at the meeting of the Repair and Sale of Used Apparatus Section of the National Association of Electrical Contractors and Dealers recently, many interesting and important factors in the conduct of a successful repair business were brought out.

In quoting prices, for example, the desirability of taking all jobs, except those on which there can be no question as to the extent of the necessary repairs, on a time and material basis was shown. It was pointed out that the average customer is concerned more in having the damaged or defective apparatus put in first class condition again than in having the particular defect that caused the breakdown remedied. To illustrate, he does not want to have a field rewound and have another breakdown occur in a few months due to a defective bearing that could and should have been replaced at the same time. As the extent of such repairs can not be ascertained without a very thorough inspection and test that it is often impossible to make until the machine is being overhauled, the cost of putting it back in good condition can not be determined until that time.

Along this line the fallacy of estimating the cost of making the necessary repairs roughly at first sight or over the telephone was also shown. Such a figure, no matter how carefully the estimator explains its inaccuracy, is always accepted by the customer as being the maximum price and if the cost of the repairs is higher he will be dissatisfied. On the other hand, if the estimate is too high it will tend to scare the customer into the purchase of a new machine.

The advisability of conducting a department for repairing autostarters, ignition systems and other electrical equipment used on automobiles in conjunction with the regular repair business was also fully discussed. The consensus of opinion among those present seemed to be that such a department could be profitably conducted if the volume of business was sufficient. However, such work can be properly done only by specialists in that line and these men are seldom capable of doing regular repair work in the shop. For this reason the volume of auto repair work handled must be enough to employ all their time or a large portion of their unoccupied time will be lost.

Handling presents another important problem, especially with the larger machines and apparatus. Very often the cost of getting such machines to the repair shop and back in place at the customer's premises again is much higher than the cost of doing the actual repair work on them. It is evident, therefore, that the relation of the cost of a job to the handling cost varies in practically every job and should be figured separately in billing.

In order to prevent complications when there is more than one job from the same customer in the shop at the same time, many of those present give every piece of work a shop or job number by which it is identified in the shop. This method also assists the office force in keeping its records of the various jobs.

Another important item is in keeping the time on jobs correctly. This is especially important in a repair shop inasmuch as nearly all the work is done on a time and material basis. If the keeping of labor records is left entirely to the workmen, discrepancies are sure to creep in which will penalize one job and make the charges on another too small. The majority of companies overcome this difficulty by using a time clock on which the men register the time when they start and leave any job.

The proportionate labor charges for work done in the shop and on the customer's premises was also discussed. Due to the fact that work done on the customer's premises presents difficulties and inconveniences not encountered in the shop and as such work is usually of the emergency order, the majority of the members were of the opinion that it should be charged for at a higher rate than work done in the shop. In addition to this higher rate the time required for getting to the work and back and transportation expenses should also be charged.

GOODWIN ENCOURAGES PART-PAYMENT PLAN FOR HOUSE WIRING.

Would Prefer House Wiring on Installment Plan to Appliance Sales That Basis.

Many electrical contractors do not care to do old house wiring on the installment or part-payment plan because there is no immediate method of collecting should the customer fail to pay. In the case of removable articles, such as appliances, the dealer can of course take them back, but with wiring such a recourse is impractical. Of course a mechanic's lien can be placed on the building which will interfere with its sale or further mortgaging, but this does not effect an early settlement.

With house wiring on this plan, however, there is an added moral factor that adds greatly to its reliability. It is on account of the existence of this factor that W. L. Goodwin, author of the "Goodwin" plan stated at the recent meeting of the Association of Municipal Electrical Engineers that he would prefer to take this business on installments rather than appliances. His statement in this respect as reported in the *Bulletin* of the Ontario Hydroelectric Power Commission is as follows:

"Of the choice between the selling of appliances on installments and house-wiring on installments, so far as security is concerned, I will take the house-wiring. We know from the experience of over 20 years, in every line of endeavor, that the credit losses on installment sales are less than 1%. As a matter of fact, they average one-quarter of 1% in the case of all the big installment houses throughout the United States. You are selling to what might be regarded as the most unreliable kind of purchaser, the one that has to buy on the installment plan, but there is something about the people of this continent that makes them keep their installment payments as faithfully as they will keep their religion. If you give a man a washing-machine on 60 days' credit, he will beat you right and left, and if you sell it on the installment plan you will have to chase him all over the country. In the case of house-wiring, however, he cannot move it away and it becomes a lien on the building."

New Appliances

Pipe Fittings with Composition Bushings — New Development in Electric Washers — Attractive Lighting Fixture

Adapti Line of Pipe Fittings With Composition Bushings.

A new line of pipe and fittings and composition bushings is being placed on the market by the Adapti Co., Cleveland, Ohio, makers of the "Adapti" line of outlet boxes and similar fittings. These fittings are especially intended for use in protecting the wires in conduit systems where they enter cutout, service and panel boxes. Being of composition, the bushings offer great mechanical and dielectric strength and involve no danger of breakage, as is the case with those made of porcelain.

They are made in all standard sizes, with a standard pipe thread that screws into the fitting itself. They can, therefore, be securely fastened in knockout holes with standard conduit locknuts and are also adaptable for use with standard couplings.

Surf Electric Washing Machine.

Recognizing that the real cleansing action in washing clothes is obtained through thorough agitation of the clothes with soapy water and that rubbing adds nothing to the real cleansing action, a new type washing machine has been developed in which all friction has been disposed with and the foregoing principle applied exclusively. It is known as the "Surf" electric washer and is made by the Surf Manufacturing Co., 518 Grand Ave., Milwaukee, Wis. As shown in the accompanying illustration, this machine operates on the oscillating cylinder principle, but makes use of a new development in this line. In the lower portion of the cylinder is placed a screened, raised bottom plate, the end portions of which are closely perforated, as can be partly seen in the illustration. The cylinder itself has no ribs nor projects to break the flow of the water. Below the bottom plate referred to, there is room for about a pail and a quarter of hot water. The clothes are thrown in on this bottom, the cover closed tightly and tub placed into oscillation. This action causes the tub to tip the clothes back and forth into this water. The water pours through the screened plate and through and over the clothes. The rising of the tub on that side lifts the clothes but drops them again in the next moment, thus meeting a rush of water coming from underneath and thoroughly showering the batch of clothes. It is from this surf-like action of the water that the machine gets its name. The water is forced through the clothes 72 times a minute, thus giving specially thorough mingling of the soapy water with the clothes.

With the exception of parts of the wringer, all of the machine is made of metal, the tub being either of galvanized iron or copper. The machine is made in one size only, having a capacity of 8 sheets, or their equivalent. It has a 12-inch reversible and removable swinging wringer provided with a safety release. All of the driving mechanism is inclosed in an oil-tight case. The drive from the motor is direct through suitable gears and shafts, a safety clutch being placed in the motor shafts to prevent burning out of the motor in case there should be any clogging in the machine. There is no opportunity for the operator to be injured in any moving exposed parts since these are all inclosed or guarded. The framework is of substantial angle iron well braced and is mounted on roller bearing castings. The machine is very simple, both in construction and operation, and is almost noiseless. It is easily controlled by means of a conveniently placed handle which covers the cylinder and another handle for controlling the wringer. A switch starts and stops the motor.

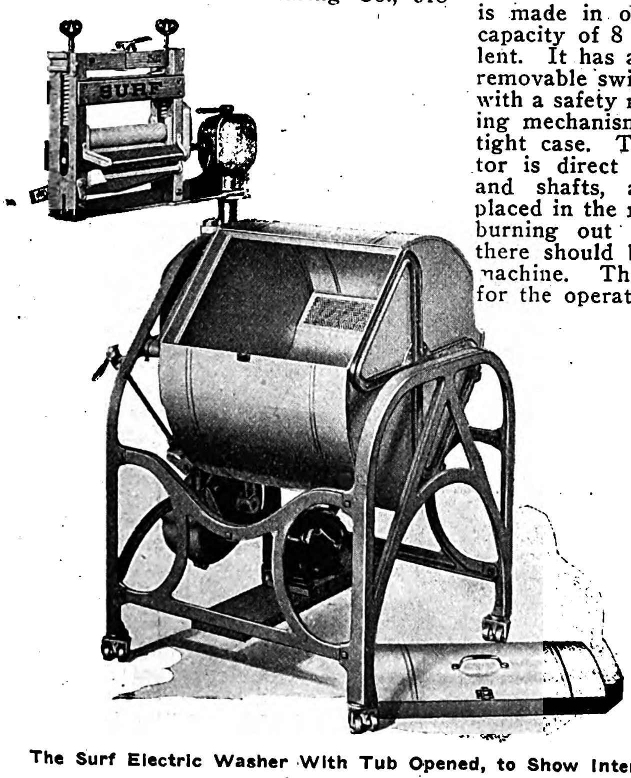
The New E-lite Lighting Fixture.

A new fixture called the E-lite has been produced after careful and exhaustive tests by the Luminous Unit Co., 2615 Washington avenue, St. Louis, Mo. This unit, in the opinion of the company, is destined to become the most popular of all fixtures for home, school and other such places.

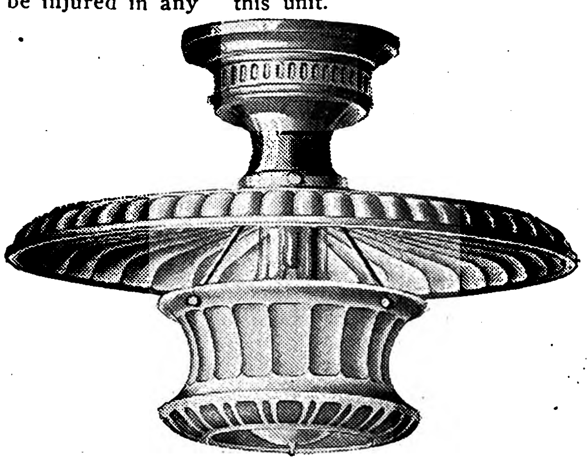
The fixture consists of a metal canopy, a white glass reflector 13 in. in diameter, and a white glass or Adam embossed etched cylinder of 6-in. diameter. Contrary to the usual design of such fixtures the lamp is encircled by the cylindrical shade but is exposed at the bottom, thus providing a certain amount of direct illumination. This feature also prevents dust from collecting in the shade and makes it easier to clean.

The unit is aesthetic, utilitarian and attractive—yet economical. It produces a soft tonal illumination and obtains maximum results from the Mazda type-C bulb which is used, and its reflector working in conjunction with the bowl produces an excellent ray distribution and eliminates shadows. It is furnished in both ceiling and chain design in three sizes for use with 75, 100 or 150-watt lamps.

The name E-lite is also significant and was adopted for two reasons; the word itself, E-lite meaning to describe the high quality of the fixture, and the "E" standing for the efficiency of this unit.



The Surf Electric Washer With Tub Opened, to Show Interior Construction.



E-lite Lighting Unit Especially Adapted for Home, School and Similar Uses.

Trade Activities

Belden Co. Erects New Building — Chicago Pneumatic Tool to Remove Headquarters to New York — Literature

The Babcock & Wilcox Co., with main offices at 85 Liberty street, New York City, has removed its Seattle office from the Mutual Life building to Rooms 1914-1917 L. C. Smith building.

Acme Wire Co., New Haven, Conn., announces that due to the increasing volume of its business in the Middle West and the desirability of keeping in closer and more frequent touch with the requirements of its customers it has opened an office in Cleveland, Ohio. Its sales representative is J. T. Crippen, the office address is 521 Guardian building, and the telephone number is Main 2024. The step taken by the Acme company will undoubtedly result in a closer and more effective association with its many friends in the Middle West.

Quigley Furnace Specialties Co., 26 Cortlandt street, New York, has been awarded the contract for the complete equipment for preparing, distributing and burning the fuel to be installed in the Falcon Steel Co.'s new sheet mill at Niles, O. This mill will use powdered coal throughout for firing boilers and furnaces and the power-plant boilers will be powdered-coal fired, using the Quigley compressed-air system for transporting and burning the coal. The pulverized coal will be transported from the milling plant through standard four-inch diameter wrought pipes to furnaces and boilers for various distances, aggregating 800 ft., and will be switched from the main distribution line to a storage bin in the power house for use as required for the boilers.

Crystal Washing Machine Co., Detroit, Mich., is distributing a "Special Merchandising Plan Book" to the trade which explains the assistance offered by this company to its dealers in promoting the sale of Crystal electric washers. This, accordng to indications, will be a particularly fruitful field for the sale of this labor-saving device and for that reason such sales helps as are described in this book should prove especially valuable to the contractor-dealer or central station. The sales helps described are all furnished by the company and consist of striking window displays, newspaper advertisments, in either matrix or electrotype form, demonstration book for the house-to-house salesman, window cards, moving picture slides, complete instructions on the preparation and maintenance of a mailing list, together with two sales letters and an outline of direct-by-mail campaign, and literature for distribution to prospective customers. This plan thoroughly analyzes the field and makes use of every known advertising strategy in leading prospective customers to the dealer's store.

Black & Decker Mfg. Co., Baltimore, has issued a catalog giving a full and illustrated description of electric air compressors, portable electric drills and electric valve grinders. A copy of the catalog will be mailed free upon application.

Youngstown Sheet & Tube Co., Youngstown, Ohio, has commenced the publication of a house organ, the initial number being dated August 15. It is a plant paper of a rather unique type, and its purpose is to promote friendliness, acquaintance and a fellow feeling among the employes of the company. So far as practicable, it will be the work of its own people exclusively. All of the matter including the art work in the first issue was done by men in its works.

Chicago Pneumatic Tool Co. is planning for the removal of its general offices from Chicago to New York. An office building is being erected at 6-8 East 44th street, New York, and it is expected that the building will be ready for occupancy early in 1920, at which time the transfer will be effected. The structure, which is being built by Westinghouse-Church-Kerr Co., is of combination steel, brick and limestone, and will comprise initially ten stories, all to be occupied by the company. The ground floor is to be an attractively designed permanent exhibition room and will contain a display of the many Chicago Pneumatic products, including Boyer pneumatic hammers, Little Giant pneumatic and electric tools, rock and coal drills, air compressors, etc. In conjunction, a completely equipped service station will be maintained. The company maintains six American plants and 26 sales and service branches, the operation of which will be more economically directed from New York. A sales and service organization more extensive than at present will be continued in Chicago.

Dantzig, Pfeiffer & Ritt announce their organization as a firm of consulting mathematicians, with offices located at 500 West 116th street, New York City. This firm undertakes to handle all problems arising in industry for the solution of which the knowledge of a mathematical specialist may be necessary. Each of the members of the firm has been privately engaged for some time in work of this nature, in addition to his other professional activities, and it was at the suggestion of clients that the decision was made to set up a consulting service which would extend to the industrial world the resources of modern pure and applied mathematics. Dr. Dantzig is a graduate of the University of Paris of the Ecole Superieure d'Aeronautique et de Construction Mecanique. He has taught at Indiana University and at Columbia. During the war he was in charge of the mathematical work of the instrument section of the U. S. Ordnance. Dr. Pfeiffer received the degree of Mechanical Engineer from the Stevens Institute of Technology and the degree of Doctor of Philosophy from Columbia University. He has taught mathematics at Harvard, Princeton and Columbia. He is an associate editor of the Annals of Mathematics. Dr. Ritt took the degree of Ph.D. at Columbia University. He was for three years at the Naval Observatory and has since taught mathematics at Columbia. During the war he was one of the chief ballisticians in the U. S. Ordnance.

Belden Manufacturing Co., Chicago, is erecting a new four-story building to be designated building No. 8. This building will correspond to the present structures in that it will be of absolute fireproof construction, no wood whatever being used. Each floor contains about 10,000 sq. ft. of clear space. The first floor is to be used for a shipping, receiving and stock room until the permanent structure to house these departments is built. The second floor will be devoted to the excess needs of several of the departments. The third floor will be used entirely for the manufacture of textile magnet wire, while the fourth floor will be given over to the manufacture of "Beldenamel" magnet wire, being so designed that the entire process can be conducted on one floor. A spur track from the belt line railway adjoining the tract of land will be built facing these buildings on the street side, but even with the second story. This will permit loading and unloading by a special conveying system designed to eliminate so far as possible handling of goods. The space in the present factory building now occupied by the magnet wire and enameled wire departments will be used for expansion of the rubber-covered wire and cord departments, which have grown rapidly in the past few years.

New Buildings of Belden Manufacturing Co.

Current News

Weekly Record of Construction Activities—Conventions

EASTERN STATES.

Lynn, Mass.—Davis Storage Battery Manufacturing Co., Chestnut street, is considering plans for the erection of a new addition to its plant. The structure is estimated to cost about $150,000.

Providence, R. I.—Ground has recently been broken by the Atlantic Mills, Equitable building, Boston, Mass., for the construction of a new three-story turbine building at its local plant on Manton avenue. The structure will be about 46x98 ft., and is estimated to cost $20,000. O. D. Purington & Co., Industrial Trust building, Providence, is the contractor.

Brooklyn, N. Y.—Plans have been filed by the R. H. Comey Co., 73 19th street, for alterations and improvements in the boiler plant at its works, to facilitate operations. Contract for the work has been awarded to Gibbons & Co., 316 Columbus street, Brooklyn.

Mt. Morris, N. Y. — Mt. Morris Illuminating Co. is making rapid progress in the construction of a power plant on the north side of the Genesee river, and it is expected that the work will be completed at an early date.

Newburgh, N. Y.—Alberger Pump & Condenser Co., 140 Cedar street, New York, has awarded a contract to the J. W. Cowper Co., Fidelity building, Buffalo, for the construction of a new addition to its local plant, to provide for increased capacity.

New York, N. Y.—Following the approval of a bond issue for $30,000,000 for various city improvements, the Board of Estimate has arranged plans for the construction of a new power plant and boiler house at the institution to cost about $200,000.

New York, N. Y.—In connection with the construction of a large new six-story cold storage plant at 780 First avenue, by the United Dressed Beef Co., considerable electrical equipment and refrigerating apparatus will be required. The structure is estimated to cost $250,000.

New York, N. Y.—Third Avenue Railway Co., 2396 Third avenue, has had plans prepared for improvements and alterations in its one-story shop building at 251 East 133rd street, to facilitate operations. Estimated cost about $6000.

New York, N. Y.—Lion Electrical Appliance Co., Inc., has filed notice with the Secretary of State of an increase in its capital from $25,000 to $100,000, to provide for general business expansion.

New York, N. Y.—Electric Bond & Share Co., 71 Broadway, has recently broken ground for the construction of a one-story extension to its power oil plant at Third and Kelley streets, Wichita, Kans., about 48x100 ft., to provide for increased operations.

New York, N. Y.—Announcement has been made that negotiations have been completed by the New York Edison Co. for the acquirement of the East Broad-Top Railroad, together with the coal mines and lands formerly owned by the Rockhill Iron & Coal Co. The entire property, which was secured for a consideration of about $5,250,000, is located in Huntingdon and Bedford counties and was purchased in order that the lack of coal should not interfere with the operation of the various plants of the company.

New York, N. Y.—Contract has recently been awarded to the New York Edison Co. for electric service for the operation of the new studio and laboratory building of the Fox Film Corp., 10th avenue and 55th street. Included in the structure are 12 complete theaters with entire electrical accessories, a large room in which a hundred sets may be erected and twenty companies work at one time, restaurant, executive and business offices, gymnasium, fire department, etc., requiring four service lines from the street to carry current for light and power, comprising two lines of 5000 amperes capacity and one of 4000 amperes for lighting, the fourth being a power connection of 400 kw. The total requirements aggregate 2800 hp. available 24 hours daily.

Oswego, N. Y.— Peoples Gas & Electric Co. has filed notice with the Public Service Commission of an increase in its capitalization from $1,000,000 to $1,300,000, to provide for general business expansion.

Watertown, N. Y.—Northern New York Utilities Co., 56 Public Square, has awarded final contracts for the construction of the proposed power plant and dam, with canal development on the Black River, Watertown. The project is estimated to cost about $250,000. The Walsh Construction Co., Watertown, is the contractor for the erection of the power plant, while Burns Brothers & Haley, Bank building, will be in charge of dam and canal work.

Bordentown, N. J. — Fire recently destroyed the engine plant and a portion of the works of the Independent Brick Co. Plant No. 2, near Fieldsboro, with total loss estimated at about $10,000. It is understood that the company is considering plans for rebuilding.

Camden, N. J.—Fire recently destroyed considerable rolling stock and a portion of the terminal of the Public Service Railway Co., Newton avenue, near Haddon avenue, with total loss estimated in excess of $250,000.

Gloucester City, N. J.—City Council is arranging plans for the installation of a large quantity of new equipment at the municipal water works, to increase the present capacity, an appropriation of $45,000 recently having been approved, to cover the cost of the work. It is understood that a like sum will be expended at a later date on further improvements at the plant.

Harrison, N. J.—Driver-Harris Co., Middlesex street, manufacturer of electric wires, cables, etc., is having plans prepared for the construction of a new three-story reinforced concrete addition to its plant, about 50x100 ft. The structure is estimated to cost $50,000.

Irvington, N. J. — In connection with the construction of a new two-story plant at 167-77 Coit street, by the Yocum Chemical Co., plans have been arranged for the erection of a boiler plant for general factory operation.

Newark, N. J.—Luthy Storage Battery Co., 420 Ogden street, has filed notice with the Secretary of State of an increase in its capital from $700,000 to $750,000 to provide for proposed expansion. The company has had plans prepared for the erection of a new extension to its plant.

Newark, N. J.—Washington Electrical Supply Co., 219 Washington street, has filed notice of organization to deal in electrical supplies. C. Katz, 115 16th avenue, heads the company.

Newark, N. J.—United Electrical Specialty Co. has filed notice of organization to operate at 207 Market street for the production of electrical supplies. William J. Bowen, 2 Broad street, heads the company.

Newark, N. J.—Plans have been completed by Stengel & Rothschild, Main street, for alterations and improvements in the boiler plant at their works, to facilitate operations. Estimated cost, $12,000.

Trenton, N. J. — City Commission has approved plans for the installation of new pumping machinery and equipment at the city water works plant, estimated to cost about $150,000. E. E. Brownell, Philadelphia, Pa., is consulting engineer for the commission.

Trenton, N. J.—Trenton Electric & Conduit Co., Tyler street, is planning for the construction of a two-story addition to its plant to cost about $10,000.

Trenton, N. J.—City Commission

is considering plans for the installation of a new ornamental arc lighting system along Sanhican Creek, from Calhoun street to the Log Basin, being an extension to the local park electric lighting system. Commissioner George W. Page will be in charge of the work.

Aspinwall, Pa.—Mackintosh-Hemphill Co., Pittsburgh, Pa., manufacturer of electrical appliances, has recently completed negotiations for the purchase of property at Aspinwall comprising about 26 acres, as a site for the construction of a new plant.

Cheswick, Pa.—The contracts for the new power plant of the Duquesne Light Co. have been awarded to Dwight P. Robinson & Co. Address A. W. Thompson, president of the company.

Dinsmore, Pa. — Breensburgh & Connellsville Coal & Coke Co. is having plans prepared for the erection of a new one-story power plant and coal tipple at its properties, to cost about $100,000. Baton & Elliott, National Bank building, Pittsburgh, are mining engineers for the company.

Grove City, Pa.—City is having preliminary plans prepared for the construction of a new addition to the municipal electric light plant to provide for increased operations. The structure is estimated to cost about $50,000. Sidney B. Martin, Penn building, Pittsburgh, is engineer.

Harrisburg, Pa. — Bethlehem Steel Co. has ordered a 5000-hp. electric plant built for its blooming mills at the Steelton plant.

Harrisburg, Pa.—Notice has been filed with the Public Service Commission by the Penn Central Light & Power Co. and the Northern Cambria Light, Heat & Power Co. of the addition of a coal clause to the schedules of rates for service.

Hershey, Pa. — Announcement has been made by the Hershey Chocolate Co. that plans are being arranged for the complete electrification of the company's private railroad, in connection with other extensive improvements and additions, estimated to cost in excess of $5,000,000.

Lewiston, Pa.—Considerable electrical and mechanical equipment will be required by the City Council in connection with the construction of the proposed disposal plant to cost about $60,000.

Philadelphia, Pa.—Connery & Co., Inc., Second and Luzerne streets, manufacturer of boilers, etc., has arranged for the construction of a new one-story brick addition to its assembling shop, about 75x90 ft.

Philadelphia, Pa.—Board of Managers of the Lankenau Hospital, Corinthian and Girard avenues, has awarded a contract to the A. Raymond Raff Construction Co., 1635 West Thompson street, for the construction of a new one-story brick transformer building at the institution.

Pittsburgh, Pa.—Fire recently damaged the plant of the Miller-Owen Electric Co., Lexington avenue and Thomas boulevard, to the extent of approximately $50,000. A quantity of electrical machinery, including dynamos and motors, was destroyed by the fire.

DATES AHEAD.

Michigan Section, N. E. L. A. Annual convention, Ottawa Beach, Mich., Aug. 26-28. Headquarters, Hotel Ottawa. Secretary - treasurer, Herbert Silvester, Monroe, Mich.

Pennsylvania Electric Association. Annual convention, Bedford Springs, Pa., Sept. 3-6. Secretary, H. M. Stine, 211 Locust street, Harrisburg.

Washington State Association of Electrical Contractors and Dealers. Annual convention, Seattle, Sept. 11. Secretary, Forrest E. Smith, 205 Boston Block, Seattle.

Southeastern Section, N. E. L. A. Annual convention, Asheville, N. C., Sept. 17-19. Secretary-treasurer, T. W. Peters, Columbus, Ga.

New England Section, N. E. L. A. Annual convention, New London, Conn., Sept. 22-24. Headquarters, Hotel Griswold. Secretary, Miss O. A. Bursiel, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Annual convention, St. Louis, Mo., Sept. 22-26. Secretary, John F. Kelly, Empire building, Pittsburgh, Pa.

American Electrochemical Society. Fall meeting, Chicago, Sept. 23-26. Headquarters, Congress Hotel. Secretary, Prof. Joseph W. Richards, Lehigh University, Bethlehem, Pa.

International Association of Municipal Electricians. Annual convention, Chicago, Sept. 23-26. Secretary, Clarence R. George, Houston, Tex.

National Association of Electrical Inspectors. Annual meeting, Springfield, Mass., Oct. 13 and 14. Secretary, W. L. Smith, Concord, Mass.

Illuminating Engineering Society. Annual convention, Chicago, Ill., Oct. 20-23. General secretary, Clarence L. Law, 29 West 39th street, New York City.

Pittsburgh, Pa.—Negotiations have been completed by the Westinghouse Home Co. for the acquirement from the Westinghouse Airbrake Co., nine tracts of land in Wilmerding, including a number of new brick dwellings, for a consideration of about $1,000,000. It is understood that the property will be utilized by the company for the construction of new dwellings for the service of employes connected with the Westinghouse interests.

Waynesboro, Pa.—City Council is considering plans for the construction of a new electric light plant for municipal service.

Baltimore, Md.—In connection with the proposed waterfront improvements planned by prominent local interests, estimated to cost in excess of $5,000,000, arrangements have been made for the construction of a new power plant to cost in the neighborhood of about $86,000.

Seat Pleasant, Md.—Plans are under consideration by the City Council for the construction of a new electric light plant for municipal service.

Warren, Md. — Warren Manufacturing Co. has had plans prepared for the installation of new power and boiler equipment to cost about $35,000 in connection with the proposed additions and improvements to its plant, estimated to cost about $250,000.

Wheeling, W. Va. — Gee Electric Co. is installing the electrical work for a big coal-stripping operation about to be started by the R. L. Culbertson Coal Co. near Cadiz, Ohio. The electrical work represents one of the largest electrical installation contracts of its kind in this section of the country. It includes motors aggregating 150 hp., electrically operated apparatus for cleaning coal and a complete lighting system for night operations.

Charleston, S. C.—Bureau of Yards and Docks, Navy Department, is considering plans for the installation of new mechanical stoker equipment and turbogenerator at the local Government station. The work is estimated to cost about $50,000.

Summerville, S. C. — Summerville Public Service Co., recently incorporated with a capital of $25,000, has acquired the local electric light and ice plant, and is understood to be considering improvements and alterations for increased service. M. Barshay is president.

Columbus, Ga. — Georgia-Alabama Power Co. is planning for the inauguration of activities on the proposed water power development near Albany, Ga., to include the construction of power plant, dam, and transmission system at Porter Shoals on the Flint river, near Albany. It is proposed to have a capacity of 15,000 hp. The project is estimated to cost in excess of $1,000,000. Baxter Shemwell, Lexington, N. C., is president of the company.

Locust Grove, Ga.—Plans are under consideration by A. R. Scott, McDonough, La., for the establishment of a local electric plant for supplying electric energy to Locust Grove and Stockbridge.

Springfield, Ga.—Citizens in mass meeting requested city officials to order election upon issuance of $10,000 of bonds for establishing light system. And building water works system.. Address mayor.

NORTH CENTRAL STATES.

Cleveland, Ohio. — Martin Bariss Co. will erect a $100,000 sawmill and power house. The specifications include electrical equipment. Architect George S. Reder, Century building, has prepared plans.

Anderson, Ind. — Anderson Foundry & Machine Co. has announced that it will enlarge its capacity with additional buildings and equipment to cost $100,000.

Connersville, Ind.—Teetor-Hartley Motor Corp., owned principally by Connersville capital, but located in Hagerstown, Ind., will soon begin the erection of a steel and concrete building, 100x1500 ft. The Ansted Engineering Co. will build a similar structure 100x400 ft. The Lexington Motor Co., to which the Ansted Engineering Co. is largely accessory, will build a new stockroom and expand its heating system.

Fort Wayne, Ind. — General Electric Co. has made two large purchases of ground within the last two weeks. One purchase was for $24,000 and the other was for $40,000. The sites acquired will be used for future extensions of the Fort Wayne plant.

Indianapolis, Ind. — Irvin Robbins

Co. will build a two-story brick and steel building, 60x400 ft., to cost $100,000.

Muncie, Ind.—Indiana General Service Co., according to a ruling of the Indiana Public Service Commission, must furnish electricity to the Muncie public library and other public buildings at a rate 25% lower than that charged consumers. The lower rate is provided for in the surrendered franchise of the company.

Chicago, Ill.—Wilson-Jones Loose Leaf Co. has purchased a site for erecting a modern factory estimated at $400,000. The specifications include a power house. Address general manager, 3021 Carroll avenue.

Deer Creek, Ill.—A company has been formed here to supply light and power to Deer Creek, Cruger and adjacent territory. J. A. Danforth is the president and F. L. Belsley, secretary-treasurer. Power will be furnished by the Peoria Light & Power Co., this company to put in a reducing station at Cruger at which point the new organization will attach on their lines. The new company has been capitalized at $25,000.

Dundee, Ill. — Packard Electric Co. will open one of its branch stores in Dundee, Sept. 1.

Elgin, Ill.—Plans and specifications for the new municipal light and power plant, for which a bond issue, is soon to be voted by the people, are being prepared in the Elgin city hall. The new plant will cost approximately $200,000.

Knoxville, Ill.—F. M. Willard and Leo Allen have formed the Knoxville Electric Co. to deal in general electrical merchandise and will make a specialty of overhauling motors and generators.

Monmouth, Ill.—Altenberg Tire & Equipment Co. will remove its factory frcm Davenport, Iowa, to this city. The company plans the erection of a four-story building to cost $100,000.

Ottawa, Ill. — Wilson & Co. have secured the contract for wiring the new high school at Marseilles for $496.

Peoria, Ill.—A new $500,000 factory will be erected by the Western Structural & Machine Works, recently incorporated.

Peru, Ill. — Peru Construction Co. has been awarded the contract to build an addition to the building now occupied by the Western Clock Co., the addition to have 33,000 ft. of floor space.

South Pekin, Ill. — The village board will advertise for bids for a lighting system, and will award a franchise to the most favorable bidder. Louis O. Dunkelberg, village attorney.

Vassar, Mich.—The council is planing ways and means to improve the light and water system. Address village clerk.

Montevideo, Minn. — The Sioux Falls-Pipestone electric transmission line has been practically completed as far as Dell Rapids and it is estimated that the line will be completed to serve Pipestone by the middle of October.

St. Paul, Minn.—Northern States Power Co. is now supplying the electrical energy requirements of the new St. Paul Athletic Club, amounting to about 287 hp. in motors.

Chetek, Wis.—Election will be held soon to submit to voters proposal to purchase distribution system of Chetek Light & Power Co.

Port Washington, Wis.—Plans are being made by Douglas Cahill, engineer, Gross building, Milwaukee, for an additional municipal power house. The plant will be 20x40 ft. and will cost about $30,000.

Waupaca, Wis. — Stock Co. will soon let contracts for a hydroelectric power plant. Address F. H. Josslyn, general manager, Algoma building, Oshkosh, Wis.

Hastings, Mich.—It is said that the General Motors Corp. has purchased the plant of the Hastings Consolidated Press & Tool Co. for $1,000,000 and that the capacity of the plant will be quadrupled to employ 1200 men.

Burlington, Iowa.—A special election will be held to vote on the question of issuing $30,000 bonds for municipal electric light plant. Address E. P. Weinstein, clerk.

Davenport, Iowa. — Tri-City Railway & Light Co. has been granted permission to install a transmission power plant from Brady street road at city limits, of Davenport to Five Mile house.

Monticello, Iowa. — Monticello Electric Co. is making improvements at its power plant which will cost $20,000. The new equipment will include two 112-kv-a. vertical type generators and also two vertical turbine water wheels. These two turbine water wheels will develop over 80% more power than that obtained from the wheels now in use.

St. Joseph, Mo.—St. Joseph Railway, Light, Heat & Power Co. will expend $1,000,000 in improvements and extensions. Address general manager.

Auburn, Neb.—Citizens have petitioned the city council asking for permission to hold a special bond election to extend the facilities of the municipal light plant so that it can enter into the business of furnishing commercial light and power.

Lincoln, Neb. — Plans now under consideration to install a power plant at the University of Nebraska Medical College to cost $60,000. Address Samuel Avery, president.

Minden, Neb.—$35,000 bonds have been voted to be used in the extension and improvement of the city light plant. Address city clerk.

Gregory, S. D.—At a special election $122,000 bonds for improvements to municipal electric light, waterworks, and sewer system bonds were carried.

SOUTH CENTRAL STATES.

Owensboro, Ky. — Kentucky Electric Lamp Co. has had plans prepared for the construction of a new three-story brick and concrete plant, about 60x100 ft., to provide for increased capacity. It is proposed to increase the output from about 3000 to 8850 lamps daily.

Birmingham, Ala. — Alabama Port Co., which has purchased property of Selma Lighting Co., will construct power lines between this city on the Coosa River, a distance of 57 miles.

Hobart, Okla.—$135,000 in bonds have been voted for an electric light plant. V. V. Long & Co., engineers, 1300 Colcord building, have prepared plans.

Perry, Okla.—City Council is considering plans for the issuance of bonds for $260,000, to cover the cost of improvements and extensions in the municipal electric light and water systems.

Tishomingo, Okla. — Engineers Johnson & Benham, Firestone building, Kansas City, will prepare plans for a light and water plant. F. L. Yarger, city clerk.

Dallas, Tex.—Dallas Hotel Co. will expend $20,000 enlarging the power plant of the Adolph Hotel. Address George W. Wells, supervising engineer, 4308 Washington boulevard, St. Louis, Mo.

WESTERN STATES.

Libby, Mont.—Tukens-Hazel Mining Co. is considering the construction of a power plant and 200-ton concentrator at its property 9 miles from here. Estimated cost, $200,000 and $240,000 concentrator.

Colorado Springs, Colo. — The Spruce street car line will be erected. The extension on the Spruce line calls for about 4 miles of trackage, to cost about $150,000. The whole proposition is only tentative at present and the outcome depends entirely upon the reports submitted by the engineers and surveyors. Should the line be extended on to the Stark-Corley lines, it would represent a large outlay of cash, as the road would have to cross several ravines, necessitating the building of a number of bridges. Address A. E. Carlton, president of the Pikes Peak Fuel Co.

Pueblo, Colo.—The city of LaJunta has decided to discontinue operation of its steam plant for pumping the city water supply and has contracted with the Arkansas Valley Railway, Light & Power Co. for electrical energy for this purpose.

Manti, Utah—City has authorized a bond issue of $20,000, the proceeds to be used to cover the cost of the construction of a new municipal electric light and power plant.

Kelso, Wash.—North Coast Power Co. has recently awarded a contract to N. A. Strand, Kelso, for the construction of a new brick substation near its office building. The company has also recently commenced the rebuilding of its power line from Kelso to Kalama, increasing the carrying capacity to 66,000 volts. The total cost of the work is estimated at about $40,000.

Seattle, Wash.—City Council has passed bill favoring extension and authorizing issuance and sale of

$1,350,000 light and power utility bonds to cover the cost of steam plant on Lake Union, adjoining present plant.

Tacoma, Wash. — City officials, in support of a proposed bond issue of $300,000 to purchase Lake Cushman power site on Skokomish river, state that the business of the municipal power plant has doubled in the last two years, and that the rate of increase is now about 33% annually. The Lake Cushman development, as outlined, will require an expenditure of about $6,500,000.

Tacoma, Wash. — Provided voters authorize bonds for the Lake Cushman power project, the city in constructing the 45-mile transmission line will erect a record breaking overhead span across the Narrows.

Bend, Ore.—T. H. Foley, manager of the local interests of the Bend Water, Light & Power Co., announces that the construction of a 1000-kw. steam plant to cost $100,000 will be started here within the next two weeks. It is expected the new plant which will double the power output of the power house here, will be completed by February, 1920. Plans for construction of a $125,000 plant on Tumble creek, work on which was to have started the latter part of the summer, will be halted until next summer.

Dallas, Ore. — Recent additions to the electrical energy load of the Dallas division of Mountain States Power Co. include an additional 25 hp. in motors for the Central Tile Co., and an addition at the gravel plant at Independence, making the Gravel plant's requirements 205 hp.

Klamath Falls, Ore.—California-Oregon Power Co., which has in progress the construction of a dam on Link river for water-power purposes, is defendant in a suit in the Federal court brought by the land owners who live near Upper Klamath lake. The plaintiffs seek to have the company enjoined from completing the dam, contending that the dam will raise the water in the lake to a height that will cause serious overflow of farm land. The company, however, claims it is only preparing to hold the water at flood level.

Portland, Ore.—The estimated expense of building an electric railroad from the St. Johns municipal terminal connecting with the Portland Railway Light & Power line and St. Johns is $30,000, according to figures compiled by Engineer Hegardt of public dock commission.

Roseburg, Ore.—William Polman, Baker, Ore., operating the local electric light and water plant, is arranging plans for extensive improvements to facilitate operations. It is also proposed to make improvements and alterations in the pumping and power plant on the North Umpqua river.

Avalon, Cal.—An election will soon be held to vote on an $88,000 bond issue for light and water plant construction.

Chico, Cal.—A surveying party will enter Chico canyon to make surveys of proposed site for a municipal power plant. Address F. S. Robinson, city engineer.

Fresno, Cal.—The Board of Supervisors of the county of Fresno of the Raisin City Lighting District of Fresno county invites and advertises for bids for furnishing, installing, maintaining and keeping in repair all necessary apparatus and caring for and maintaining the lights for Raisin City lighting district of Fresno county and for supplying district with electricity for operating and maintaining lights to be installed within district for a term of 5 years. Address D. M. Barnwell, clerk of board.

Los Angeles, Cal.—Contract has recently been awarded to H. H. Walker, Marsh-Strong building, for the installation of electric wiring, etc., in the new hotel building to be erected by the Wilshire Boulevard Hotel Co. on Wilshire boulevard, at cost of $27,612.

Los Angeles, Cal.—Pacific Electric Railway Co. has completed plans for the erection of a power plant at Los Angeles harbor. The structure is estimated to cost about $12,000.

Mayfield, Cal.—Town council is considering plans for the issuance of bonds for $20,000, to provide for the installation of a new electrical distributing system and $5000 for a new pump and motor equipment at the municipal water works.

Orange, Cal. — City trustees are having plans prepared for the installation of a new electric street-lighting system, ornamental type, on Glasswell street and Chapman avenue. About 157 standards will be required.

Oroville, Cal.—The Great Western Power Co. has awarded a contract to the Stone & Webster Co., Boston, for the construction of the proposed power plant at Caribou, near Belden.

Palo Alto, Cal.—City has authorized the issuance of bonds for $75,000, the proceeds to be used to cover the cost of the installation of a Diesel engine and generating unit at the municipal power plant. It is expected that the proposed work will be completed within 90 days.

Reedley, Cal.—Town Council recently awarded a contract to the Reedley Electrical Works for the installation of an electrolier system at $11,800.

San Diego, Cal.—San Diego Consolidated Gas & Electric Co. is making a short extension of its transmission line to furnish power to the city of San Diego for constructing a new $750,000 dam at Barrett, which will increase the city's water supply.

Whittier, Cal.—Southern California Edison Co. has had plans prepared for the construction of a one-story brick office and garage building, about 100x100 ft.

FOREIGN TRADE

[Addresses of firms referred to in these trade opportunities may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or its branch and local co-operative offices. Request for each opportunity should be on a separate sheet and the file number given.]

Electrical Goods (29,796). — The agency and purchase of novelties, hardware, food products, oleomargarine, lard presses, electrical goods, general merchandise, canning machinery and machinery to make tin cans are desired by a firm in Australia. References.

Electrical Implements (30,190).—A business man in France wishes to secure the representation of exporters of agricultural implements, machines, automobiles, electrical implements, and, in general, all industrial material. Correspondence should be in French.

Pumps (30,192).—The purchase of pumps of all sorts and pump machinery, such as a full line of turbine, centrifugal, and steam pumps, is desired by a firm in Spain. Quotations should be given c. i. f. Spanish city. Correspondence may be in English. References.

Electrical Goods (30,175).—A firm in Brazil desires to secure the representation of American steamship companies, and agencies for the sale of sugar mill machinery and supplies, glassware, paper, arms and ammunition, furniture, hardware, cement, line, drugs, electrical goods, paints, dyes, automobile tires, motorcycles and automobiles. Correspondence may be in English. Reference.

PROPOSALS

Cranes, Motors, Etc.—Bids will be received until 10:30 a. m., Sept. 2, by A. L. Flint, general purchasing agent, Panama Canal, Washington, D. C., for cargo handling cranes, air compressors, electric motor and spare parts, starting panels, motor-driven triplex pump, Hamilton-Corliss engine, fiber conduit bends, etc.

Motors—Bids will be received Sept. 3, at Room 406 City Hall, Chicago, for constructing and delivering f. o. b., two wound rotor induction motors with necessary starting apparatus, and other electrical equipment for the Chicago avenue pumping station, according to specifications on file in the office of Room 406, City Hall. Address Charles R. Francis, commissioner of public works.

Switchboards and Generator Equipment.—Until Sept. 4, bids will be received by J. H. McAlpin, mayor of Hollandale, Miss., for the installation of new switchboard and generator equipment at the municipal electric light plant, and for the furnishing of new street-lighting fixtures. Xavier A. Kramer, Magnolia, Miss., is consulting engineer.

Electrical Material.—The Bureau of Supplies and Accounts, Navy Department, Washington, D. C., will receive bids for 79 branch, composition boxes; 10,000 incandescent socket bushings; a miscellaneous quantity of midget push buttons; 50 lb. pressed plate, flexible, Grade A mica; 400 hard rubber, telephone transmitter mouthpieces, and 50 non-water-tight telephone plugs to be delivered at South Brooklyn, N. Y. (Schedule 4241), and 3000 mogul lamp sockets, for delivery at Portsmouth, N. H. (Schedule 4269).

Motor-Driven Pump.—The town of Leland, Miss., will receive until Sept. 2 bids for the boring of a 10-in. well, to be about 500 ft. deep with top, to be 16-in., to depth of about 100 ft. Well to be equipped with electric motor-driven pump and necessary machinery to deliver 600 gal. of water per minute. All bids must be accompanied by New York Exchange or cashiers' check for $500, and be in the hands of J. H. O'Quinn, town clerk, on or before 6 p. m., Sept. 2.

NEW PUBLICATIONS

"New Forms of Instruments for Showing the Presence and Amount of Combustible Gas in the Air" is the title of Scientific Paper 334, published by the Bureau of Standards, Department of Commerce. This paper contains a description of experimental work upon the combustion of gas at the surface of an electrically heated wire and the application of this phenomenon to the design of instruments for detecting the presence or indicating the amount of combustible gas in the air. The copy is now ready for distribution and those interested may obtain a copy by addressing a request to the Bureau of Standards, Department of Commerce, Washington, D. C.

INCORPORATIONS

New York, N. Y.—Monroe Electric Supply Co., Inc. Capital, $10,000. To manufacture electrical supplies. S. and J. Weiner, and J. A. Herman, 996 Home street, are the incorporators.

Buffalo, N. Y. — Mighty Manufacturing Co., Inc. Capital, $50,000. To manufacture electrical and mechanical devices. Incorporators: George N. Chaltas, E. Pappas, and E. L. Crabb, Buffalo.

Newark, N. J.—Amann & Finn. Inc. Capital, $50,000. To manufacture motors, etc. C. and E. F. Amann, Irvington, and D. J. Finn, New York, are the incorporators.

Harrison, N. J.—Gilby Wire & Dye Co. Capital, $125,000. To manufacture electrical wires, etc. Incorporators: Walter and Stanley Gilby, and T. W. Pell, Harrison.

New York, N. Y.—Humil Corp. Capital, $300,000. To manufacture electrical apparatus, etc. Incorporators: J. Van Harder, H. H. Thurlow, and F. D. Hagan, 55 Liberty street.

Hartford, Conn.—Perry Electric Co. Capital, $20,000. To operate a general electrical engineering and contracting establishment. Incorporators: E. C., G. W., and S. J. Perry, Hartford.

Philadelphia, Pa.—American Electric Storage Battery Co. Incorporated under Delaware laws with a capital of $1,000,000. To manufacture electric storage batteries. E. M. MacFarland, F. R. Hansell, Philadelphia; and J. V. Pimm, Camden, N. J., are the incorporators.

Burnsville, N. C.—Burnsville Electric Co. Capital, $15,000. To operate a local electric light and power plant. William C. Skaggs is the principal incorporator.

Greenville, S. C. — Piedmont Electric Co. Capital, $10,000. To manufacture electrical goods. R. E. Starnes is the principal incorporator.

Elkhart, Ind.—Mann Electric Co. has been incorporated with capital of $10,000, to engage in a general electrical contracting business. The incorporators are Vernon V. Mann, Fred Lemon and S. W. Long.

Walla Walla, Wash.—Lewiston and Walla Walla men have incorporated the Electric Equipment Co. The company will do a general business in electric light equipment. The incorporators are J. G. Harlan, C. O. Hawkinson and others.

West Point, N. D.—Bentinck Telephone Co. has incorporated with a capital of $1500. Address John Kuich.

Sioux Falls, S. D.—Electrical Brokerage Co. has incorporated with a capital of $100,000. It will manufacture, buy and sell and generally deal in electrical machinery and equipment and install electric light plants. The incorporators are W. L. Patterson, O. Shakstad, and E. S. Requa, of Sioux Falls.

Ivor, Va.—Ivor Light & Power Co. has incorporated with a capital of $5000. T. A. Saunders is president; L. C. Pulley, secretary and treasurer; H. M. Rawls, engineer.

Coon Valley, Wis.—Coon Valley Electric Co. has incorporated with a capital of $10,000. Incorporators are Anton Clum, Lizzie Bekkum and others.

Greenville, Ala.—Electric & Manufacturing Co. has incorporated with a capital of $50,000, to manufacture electrical specialties, etc. R. A. Beeland is the principal incorporator.

Dover, Del.—S. N. Blake & Co., Inc., has incorporated with a capital stock of $100,000, to operate various public utility companies, etc. Incorporators: Frank Jackson, W. I. N. Lofland, and C. L. Harmonson.

Dover, Del.—Dannenhauer, Inc., with a capital of $100,000, to manufacture electrical appliances, etc. Incorporators: W. A. Dannenhauer, G. H. Speakman, Wilmington; and J. J. Justice, Newport, Del.

Belleview, Fla.—Belleview Utilities Co. has incorporated with a capital of $25,000. Water works extension will be made, including galvanized iron pipes, wood frames, to cost $2500, to supply 23 families; electric double acting pump, 5000-gal. pressure system will be installed. Address Edw. S. Stench, secretary.

Champaign, Ill.—The Champaign Hotel Co. has been incorporated with a capital of $250,000 to erect reinforced concrete and steel hotel, to contain 156 rooms, specifications include special lighting plant.

Port Byron, Ill.—The Coe Light & Power Co. was incorporated with a capital of $10,000. It will furnish electric light and power in this village. Incorporators; S. L. Woodburn, Wm. Saddoris, and others.

Charlottesville, Ind.—Charlottesville Electric Light, Heat & Power Co. has been incorporated with capital of $5000. Address W. S. Lane, Charlottesville, Ind.

Berwick, Kan.—The Berwick Transmission Line Co. has been chartered with $25,000 capital by Nathias Strahm, E. T. Ukele and Norman Fike.

New York, N. Y.—Liberty Appliance Corp. has incorporated with a capital of $15,000, to manufacture electric and gas fixtures, etc. Incorporators: L. M. Rosenthal, J. Hohenstein, and Edward Meyer, St. Louis, Mo.

Mount Jewett, Pa.—Mount Jewett Electric Co. has incorporated with a capital of $25,000, to operate a local electric plant. W. H. Brown, Ridgway, is the principal incorporator.

Mount Pocono, Pa.—Mount Pocono Electric & Improvement Co. has incorporated with a capital of $20,000, to operate a local electric light and power system. W. J. Schaffer is the principal incorporator.

Portsmouth, Va.—Miller Bros. Electrical Co. has incorporated with E. R. Bardsdale president, and H. G. Walker, secretary.

Charlestown, W. Va.—Charlestown Heat & Light Co. has incorporated with a capital of $50,000. Incorporators: Jay Gates and others.

Syracuse, N. Y.—Hughes Electrical Construction Co. Capital, $25,000. To engage in electrical contracting. Incorporators: L. V., F. D., and J. J. Hughes.

New York, N. Y.—International Incandescent Lamp Works. Capital, $25,000. To manufacture electric lamps. Incorporators: I. Goldberg, C. Schickerling and C. F. Lyngass, Great Kills, S. I.

Somerville, Mass.—American Electric Co. Capital, $25,000. To manufacture electrical equipment. Incorporators: Joseph V. Pierce, Jay T. Cook and Almon W. Preble.

Chicago, Ill.—Wheeler Battery Co. Incorporated in Delaware with capital of $2,000,000. To engage in manufacturing, electrical engineering and contracting. Incorporators: Samuel C. Wood and Arthur M. Brody, Chicago.

Mount Oliver, Pa.—Walsh Storage Battery Co. has incorporated with a capital of $5000 to manufacture storage batteries. Morris Walsh, Knoxville, is the principal incorporator.

Summerville, S. C.—Summerville Public Service Co. has incorporated with a capital of $25,000. J. A. Guerin is one of the principal incorporators.

Hayesville, Ga. — Public Service Co. has incorporated with a capital of $125,000. Incorporators: G. H. Hairler and others.

Personals

Richard L. Wildauer Appointed Central District Manager Arrow Electric—J. A. Massie Retires—Other Changes

P. A. ERLACH has been named secretary of the Central Illinois Public Service Co., with headquarters at Springfield, Ill. Mr. Erlach has been serving as auditor for several years.

J. D. WHITTEMORE, general manager of the West Virginia Traction & Electric Co., Wheeling, W. Va., has recently been appointed receiver for the company by Judge Dayton, of the United States District Court.

GUY S. HAMILTON, advertising manager of the American Steam Conveyor Corporation, Chicago, has been appointed editor of the *Booster*, the corporation's newly established sales organ.

H. S. VALENTINE, for more than five years connected with the Link-Belt Co., has accepted the appointment of sales engineer in charge of Philadelphia territory for the American Steam Conveyor Corp.

R. A. CREWS, of Charleston, Ill., has been named auditor of the Central Illinois Public Service Co., with headquarters at Mattoon, Ill. He will succeed P. A. Erlach, who has been named secretary.

THOMAS O. MORGAN, until recently head of the service department of the New York office of the American Steam Conveyor Corp., has been promoted to the position of sales engineer and will handle Long Island and Connecticut territory.

H. R. WICKERSHAM, Allentown, Pa., manager of the local branch of the electrical contracting firm of the Macan Jr. Co., recently tendered an interesting address on the development of the uses of electricity at the meeting of the Kiwanis Club at the Hotel Allen.

WILLIAM S. MURRAY, for many years chief electrical engineer of the New York, New Haven & Hartford Railroad and recently president of the Hoosatonic Power Co., which supplies power to some of the lines of the Connecticut company, has opened an office as consulting engineer in New York.

A. S. WITMER, formerly of the commercial department of the Louisville Gas & Electric Co., has been selected to head the million dollar Industrial Foundation. The Foundation under the leadership of Tampton Aubuchon has secured the location of 25 new factories in Louisville during the past two years.

W. P. NASER, manager of the Trumbull Electric Manufacturing Co., Chicago, has tendered his resignation to take effect in October, 1919. He has been connected with the Trumbull company for nearly seven years. He opened a branch for the company in San Francisco during the World's Fair and was later promoted to the larger Chicago branch. "Bill" Naser is well known in the Middle West, the South and on the Coast.

B. C. Condit, who served several years as construction engineer for the Northwestern Electric Co., Portland, Oregon, within which period the company's steam-electric plants were built, now occupies the position of consulting engineer for the same concern.

RICHARD L. WILDAUER, formerly assistant sales manager, Arrow Electric Co., Chicago, has been appointed manager of the central district for the Arrow company, succeeding E. M. Scribner. Mr. Wildauer has a wide acquaintance in the electrical field, especially in the Middle West, and his many friends unite in expressing gratification over his well deserved promotion. He has been connected with the Arrow Electric Co. in the Chicago territory for the past 10 years and previous to that was with the American Circular Loom Co., Chicago, for two years.

Richard L. Wildauer.

J. A. MASSIE, for several years sales manager for the Hoyt Electrical Instrument Works, Penacook, N. H., has retired from active service with the company and will take a long and well earned rest. He will, however, continue to be identified with the organization through his interest in the Burton-Rogers Co., which has been made the sales department of the Hoyt Electrical Instrument Works, M. T. Rogers taking over Mr. Massie's duties.

CHARLES S. RUFFNER, vice-president and general manager of the Union Electric Light & Power Co., St. Louis, has been elected a director and vice-president of the North American Co., New York, the controlling company of the St. Louis utility. Mr. Ruffner relinquished the local management of the St. Louis subsidiary when accepting the appointment with the parent company. He retains the offices, however, of vice-president of the Union Electric Light & Power Co. and the St. Louis County Gas Co. and president of the American Light & Power Co., St. Charles, Mo., the Commercial Telephone Co. and the Arrow Engineering Co., all of which are subsidiaries of the North American Co. Mr. Ruffner was born in Chicago in 1880 and was graduated from the University of Missouri in 1900 with the degree of Bachelor of Science in electrical engineering. He entered the engineering profession with the Telluride Power Co. and Central Colorado Power Co. doing large power transmission work, and since 1911 has been an officer of subsidiaries of the North American Co. He is a manager and fellow of the American Institute of Electrical Engineers and a member of the American Electrochemical Society. He was also appointed associate member of the Naval Consulting Board in 1916.

FREDERICK S. DELLENBAUGH, Columbia University, 1910, ARTHUR L. NELSON, Massachusetts Institute of Technology, 1915, and F. B. PHILBRICK, Massachusetts Institute of Technology, 1918, have been appointed instructors in electrical engineering at the Massachusetts Institute of Technology. Mr. Dellenbaugh was a captain of the Signal Corps in overseas service during the war. He was graduated from the electrical engineering course at Columbia, and has been in the employ of the Crocker-Wheeler Manufacturing Co. and the Westinghouse Electric & Manufacturing Co. in the departments of design and commercial engineering. His particular duties in his new appointment will be in the teaching of dynamo design and the mechanical applications of electric power. Mr. Dellenbaugh will also give a portion of his time to research along lines relating to electrical machinery. Mr. Nelson was graduated from the electrical engineering course of the Massachusetts Institute of Technology. During the war he was a lieutenant in the Engineer Corps of the Navy with important work relating to construction of power plants and supply of power at the submarine base. After graduating he had experience with the C. H. Tenney Co. in construction and operation of electric plants. Mr. Nelson's work will be instruction relating to central stations and distribution systems. He will also carry on some work as a consulting engineer. Mr. Philbrick since graduating has been in the employ of the General Electric Co. His work at the Institute will be instruction in electrical measurements under the direction of Professor Laws and carrying on researches relating to electric circuits which Professor Laws has on hand.

Principles of Booster Transformers

The Elements of Boosting and Choking by Transformers—Formulas for Finding the Percentage of Boosting and Choking of Single-Phase and Polyphase Transformers Under Different Conditions

By C. M. JANSKY

Associate Professor of Electrical Engineering, University of Wisconsin, Madison, Wis.

IT IS quite common practice to use transformers for temporarily boosting the voltage to compensate for line drop. Tables have been prepared showing the percentage of boosting obtained by using transformers of different ratios and different connections. The writer, however, has been able to find in print very little of the fundamental principles of calculating the boosting effect under different conditions. This may be due to the fact that the principles are quite simple, and hence explanations may seem unnecessary. Nevertheless, they are often misunderstood and, as some of the tables are inaccurate, an analysis of the principles may be appropriate.

The time-phase difference between the primary and secondary voltages of a transformer is one-half a period. If we represent the two voltages by vectors on a clock diagram they are 180° apart. It is thus evident that when the primary and secondary windings of a transformer are connected in series, their electromotive forces will be either added together or subtracted one from the other, depending upon the connections employed. This is the fundamental principle of the booster and choke transformer.

The percentage of boosting or choking will be determined by the manner in which the coils are interconnected, and will also depend upon the interconnection of the circuits.

The simpler connections of single-phase transformers for boosting the voltage are shown in Figs. 1 and 2. In Fig. 1a the secondaries are connected in parallel and one end of the primary winding is connected directly to the secondary and the other end of the secondary winding is then connected to the line. The voltage across the line on the secondary side is the algebraic sum of the primary and secondary voltages. This is known as straight or simple boosting. The connections shown in Fig. 1b differ from those in 1a in that the primary is connected to the far side and the booster itself is subjected to the boosted voltage. Fig. 2 shows similar connections for the secondary coils in series.

Percentage of Boosting.—The percentage of boosting may be calculated as follows:

Let R = ratio of transformation,
E_1 = primary voltage,
E_2 = secondary or load voltage.

The percentage of boosting will depend upon the connections employed, hence two cases must be considered. When the connections of Fig. 1 (a) are used, the secondary voltage is evidently given by

$$E_2 = E_1 + \frac{E_1}{R} = E_1 \frac{R+1}{R} \quad \ldots\ldots (1)$$

and percentage boosting $= \frac{E_2 - E_1}{E_1} \times 100 = \frac{100}{R} \ldots (2)$

When the connections shown in Fig. 1 (b) are employed the secondary pressure is given by

$$E_2 = E_1 + \frac{E_2}{R}$$

or $E_2 = \frac{E_1 R}{R-1}$ ....(3)

The percentage of boosting $= \frac{E_2 - E_1}{E_1} \times 100 = \frac{100}{R-1}$ (4)

Example.—A transformer whose ratio is 10 to 1 is used as an augmented booster. If the primary voltage is 2200, what is the load voltage, and what is the percentage of boosting?

Since $E_2 = \frac{E_1 R}{R-1}$

we have $E_2 = \frac{2200 \times 10}{9} = 2444$ volts.

Percentage boosting $= \frac{100}{9} = 11.1\%$.

The percentage of boosting by a simple booster would be 10%.

Booster Transformer on Polyphase Circuits.

The effect of boosting transformers on polyphase systems will be modified by the connections employed.

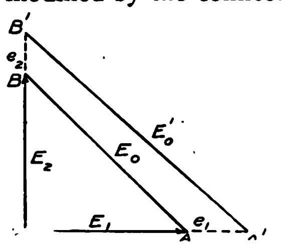

Fig. 3.—Three-Wire, Two-Phase Booster Diagram.

Since a four-wire two-phase system is the same as two single-phase systems, the process of calculating the boosting effect on such a system is exactly like that on single-phase circuits.

When three-wire two-phase systems are used the boosters are inserted into the outside wires. The percentage of boosting between either outside wire and

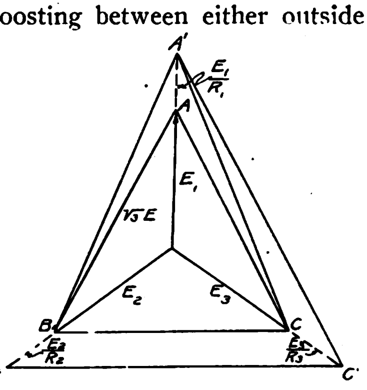

Fig. 4.—Y-Connected Three-Phase Network with One Phase Boosted.

the neutral is the same as for single-phase circuits. The increase in the voltage between the outside wires will be the same percentage as the phase voltages when these are boosted the same percentage. If, however, the phase voltages are raised by different amounts, then the voltage between the outside wires will also be increased by a different percentage. In Fig. 3, let $OA = E_1$ and $OB = E_2$ be the phase voltages, and let E_1 be boosted by E_1/R_1 and E_2 by E_2/R_2. Since $E_1 = E_2$

$$A'B' \text{ or } E_0' = \sqrt{\left(E_1 + \frac{E_1}{R_1}\right)^2 + \left(E_1 + \frac{E_1}{R_2}\right)^2}$$

$$= E_1 \sqrt{2 + \frac{2}{R_1} + \frac{2}{R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} \quad \ldots\ldots (5)$$

And percentage of boosting

$$= \frac{100}{\sqrt{2}} \left\{ \sqrt{2 + \frac{2}{R_1} + \frac{2}{R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} - \sqrt{2} \right\} \ldots (6)$$

When $R_1 = R_2$, this reduces to $\frac{100}{R}\%$. When $R_1 = \infty$, or when only one phase is boosted, then the percentage of boosting becomes

$$\frac{100}{\sqrt{2}} \left\{ \frac{1}{R} \sqrt{2R^2 + 2R + 1} - \sqrt{2} \right\} \ldots\ldots (7)$$

By substituting $R-1$ for R, the above formulas will give the percentage boosting when the augmented booster connections are used.

The calculation of the boosting effect in a three-phase system is not so simple as in the single-phase system and it also depends upon the type of circuits employed. In a Y-connected four-wire system, each phase voltage may be boosted separately by connecting a booster into the phase wire. In this case the percentage boosting is calculated in exactly the same way as for single phase.

The effect of the booster on the voltage between phase wires may be calculated by the aid of Fig. 4, where E_1, E_2 and E_3 represent the voltages between phase wires and neutral, and AB, BC and CA represent the phase voltages, respectively. When E_1 is boosted the voltages between A and B, C and A, are both increased the same percentage, while that between B and C is unaffected. Now

$$(A'B)^2 = E_2^2 + \left(E_1 + \frac{E_1}{R_1}\right)^2 - 2E_2\left(E_1 + \frac{E_1}{R_1}\right) \cos 120^\circ$$

$$= E_2^2 + E_1^2 + \frac{2E_1^2}{R_1} + \frac{E_1^2}{R_1^2} + E_2E_1 + \frac{E_1E_2}{R_1}$$

$$= E_1^2 + E_1^2 + \frac{2E_1^2}{R_1} + \frac{E_1^2}{R_1^2} + E_1^2 + \frac{E_1^2}{R_1}$$

$$= 3E^2 + \frac{3E_1^2}{R_1} + \frac{E_1^2}{R_1^2}$$

$$= 3E_1^2 \left(1 + \frac{1}{R_1} + \frac{1}{3R_1^2}\right)$$

Therefore $A'B = \sqrt{3}\, E_1 \sqrt{1 + \frac{1}{R_1} + \frac{1}{3R_1^2}}$

and the percentage boost

$$= \left(\frac{1}{\sqrt{3}R} \sqrt{3R^2 + 3R + 1} - 1\right) 100 \text{ per cent.} \ldots (8)$$

If E_3 is boosted the same per cent as E_1, it is evident that the voltage between C and A is boosted the same per cent. The percentage boost for BC is given by (8).

The boosting of the voltage of one phase of a three-wire three-phase system affects the voltage in two phases, but to a different extent; and when the voltage of two phases is boosted, all three are boosted, but no two alike. The connections for a simple three-wire three-phase booster are shown in Fig. 5. The relations between the line voltages on the generator side are represented by the equilateral triangle, Fig. 6, where E_1, E_2 and E_3 represent the voltages between lines AB, BC and CA, respectively. Suppose that the ratios of transformers 1, 2 and 3 are R_1, R_2 and R_3, respectively; then each phase voltage will be boosted a different amount and the resulting load voltages will be represented by the triangle $A^1B^1C^1$, Fig. 6.

Let $e_1 = \frac{E_1}{R_1}$

$e_2 = \frac{E_2}{R_2}$

and $e_3 = \frac{E_3}{R_3}$

Then
$$(E_1^1)^2 = (E_1 + e_1)^2 + e_2^2 - 2e_2(E_1 + e_1)\cos 120^\circ = (E_1 + e_1)^2 + e_2^2 + e_2(E_1 + e_1)$$

Likewise $(E_2^1)^2 = (E_2 + e_2)^2 + e_3^2 + e_3(E_2 + e_2)$

and $(E_3^1)^2 = (E_3 + e_3)^2 + e_1^2 + e_1(E_3 + e_3)$

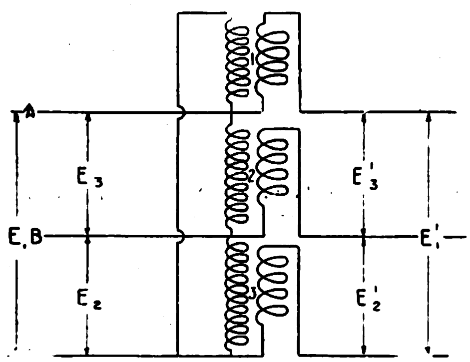

Fig. 5.—Connections of a Simple Delta-Connected Three-Phase Booster.

Since $E_1 = E_2 = E_3$, the subscripts may be dropped and upon substituting E/R_1 for e_1, E/R_2 for e_2, and E/R_3 for e_3, and reducing we get

$$E_1' = E\sqrt{1 + \frac{2}{R_1} + \frac{1}{R_2} + \frac{1}{R_1R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} \quad \ldots\ldots (9)$$

The percentage of boosting becomes

$$100\left\{\sqrt{1 + \frac{2}{R_1} + \frac{1}{R_2} + \frac{1}{R_1R_2} + \frac{1}{R_1^2} + \frac{1}{R_2}} - 1\right\} \quad \ldots\ldots (10)$$

In the same way,

$$E_2' = E\sqrt{1 + \frac{2}{R_2} + \frac{1}{R_3} + \frac{1}{R_2R_3} + \frac{1}{R_2^2} + \frac{1}{R_3^2}} \quad \ldots\ldots (11)$$

and
$$E_3' = E\sqrt{1 + \frac{2}{R_3} + \frac{1}{R_1} + \frac{1}{R_1R_3} + \frac{1}{R_1^2} + \frac{1}{R_3^2}} \quad \ldots\ldots (12)$$

The percentage of boosting may be calculated by formulas similar to formula (10).

In many cases these formulas can be simplified, as when R_2 and $R_3 = \infty$, from (9) we have

$$E_1' = E\sqrt{1 + \frac{2}{R_1} + \frac{1}{R_1^2}} = E\sqrt{\frac{R_1^2 + 2R_1 + 1}{R_1^2}} = \frac{E(R_1 + 1)}{R_1} \quad \ldots\ldots (13)$$

and percentage of boosting

$$= \frac{100}{R_1} \text{ as for single phase} \quad \ldots\ldots (14)$$

In the same case (when R_2 and $R_3 = \infty$) substituting in (11) we find $E_2^1 = E$ and percentage of boosting is zero; in the same case, substituting in (12) we find

$$E_3' = E\sqrt{1 + \frac{1}{R_1} + \frac{1}{R_1^2}} = \frac{E}{R_1}\sqrt{R_1^2 + R_1 + 1} \quad \ldots\ldots (15)$$

and percentage of boosting is

$$100\left\{\frac{\sqrt{R^2 + R + 1}}{R} - 1\right\} \quad \ldots\ldots (16)$$

When $R_1 = R_2$ and $R_3 = \infty$, then from (9) we find

$$E_1' = E\sqrt{1 + \frac{3}{R_1} + \frac{3}{R_1^2}} = \frac{E}{R}\sqrt{R^2 + 3R + 3} \quad \ldots\ldots (17)$$

and percentage of boosting is

$$100\left\{\sqrt{1 + \frac{3}{R_1} + \frac{3}{R_1^2}} - 1\right\} \quad \ldots\ldots (18)$$

also from (11)
$$E_2' = E\sqrt{1 + \frac{2}{R_2} + \frac{1}{R_2^2}} = E\sqrt{\frac{R_2^2 + 2R_2 + 1}{R_2^2}} = \frac{E(R + 1)}{R}$$

and percentage of boosting is $\frac{100}{R}$.

also from (12)
$$E_3' = E\sqrt{1 + \frac{1}{R_1} + \frac{1}{R_1^2}} = \frac{E}{R_1}\sqrt{R_1^2 + R_1 + 1}$$

and percentage of boosting is

$$100\left\{\frac{1}{R}\sqrt{R_2^2 + R + 1} - 1\right\} \quad \ldots\ldots (20)$$

When $R_1 = R_2 = R_3$, it is evident that $E_1^1 = E_2^1 = E_3^1$ and that the percentage of boosting is the same for each phase and is given by formula (18) above.

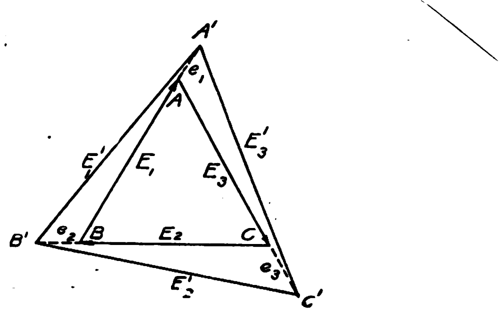

Fig. 6.—General Case of a Delta Three-Phase Booster with Unequal Boosting of Each Phase.

The same formulas may be used for calculating the boosting effect when augmented booster connections are used. It is only necessary to change R to $(R - 1)$.

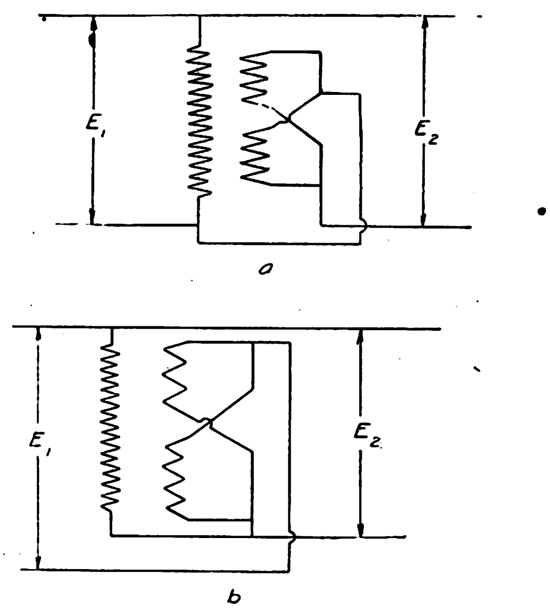

Fig. 7.—Single-Phase Choking Transformer with Secondary Coils in Parallel.

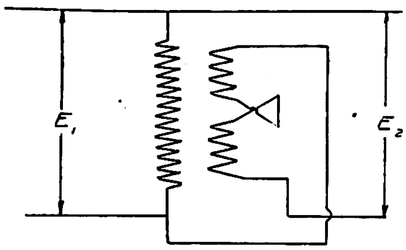
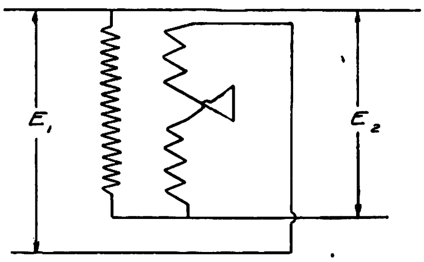
CHOKING CONNECTIONS.

If the secondary winding is connected so that its voltage opposes the primary voltage, the line voltage will be reduced. A transformer so connected is known



a



b

Fig. 8.—Single-Phase Choking Set with Secondary Coils in Series.

as a choking transformer. The connections for choking that correspond to the boosting connections, Figs. 1 and 2, are shown in Figs. 7 and 8.

The methods of calculating the choking effect are the same as for boosting. When the connections are as shown in Fig. 7 (a) the load voltage $E_2 = E_1 - \frac{E_1}{R}$

$$= \frac{E_1 (R-1)}{R}$$

$$\text{Percentage choking} = 100 \left\{ \frac{E_1 - \frac{E_1 (R-1)}{R}}{E_1} \right\} = \frac{100}{R} \ldots\ldots (21)$$

When the connections are as shown in Fig. 7 (b) the load voltage is $E_2 = E_1 - \frac{E_2}{R}$

$$= \frac{E_1 R}{R+1}$$

$$\text{Percentage of choking} = \frac{100}{R+1} \ldots\ldots\ldots\ldots\ldots (22)$$

A brief analysis will show that the formulas for the effect of boosting in polyphase systems may be used for calculating the diminishing effect, provided the terms containing the first powers of R have their signs changed. Thus the choking formulas for a three-wire two-phase system become

$$E_0' = E_1 \sqrt{2 - \frac{2}{R_1} - \frac{2}{R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} \ldots\ldots\ldots\ldots (23)$$

and percentage choking

$$= \frac{100}{\sqrt{2}} \left\{ \sqrt{2 - \frac{2}{R_1} - \frac{2}{R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} - \sqrt{2} \right\} \ldots\ldots (24)$$

Formulas (23) and (24) correspond to (5) and (6) for boosting.

When $R_1 = R_2 = R$, (24) reduces to $-\frac{100}{R}$%.

When one phase alone is choked, that is, either R_1 or $R_2 = \infty$, (24) becomes

$$\frac{100}{\sqrt{2}} \left\{ \frac{1}{R} \sqrt{2R^2 - 2R + 1} - \sqrt{2} \right\} \ldots\ldots\ldots\ldots\ldots\ldots (25)$$

In the same way, the formulas (9), (11) and (12) for boosting on three-wire three-phase circuits upon changing signs become

$$E_1' = E \sqrt{1 - \frac{2}{R_1} - \frac{1}{R_2} + \frac{1}{R_1 R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} \ldots\ldots (26)$$

$$E_2' = E \sqrt{1 - \frac{2}{R_2} - \frac{1}{R_3} + \frac{1}{R_2 R_3} + \frac{1}{R_2^2} + \frac{1}{R_3^2}} \ldots\ldots (27)$$

$$E_3' = E \sqrt{1 - \frac{2}{R_3} - \frac{1}{R_1} + \frac{1}{R_1 R_3} + \frac{1}{R_1^2} + \frac{1}{R_3^2}} \ldots\ldots (28)$$

and percentage choking for (26) becomes

$$= \left\{ 1 - \sqrt{1 - \frac{2}{R_1} - \frac{1}{R_2} + \frac{1}{R_1 R_2} + \frac{1}{R_1^2} + \frac{1}{R_2^2}} \right\} 100$$

When $R_1 = R_2 = R_3 = R$, the percentage choking is the same for each phase and is given by

$$\left\{ 1 - \frac{1}{R} \sqrt{R^2 - 3R + 3} \right\} 100$$
